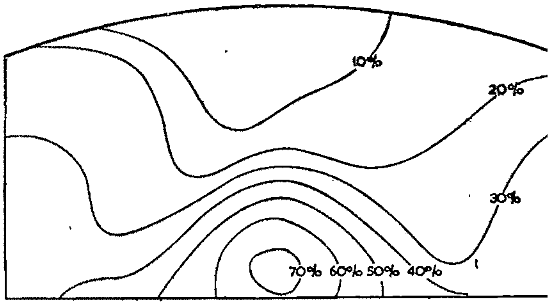
In the apparatus used, air is passed into the i takes and ports of the model at measured rates. small quantity of carbon dioxide from a cylinder introduced into the gas port line. Samples are tak from the furnace by a probe connected by rubb tubing to the sample tube of the infra-red gas analys A small pump provides suction at the outgoing en of both sample and control tube. The latter dra air continuously from the duct supplying air to t air ports, and a two-way tap enables the sample tu to be connected at will to the gas port supply li Each of these systems is arranged to be similar length and speed of aspiration.

At the start of the experiment the sensitivity co trol of the analyser is adjusted to correspond wi the calibration curve provided by the makers[4]. T rate of flow of carbon dioxide is then increased un full-scale deflexion is obtained with the sample tak from the gas port line. This is checked betwe each reading. The probe is placed in predetermin positions and the readings taken and plotted as co tours of equal concentration.

The work, not yet complete, from which the ill trations are taken is designed to supplement that do by the Steelmaking Division of this Association, the effect of furnace design on gas and air mixi on heat transfer to the hearth[5].

Fig. 1



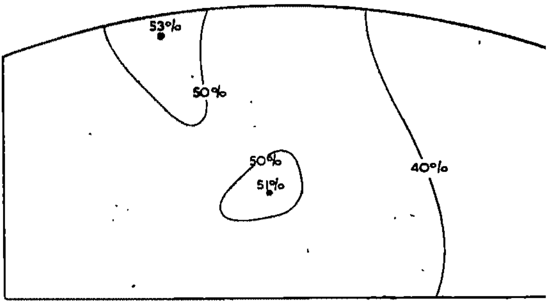


Fig. 2

The accompanying two graphs show the effect o modification of air port design. Both represe vertical sections across basically similar furnaces the first charging door. Fig. 1 represents the co ventional design, in which points to be noted a the slow mixing shown by the high concentration unburnt gas, the position of the flame close to t hearth, and the flow of air down the centre of t roof. Fig. 2 shows a rejected modification. Mixi is very good; but the higher concentration near t roof, especially when compared with similar sectio near the end wall, indicate that the flame has be blown up to the roof, and this in practice would so cause the roof to melt. It is to be noted that t asymmetry with respect to the centre line is in agre ent with the work of Mr. A. R. Philip[6] in visualizing e flow pattern in open hearth furnaces.

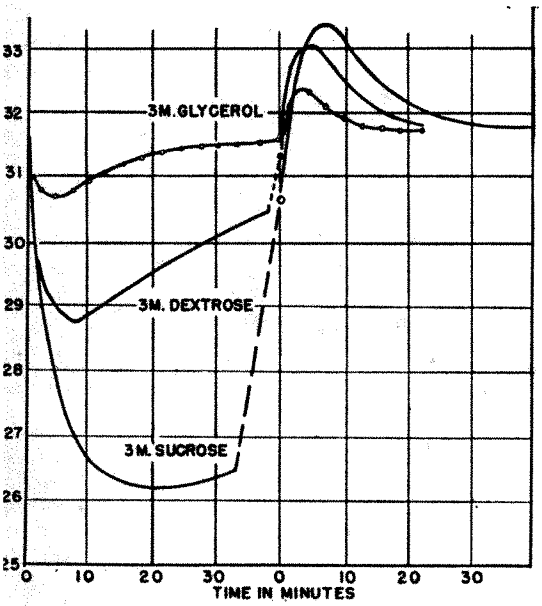
Ionic Exchange and Fibre Contraction

In a communication under the above title, pubhed in *Nature* of May 31, 1947, p. 746, J. L. Mongar d A. Wassermann report some experiments on the -swelling of calcium alginate fibres in salt solutions. ey noted that water-swollen alginate fibres when aced in various alkali-salt solutions first contract d then increase in length. The authors suggest at the contraction results from destruction of lcium ion cross-links between alginate chains as e calcium is replaced by alkali ions. They propose so that plastic flow is mainly responsible for the al swelling effect.

In the course of studies carried out some time ago, e found that water-swollen cellulosic fibres when aced in aqueous salt solutions also contract rapidly first and then re-swell. The same phenomenon curs in sugar or glycerol solutions. Some typical servations on water-swollen hydroxyethyl cellulose onofils (0·3 mole hydroxyethyl/glucose unit) are own in the accompanying graph.

We believe that the contraction is caused by water igrating out of the filament to establish osmotic uilibrium. Eventually, as the solute diffuses into e filament, the osmotic forces are reversed and ter flows into the filament, causing an increase in length. It appears to us that the same processes are probably responsible for the shrinking – swelling phenomenon of calcium alginate fibres in salt solutions. If this is true, then considerations of cross-linking and plastic flow are unnecessary.



e-swelling in sugar and glycerol solutions

Re swelling in water after equilibrium established in sugar and glycerol solutions

e-swelling of hydroxyethyl cellulose monofil (0·3 mole hydroxyethyl/glucose unit). Gel monofil dried, then re wet in water

Flory[1], Hermans[2], and others have developed theories which consider swelling as being an osmotic phenomenon. According to these theories, which appear to be applicable in the present case, swelling is related to the entropy of chain configuration, and equilibrium is established when osmotic entropy and entropy of chain configuration are equal (neglecting heat of mixing). If osmotic entropy is changed by adding a solute to the swelling liquid, the swollen structure will shrink. If a solute diffuses into the swollen structure, osmotic entropy changes and swelling will increase. This can be demonstrated quite simply by allowing a cellulose monofil to come to equilibrium with a sugar solution and then placing it in water, as indicated in the graph. Water migrates in to establish equilibrium with sugar molecules in the swollen cellulose structure, increasing its swelling beyond the water-swollen state. As the sugar molecules diffuse out of the gel, it gradually returns to its original water-swollen dimensions.

The Potato Caterpillar Pest (*Agrotis* spec.) of Tristan da Cunha

The reports of the Norwegian Scientific Expedition to Tristan da Cunha (1937–38) and of the naval authorities who were stationed on the island during the Second World War have directed attention to the fact that the potato crop, on which the islanders depend so much for food, was seriously affected by the ravage of a caterpillar. Before the departure of the recent expedition sent to the islands by a group of South African fishing interests, it was impossible to find out more about this pest.

As members of this expedition, which left Cape Town on January 29 in the M.V. *Pequena*, it was one of our tasks to study the 'potato grub' problem and to try to find a method of control. We were informed by the Rev. C. P. Lawrence and islanders that the pest had only been noticed since the old custom of using kelp (consisting chiefly of *Macrocystis pyrifera*, Ag., and a small amount of *Ecklonia* sp.) as manure for the potato patches was abandoned and sheep manure used instead. If this observation be accurate, it suggests an interesting line of research, for the kelp would seem to render the soil unsuitable for the development of the caterpillar. In the one month available such a line of research could not be followed, but time did permit the testing of the effects of insecticides on the caterpillars.

We found that only one species of insect was responsible for the damage. Dr. A. J. T. Janse of the University of Pretoria, who was kind enough to examine material of the species, has come to the conclusion that the species is not like any that he knows from Europe or South Africa and, therefore, has not been able to name the species.

Badly defoliated potato plants after having been attacked by the caterpillars. (Photograph by Dr. G. J. Broekhuysen)

The damage done by the caterpillars is very serious, and although we were told that the infestation this season was less than usual, we were none the less impressed by the heavy damage caused. Many patches had been completely defoliated and caterpillars were eating the haulms of the defoliated plants (see photograph). In South Africa this species is not often found on potatoes, nor does it attack the foliage of the various plants on which it occurs; but feeds on the stem at soil-level.

On our arrival in the beginning of February, most of the caterpillars were in the last two instars; but by the time we left a month later, fairly large numbers of very young caterpillars had appeared, indicating a new generation. They chiefly attacked the plants during the night, and on dry days most of them burrowed into the soil at the foot of the plants. On damp days, however, many remained feeding. This habit is well known to the islanders, who send the children in the early morning to pick the caterpillars off the plants and crush them. The caterpillars were not confined to the potato, but were found feeding on a variety of plants, including grasses, thistles, *Rumex* spp., and most vegetables, except pumpkins, tomatoes, strawberries, onions and parsley. Apart from the low settlement plateau with its potato patches, the caterpillars were also found at Cave Point and Sandy Point, both of which are uninhabited. None was found on the high plateau (about 2,000 ft.) or higher up on the mountain.

The effects of three insecticides were tested in cage experiments and two in the field. *Lead arsenate* gave an unsatisfactory average mortality of 35·1 per cent in three sets of cage experiments and is also too dangerous for a backward community such as that on Tristan da Cunha to apply; it was not tried in the field. *Sodium silicofluoride*, given as a bait mixed with bran (1 in 12 by weight), gave an average mortality of 78·2 per cent in five sets of cage experiments and up to 71·6 per cent mortality in three sets of field-tests. In one of the field-tests the concentration of the poison was cut down by half. *Wettable D.D.T.* (50 per cent), in a spray (1 ounce per gallon), gave an average mortality of 88· per cent in four cage experiments and 99·1 per cen in three field-tests. Again in the last field-test th concentration of the solution was cut down by hal

Unfortunately, the number of field-tests is rathe limited; but they show nevertheless quite distinctl that the pest can be controlled by the use of eithe D.D.T. spray or sodium silicofluoride – bran bait, o by using them alternately. It will also be advisabl to control the pest on the surrounding vegetatio perhaps by the introduction of some insectivorou bird. The local thrush (*Nesocichla eremita eremita* Gould.), or 'starchy' as the islanders call it, wa found to be very fond of the caterpillars. Unfortun ately, the large number of rats have nearly exterm inated this bird on Tristan. If the rat menace coul be checked the thrushes might increase, and in an event their numbers could be augmented from th flocks on the neighbouring islands of Nightingale an Inaccessible.

A full account of the experiments conducted wi be submitted for publication to the *Journal of th Entomological Society of Southern Africa.*

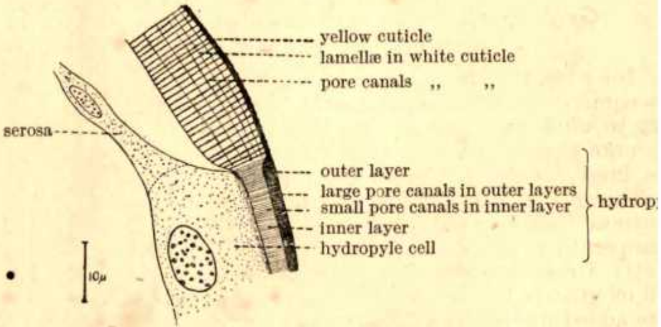
Pore Canals in the Egg Membranes of *Locustana pardalina* Walk.

IT has been shown by Slifer[1] that in the egg *Melanoplus differentialis* water is taken up through small, circular, specialized area (the hydropyle) in tl yellow cuticle. This structure, consisting of tw layers, is situated at the posterior tip of the eg and is a secretory product of a group of enlarge serosal cells (hydropyle cells). According to h description, these two layers are continuous with tl so-called yellow and white cuticles which cover tl remainder of the egg. The outer layer of the hydr pyle is several times thicker than the correspondi layer of the unspecialized yellow cuticle and is al distinctly striated. These striations (pore canals) ru at right angles to the surface. Slifer also describ the inner layer of the hydropyle as being continuo with the white cuticle and of the same structure.

In the egg of the South African brown locu (*Locustana pardalina*) the structure of the out layers of the hydropyle corresponds in every deta to that of *Melanoplus*. The substance of the inn layer, however, appears to be more homogeneo than the white cuticle of the unspecialized part



Semi-diagrammatic representation of the posterior tip of the egg of *L. pardalina* showing a small portion of the hydropyle region and adjacent unspecialized yellow and white cuticles the egg and contains a series of very small pore canals which penetrate this layer at right angles, linking up with the larger pore canals in the outer layer. These small canals are very difficult to demonstrate, but they show up distinctly in paraffin sections slightly verstained in hæmatoxylin. This suggests that they contain cytoplasmic filaments originating in the underlying hydropyle cells. The white cuticle of the remainder of the egg is distinctly laminated, and like the inner layer of the hydropyle it also contains pore anals but of a much larger size.

A detailed account of these and other features of he egg of *Locustana* will appear elsewhere.

Control of Intestinal Microflora

IN view of recent work which has directed attention o the importance of the intestinal microflora in nutrition, examinations of the fæces were made on a number of children receiving treatment with treptomycin.

Films showed a fair proportion of Gram-negative bacilli; but in most cases none could be grown. In other cases, streptomycin-resistant strains of *A. ærogenes* were found on culture. In no case could any *B. coli* or Gram-negative bacillus other than *A. ærogenes* be grown.

A strain of smooth *B. coli* was made streptomycin-resistant, and after attempts at inoculation by mouth had failed, rectal inoculation was successful. This has now been carried out on two cases, and in each case the organism appeared in the stools in less than 48 hours; in one case it persisted until treatment was uspended (11 days), and in the other case it is still present at the time of writing (16 days). It is now only just resistant to 10–20 units of streptomycin per ml.

This technique may be useful in assessing the part played by various other species of micro-organisms in nutrition; and also possibly in epidemiological problems.

My thanks are due to Prof. W. F. Gaisford for his ready co-operation, and to my laboratory steward, Mr. H. Ward, for his untiring assistance.

Growth of *Culex molestus* under Sterile Conditions

Aedes ægyptii and *Culex pipiens* are the only two mosquitoes which have hitherto been reared from egg to adult under sterile conditions. It is interesting o note that the autogenous *Culex molestus* can also be bred without difficulty on sterile media.

The following media were found suitable for this purpose (all experiments were carried out at a temperature of 28° C.).

(1) Dried or fresh yeast (autoclaved) 1·2 gm. to 5 ml. distilled water to which 25 eggs of *C. molestus* were added under sterile conditions. On this medium he mosquitoes developed from eggs to adult in 0·5–13 days, but the adults were not viable.

(2) Water plus dried yeast plus the following vitamins: thiamin, riboflavin, pantothenic acid, niacin, pyridoxin, folic acid (each 10 γ per ml.), biotin 0·14 γ per ml. This was the optimum medium, and the development from egg to adult lasted 7·5 days. The mosquitoes were viable. Obviously 1·2 gm. of the best samples of yeast available did not contain sufficient of the above factors to produce viable adults.

(3) Liver extract plus dried yeast (autoclaved) (Trager's medium for *A. ægyptii*). Development from egg to adult lasted 14 days and the adults were viable. Water extract of the same yeast and liver extract allowed development from egg to adult in 20 days; but the adults which emerged were not viable.

(4) Water, glucose (0·1 per cent), a mixture of salts (0·2 per cent), casein hydrolysate (2 per cent) and the above-mentioned vitamin B complex (but with only 7·5 γ biotin per ml.) plus ascorbic acid 150 γ per ml. Although development on this medium was relatively slow (eggs to viable adults in 25 days), it proved to be the most suitable for studying the nutritional requirements of all stages of *Culex molestus*. Thus in the absence of pantothenic acid, all other factors being present, there was no development beyond the first instar; in the absence of thiamin, riboflavin or pyridoxin, the larvæ die in the second instar; in the absence of folic acid the larvæ reach the fourth instar but never pupate. In the absence of niacin the whole developmental cycle lasts 42 days and the adults are viable. In the absence of biotin the cycle lasts 36 days, but the adults are not viable. Ascorbic acid is not essential for complete development of viable mosquitoes, but in its absence the cycle is prolonged to 29 days.

It is interesting to note that the viable females raised on sterile media were autogenous and laid eggs in the absence of any kind of nutrition. Full details will be published elsewhere.

I have to thank Prof. S. Adler for his advice and interest in this work.

Mosquitoes and Malaria

WITH reference to the recent article on the Ronald Ross Jubilee[1], it may be of interest to note that, in a paper read at a meeting of the Royal Scottish Geographical Society in April 1892, Dr. H. Martyn Clark, of Amritsar, remarked "that, as some insects carry the pollen of one plant to the flower of another, so mosquitos [*sic*] transplant the malarial germ to a suitable *nidus* by directly inoculating their victims with it"[2]. He further stated that "it will probably some day be ascertained that the mosquito fulfils a part in their [that is, the germs of malaria] transmission". As Ross met Manson in 1894, and Manson brought forward the mosquito theory in that year, Clark's adumbration seems to be worthy of recall.

CHEMISTRY RESEARCH BOARD

A REPORT of the Chemistry Research Board which prefaces the report of the Director of the Chemical Research Laboratory for the year 1946 covers the nine-year period January 1, 1938, to December 31, 1946*, and thus presents a summary of the more important developments since the publication of the second report of the Board, which covered the three years ending December 31, 1937. A fuller account is promised in a further report which is still in preparation.

Both the Board's report and that of the Director devote considerable space to discussion of the post-war plans for the work of the Laboratory. The Chemistry Research Board proposed that the work of the Laboratory should be concentrated on a few well-selected topics in the fields of coal tar, corrosion of metals, inorganic chemistry, high polymers and plastics, organic intermediates and microbiology. For the present, owing to limitations of space, it is proposed that microbiological studies should be concentrated on corrosion problems, and the Board recommends that throughout its work the Laboratory should pay special attention to the development of new techniques. To implement this programme, expenditure at the rate of £70,000 per annum will be required as well as non-recurrent expenditure on equipment estimated at £20,000; these proposals have been approved by the Committee of the Privy Council for Scientific and Industrial Research.

The Director of the Laboratory in his report details the objectives of the work of the five main research sections in which the scientific staff of twenty-five scientific officers, thirty-three experimental officers and assistants, and twenty-five laboratory assistants has been organised to implement these proposals. There are also two non-sectional groups for exploratory and special work under the Director and Assistant Director, respectively. The present objectives comprise the investigation of corrosion in immersed and atmospheric conditions with the view of the prevention of rusting, tarnishing and corrosion of ferrous and non-ferrous metals in industrial use; the investigation of the microbiological corrosion of metals, particularly in soil, by the influence of bacteria which reduce sulphates, and the investigation of *ad hoc* corrosion problems of industrial importance. In the inorganic field they include the investigation of semi-rare metals, especially their isolation from wastes and low-grade sources, the study and development of physical methods of analysis, and development of micro-analytical methods and other new techniques; in that of high polymers and plastics, the determination of the relations between structure and properties and the preparation of improved plastic materials such as glues and ion-exchange resins; and in the coal tar field, the isolation and identification of tar constituents using the newest methods of separation and analysis, determination of the physical and physico-chemical constants of tar constituents and derived or related substances, and the development of new uses for tar products and their derivatives. The programme also includes the study of high-pressure operations and the production of useful chemicals by such means, and the preparation of compounds capable of polymerization or co-polymerization, particularly those containin silicon.

The Board's report, as well as that of the Directo refers to some of the directions in which progress ha been made on these main items during 1946, and th latter report describes the new work done by th non-sectional groups in collaboration with th Agricultural Research Council on the formulation c salves or smears for control of ticks and in devisin a new micro method for the rapid determination o D.D.T. Satisfactory results have also been obtaine by this section in work on blow-fly control. In th Engineering Services, the Corrosion Section has redesigned the coupling used for the slow rotation o specimens so as to ensure positive and concentri alignment of the spindles to the shafts, and a sectione view of the arrangement is included in the repor Investigations of the corrosion-rate of mild steel i salt solution using the high-speed rotor suggest tha the nature of the surface finish may appreciabl influence corrosion-rates and the reproducibility o results.

The Corrosion of Metals Section has continued t develop both the high-speed and the low-speed roto techniques for immersed conditions, and with th former technique has investigated the influence o surface preparation on the reproducibility of corrosion-rate and the influence of movement on th corrosion-rate of mild steel in fresh water. Using th new endless belt and beaker type of apparatus fo accelerated atmospheric corrosion tests recently note (*Nature*, 162, 90; 1948) the corrosion of steel in sal water atmospheres and the effect of impact damag on the corrosion of painted steel have been examined In collaboration with the Light Division of th National Physical Laboratory, a light-reflexion mete utilizing the integrating sphere principle, has bee constructed, and in collaboration with the Britis Iron and Steel Research Association the corrosio behaviour of a comprehensive series of low allo steels is being investigated, using the oxyge absorption apparatus and the low-speed roto apparatus. An extensive search is being made fc organic corrosion inhibitors more efficient tha sodium benzoate. Other work has been concerne with wrapping materials and with vapour-phas inhibitors, as well as with the influence variou methods of surface treatment have on the corrosio resistance of mild steel and on the protection afforde by applied coatings.

In the Inorganic Section an attempt is being mad to correlate the rare metal content of flue dust an coal ash with that of the fuel from which the dust o ash originated; and methods of extraction o germanium and gallium from flue dust are bein studied. The physical chemistry group has give attention to detection and possible estimation c some minor metals by fluorescent technique; and i work on foams for fire fighting, carried out for th Ministry of Home Security, a portable foam mete has been designed which has been very useful i large-scale experiments with petrol fires.

The High Polymers and Plastics Section's comprehensive study of the mechanical properties c reinforced plastics, commenced, jointly with th Engineering Division of the National Physical Laboratory, during the War, has led to a clearer understanding of the relationships existing between th mechanical properties of laminated plastics and th properties of their components. In connexion wit the study of weathering properties, a more convenien pparatus is being constructed for the accurate etermination of the sorption isotherms of phenol-ormaldehyde resins, and the study of the relation etween structure and dielectric properties of high olymers is being resumed. A critical review has een made of the literature dealing with the ion-xchange properties of high polymers, and exploratory ork commenced on the 'Wofatits'. In the field of dhesives, work has been carried out to improve the tting of resins from monohydric phenols and also f rescorcinol-formaldehyde resins. A cold-setting sorcinol-formaldehyde glue S.R.38, developed in 944–45, has shown excellent strength and durability. study has also been made of glues for light alloys.

---

* Department of Scientific and Industrial Research. Report of the Chemistry Research Board for the Period 1938–1946, with Report of the Director of the Chemical Research Laboratory for the Year 1946. Pp. iv + 68. (London: H.M. Stationery Office, 1948.) 1*s*. 3*d*. net.

The Coal Tar Section has completed and brought to operation an all-metal semi-scale fractionating lumn and has used the column in the preparation f a tar-oil fraction containing the two methyl-aphthalenes. A high-vacuum pumping system has een set up to manipulate highly purified and ygroscopic materials. A new expression has been educed for the relationship between differential anges of composition with boiling-point and applied the quantitative calculations of the changes in mposition with temperature of the azeotrope rmed between ethyl acetate and ethyl alcohol. esults obtained in the separation of 2 : 6-butidine, picoline and γ-picoline by azeotropic distillation ith acetic acid are recapitulated in the report, and method worked out for the separation of crude ylole fractions has been applied to the examination a number of crudes of different origin. Some work as been done on the fractionation of lutidine bases, d a method of estimating acenaphthylene in enaphthene based on ultra-violet absorption spec-ography has been applied to the determination of e acenaphthylene content of the crude material rmed in the dehydrogenation of acenaphthene.

In the Organic Intermediates Section, preliminary ork on organic compounds from boron was not romising; the chief attention was therefore given the organic compounds from silicon, including the rect synthesis of methylchlorosilanes and their paration by fractional distillation and alcoholysis, d the preparation of organo-silica resins and astomers. Results obtained in the hydrogenation metallic salts of fatty acids indicate that lead salts ay prove superior to those of copper.

The report of the Chemistry Research Board itself fers to many of these investigations, which are scribed in somewhat greater detail in the Director's port. The former report also mentions the estab-hment, on the Board's recommendation, of a joint nel on acetylene chemistry, with the Director of e Laboratory as chairman, between the Department Scientific and Industrial Research and the Ministry Supply, to consider the present position of the search on and development and production of etylene in the United Kingdom and its utilization an intermediate product in chemical industry. he Board has also recommended the resumption of ork on the 'Oxo' reaction between olefins, carbon onoxide and hydrogen to yield aldehydes. Reference the work of the Laboratory during the war years very brief; but among its contributions to the war fort thus singled out for mention is the rotor test r assessing the relative value of a variety of pro-ctive coatings, the evaluation of anti-freeze aterials and the discovery of the inhibitive pro-rties of sodium benzoate, both as an addition to ueous solutions and when incorporated in wrapping materials. A long series of experiments in the Laboratory showed that suitable carbon blacks could be prepared from indigenous material, particularly coal tar products, and a highly successful foam for fighting petrol fires was also developed from indigenous sources. Much attention was given to the development of a food yeast from *Torula utilis* as an insurance against possible shortage of protein food, and on the basis of this war-time research and development, the Colonial Office has now erected a full-scale plant in Jamaica. The shortage of derris led the Laboratory to collaborate with the Agricultural Research Council in the development of products for the control of animal parasites, and a satisfactory D.D.T. emulsion was finally formulated for the control of blow-fly on sheep.

Lists of papers published from the Laboratory during 1946 and of British patents and patent applications granted or filed during the year are appended to the report.

A summary account of current work at the Laboratory was published in *Nature* of July 17, p. 90.

PRODUCTION OF INDOLE BY *ESCHERICHIA COLI*

By Dr. EDWIN A. DAWES

Department of Biochemistry, University of Leeds

THE mechanism of the production of indole by *Escherichia coli* has attracted the attention of many workers since Hopkins and Cole[1] first demonstrated that the precursor of indole is tryptophan. The problem is an intriguing one among the bacterial degradation of amino-acids, inasmuch as fission of a carbon–carbon bond occurs at a position in the molecule remote from the amino- and carboxyl-groups, instead of the more usual carbon–nitrogen split. It became even more intriguing when an exhaustive survey of theoretically possible intermediates in the reaction failed to give rise to indole in the presence of the organism.

In 1922, Frieber[2] described a series of growth experiments in which tryptophan in the growth medium was replaced by various indole derivatives, and he found that no indole was produced from 3-indolecarboxylic acid, 2 : 3-indoledicarboxylic acid, skatole, 3-indolealdehyde, 3-indoleacetic acid, β-3-indolepyruvic acid and β-3-indole-ethylamine. In spite of the failure of 3-indoleacetic acid to give rise to indole he postulated that the reaction occurred in two stages, namely: (1) formation of 3-indoleacetic acid; and (2) the breakdown of this compound to indole; only the former occurring in the presence of fermentable carbohydrate.

Harden[3], in 1930, gave the reaction as follows: Tryptophan → β-3-indolepropionic acid → 3-indoleacetic acid → indole.

Extensive work on this subject appeared in 1935 by Woods[4] who, using the washed viable cell suspension technique, demonstrated that five atoms of oxygen are required for the complete oxidation of one molecule of tryptophan, and that *D*-tryptophan is not metabolized; and he presented strong presumptive evidence for the anaerobic production of β-3-indolepropionic acid (cf. Hopkins and Cole[5]). He also investigated the action of cell suspensions of *Esch. coli* on various possible intermediates[6], and he was forced to reject Harden's hypothesis[3] and also that of Raistrick[7] based on analogy with histidine metabolism. Compounds tried included those used by Frieber[2] and also β-3-indoleacrylic acid, all of which gave no indole production. β-3-Indolepyruvic acid, but only in the presence of ammonia, gave 10 per cent production of indole, presumably due to tryptophan being first formed.

Again in 1935, Happold and Hoyle[8], simultaneously and independently, using non-viable cell suspensions, obtained similar results to Woods with the possible intermediates, and they gave the name 'tryptophanase' to the enzyme complex which is responsible for the reaction. They went on to show that in the presence of fermentable carbohydrate the failure to produce indole is presumably due to the non-production of the tryptophanase system[9]. This observation was afterwards verified by Evans, Handley and Happold[10], in reply to criticism by Fildes[11], and they later showed that complete inhibition of indole production only occurs in the presence of phenylalanine and tyrosine[12].

Meanwhile, Baker and Happold[13] had been concerned with the determination of essential structural conditions necessary for the reaction to occur. By systematically modifying the tryptophan molecule, it was shown that an intact side-chain is necessary for indole production, and (later) that the =NH group of the indole nucleus must be unsubstituted[14]. On the basis of this work, a tentative mechanism for the reaction was suggested involving reductive fission of an intact alanine side-chain.

However, in 1942, Krebs, Hafez and Eggleston[15] suggested that β-*o*-aminophenylacetaldehyde is the effective indole-producing intermediate. They assumed that oxidation of the tryptophan molecule yields β-*o*-aminophenylethanol, which then condenses spontaneously to form indole. This was not substantiated, and the Leeds workers[14] showed that with β-*o*-aminophenylethanol the best results represented only 22 per cent conversion to indole in 18 hours, whereas with tryptophan the yield was 90 per cent in less than 2 hours; furthermore, dimedon completely inhibited the former reaction but was without effect on the tryptophan–indole reaction.

The next hypothesis concerning the mechanism of the reaction was put forward by Tatum and Bonner[16] in 1944. From a study of the way in which a mutant strain of the mould *Neurospora crassa* synthesizes tryptophan from indole and serine, they postulated that the breakdown of tryptophan to indole by *Esch. coli* is a reversal of this reaction, that is, hydrolytic fission to yield indole and serine. In support of this, experiments were quoted in which inhibition of indole production is produced by the addition of serine to tryptophan in the presence of sterile washed suspensions of the organism, the effect being specific and a function of the concentration; the biosynthesis of tryptophan from indole and serine was also claimed. The biosynthesis of tryptophan by *Esch. coli* was not verified by Fildes[17] or the present author.

Since all the 3-indolyl derivatives tried failed to give rise to indole, the hypotheses of Baker and Happold[13] and Tatum and Bonner[16] involving fission of the intact side-chain, as alanine and serine respectively, were eminently attractive. Dawes, Dawson and Happold[18] conducted an analytical investigation of the reaction employing paper chromatography, and making use of Dawson's[19] observations of the effect of 'Mepacrine' on the tryptophanase activity of *Esch. coli*. Dawson showed that under the influence of 'Mepacrine' there is no oxygen uptake by washed cells over an initial 6 minutes while indole is produced in reduced amount The possibility of oxidation of any intermediate i these circumstances is much reduced, and under suc conditions alanine was detected whereas serine wa never found, thus strengthening Baker and Happold' hypothesis. Attempts to produce alanine by chemica reductive fission of tryptophan using Raney nicke catalyst failed, although indole was produced. Thi may not be due to true reductive fission but rathe the catalytic effect of a heavy metal on tryptopha as in Herzfeld's[20] experiments, and more recently i the work of Kuiken, Lyman and Hale[21].

The inhibitory action of serine on indole formatio was shown to depend on the degree of saturation o tryptophanase with tryptophan, and to be not simpl a function of concentration; while the possibility o a phosphoclastic fission occurring to yield indole an serinephosphoric acid was examined by pape chromatography and rejected.

Dawes, Dawson and Happold[22] obtained th enzyme in the cell-free state and investigated th action of various recognized inhibitors[23,24] on it. I this way evidence was obtained for the presence o carbonyl and iron-containing components, whil spectrophotometric analysis furnished evidence of nicotinamide system; iron was detected by spectrochemical analysis. The enzyme could be resolved b dialysis, and riboflavin was shown to be present i both apoenzyme and dialysate by microbiologica assay. Reactivation of the apoenzyme was achieve with pyridoxal phosphate, riboflavin and diphosphopyridine nucleotide. Crude enzyme extracts performed the reaction with consumption of five atom of oxygen, but the partially purified enzyme produce indole anaerobically as recorded by Wood *et al.*[25] Such samples required only pyridoxal phosphate a coenzyme, and hence riboflavin and diphospho pyridine nucleotide appear to be concerned in th further oxidation of the pyruvic acid first formed purification removes the enzyme(s) concerned in this

However, that alanine is not the normal inte mediate in indole production was shown by Wood Gunsalus and Umbreit[25], who partially purified th enzyme by ammonium sulphate fractionation an found that it was then resolved and could be re activated by pyridoxal phosphate. This enzym would not deaminate alanine or serine, while sti producing indole from tryptophan, and hence neith could be intermediates in the reaction; the produc of the reaction are one mole each of indole, pyruvi acid and ammonia, and no oxygen is taken up in th process.

It seems a pity that Wood *et al.* call the enzym which effects the fission 'tryptophanase', when th term was originally used to connote the complex pe forming the complete oxidation. An iron-containin system appears to function in the overall oxidatio reaction, and it is significant that verdoperoxida and cytochrome *c* both stimulate indole productio

The Michaelis constant of tryptophanase is give as $2\cdot5 \times 10^{-5}$ by Wood *et al.*, but they state that t half maximum reaction-rate is obtained with 35 μg tryptophan per ml. and this gives a K_M value 1·7 × 10^{-4} and is more in accord with the autho figure of $4\cdot1 \times 10^{-4}$.

The fact that indole is formed anaerobically rais interesting speculation on the claims of Hopkins an Cole and Woods that β-3-indolepropionic acid produced in anaerobic culture; strain differences ma well account for this. However, the search for inte ediates in the reaction has now been cleared up by Vood *et al.*, although α-aminoacrylic acid may be he primary fission product (this would decompose pontaneously to pyruvic acid and ammonia in queous medium), and the reaction is a balanced one om the oxido-reduction point of view. The detection f alanine in the presence of 'Mepacrine' may be due a diversion of the normal reaction path, such as ydrogenation of α-aminoacrylic acid, or to reaminaon of the pyruvic acid product.

EXCITATION PROCESSES IN MOLECULAR NITROGEN

By R. W. NICHOLLS

Imperial College of Science and Technology, London

N controlled electron experiments it has been usually assumed[1] that in the emission of the triplet nds of molecular nitrogen, transitions to the upper vels of the band systems concerned come about rectly as a result of collisions of the first kind beeen molecules in the ground-state $X^1\Sigma_g^+$ and fast ctrons. A further assumption made is that the ergy values of the upper states of the bands ncerned are the voltages at which they respectively pear when excited by an electron beam of conlled energy. These assumptions lead to the placing the triplet-levels approximately 2 volts higher an the normally accepted values based on reliable ectroscopic evidence[2]. In particular, the $A^3\Sigma_u^+$-el would be placed about 2 volts above the value gested by the analysis of the Vegard – Kaplan nds $A^3\Sigma_u^+ \rightarrow X^1\Sigma_g^+$.

The results of these experiments[1], which are reasonly consistent, are summarized in the table on p. 232. It would seem, therefore, that the assumptions mentioned are in error. This view is further strengthened by the following facts.

(1) Only singlet systems are obtained in absorption experiments in nitrogen, namely, the Lyman – Birge – Hopfield and Birge – Hopfield bands. The triplet bands do not appear in absorption, and consequently as electron and photon collisions with molecules generally result in the same excitation, it would be expected that electron collisions with ground-state molecules would excite the singlet- rather than the triplet-levels.

(2) The multiplicity change (singlet-triplet) involved in direct excitation of the triplet-levels from the singlet ground-state makes such a transition forbidden, and therefore a relatively rare event, both in the case of electron collisions and of photon collisions.

It is the purpose of this note to suggest a more probable excitation process which accounts for the observed experimental results without incurring an artificial raising of the triplet-levels, and which violates neither the selection rules nor the Franck – Condon principle.

It is suggested that primary excitation by collisions between ground-state molecules and electrons results in the population of the singlet-levels: $a^1\Pi$ and b. b^3 is a group of eight levels between 12·5 and 14 volts (the upper states of the Birge – Hopfield and Gaydon bands), which for the purposes of this discussion may be considered together. By analogy with the atomic case[4], we expect the excitation probability function of a level for non-intercombination (singlet-singlet) transitions to rise from zero at the energy of the level in question to a broad maximum somewhat above it. A singlet-level will therefore be most populated when the exciting electrons have the energy corresponding to this maximum. Population of the triplet-levels can then come about by intercombination collisions of the second kind between slow electrons and the molecules in the excited singlet-states. For such second-kind collisions to be effective, two considerations have to be taken into account: (1) The balance between the life-time of a molecule in an excited state and the collision frequency of slow electrons. This is governed by excitation conditions and depends greatly on pressure. (2) The balance between the transition probability and the probability that, on collisions between an excited molecule and a slow electron, intercombination transitions of the second kind will occur. This is governed by molecular constants only.

An analysis which has been made of the excitation kinetics of this mechanism shows it to be more likely than the one previously assumed. Details of this analysis will be published shortly.

This mechanism was suggested primarily by a comparison of the energies of the singlet-levels with the electron energies at which the triplet bands appeared (see table). The appearance potential of the first positive bands, *after correction by extrapolation to the* (0,0) *band*, is approximately 9·5 volts, which is about the value for the maximum excitation probability of the $a^1\Pi$-level. The appearance potential of the second positive bands is approximately 13 volts, which again is very near the maximum probability of excitation of the b-levels. The fact that the first positive appears at approximately 9·5 volts on the excitation of the $a^1\Pi$-level, and that it is not fully developed until the second positive bands appear at approximately 13 volts, reaching a maximum with

	Energy-levels			Band systems	Appearance potentials (volts)	Remarks
	Singlets	Energy (volts)	Triplets			
N_2	$X^1\Sigma_g^+$ (ground-state)	0		$A^3\Sigma_u^+ \to X^1\Sigma_g^+$ Vegard – Kaplan		Forbidden transition
		6·2	$A^3\Sigma_u^+$			
		7·3	$B^3\Pi_g$	$B^3\Pi_g \to A^3\Sigma_u^+$ First positive	9·3 (S), 9·4 (V), 9·5 (D)	Fully developed on excitation of second positive, maximum intensity at ~ 15 volts
	$a^1\Pi_g$	8·5				
		11	$C^3\Pi_u$	$C^3\Pi_u \to B^3\Pi_g$ Second positive	12 (D), 13 (S), 13·16 (T, W), 13·4 (V)	Maximum intensity at ~15 volts
		12·8	$D^3\Sigma_u^+$	$D^3\Sigma_u^+ \to B^3\Pi_g$ Fourth positive	15 (D)	Maximum intensity at ~20 volts
	b (8 levels)	$\left\{\begin{matrix}12{\cdot}5\\14\end{matrix}\right.$				
N_2^+	Doublets			$B'^2\Sigma_u^+ \to X'^2\Sigma_g^+$ First negative	18 (D), 19 (S)	Maximum intensity at ~ 80 volts
	$X'^2\Sigma_g^+$	15·6				
	$B'^2\Sigma_u^+$	18·7				

(S), Sponer; (D), Duncan; (T, W), Thompson and Williams; (V), Vegard.

them, strongly suggests that the primary population of the B^3 -vibrational-levels, below the $a^1\Pi$-level, is due to collisions of the second kind between slow electrons and molecules in the $a^1\Pi$-state, while the secondary population of the $B^3\Pi$-levels, especially those which lie above the $a^1\Pi$-level, results from the emission of the second positive bands $C^3\Pi \to B^3\Pi$. A further factor contributing to the population of the $B^3\Pi$-levels, when b is excited, would be collisions of the second kind between slow electrons and molecules in the b-state. The fourth positive system $D^3\Sigma \to B^3\Pi$ appears at 15 volts when certain of the b-levels which lie above the $D^3\Sigma$-level become populated, and reaches a maximum intensity at approximately 20 volts. Owing to the metastability of the $A^3\Sigma$-level, numerous collisions of the second kind with slow electrons will be probable. A radiationless $A^3\Sigma \to X^1\Sigma$ transition will therefore be more likely than the emission of the Vegard – Kaplan bands in most usual forms of discharge in nitrogen. The first negative system $B'^2\Sigma \to X'^2\Sigma$ of N_2^+ will be excited directly by first-kind collision between ground-state $X^1\Sigma$ N_2 molecules and fast electrons.

The mechanism thus adequately accounts for the observed excitation potentials in terms of known levels of nitrogen. Further facts in its favour are:

(1) It is in accordance with the Franck – Condon principle in initial excitation.

(2) There is no change in multiplicity in the initial excitation.

(3) The recently proposed g symmetry of the $a^1\Pi$-level[5] renders that level metastable, thus raising the excitation life-time and making collisions of the second kind even more probable. Although the metastability tends to make the initial excitation less probable, the fact that the singlet bands appear in absorption shows that it can, and does, occur with a greater probability than the singlet-triplet excitation. The long path-length required for this absorption to occur provides experimental evidence for the met stability, as was pointed out by Herzberg[5].

The above ideas are a result of work attempting correlate spectroscopic and electrical observations a glow discharge in nitrogen. Should the suggeste mechanism prove to be correct, it may have a important bearing on auroral excitation, since man current theories of the aurora include direct single triplet excitation of neutral nitrogen, N_2, by electron

I should like to express my grateful thanks Dr. R. W. B. Pearse for valuable discussions on th subject.

INTERNATIONAL GEOLOGICAL CONGRESS

PREPARATIONS are now well advanced for t Eighteenth Session of the International Geologic Congress. So far about 1,500 geologists, representi some sixty countries, have registered as membe The programme of long excursions associated wi the Congress begins on August 7.

The Session will be formally inaugurated at meeting of the General Assembly in the Royal Albe Hall on August 25, when Mr. Herbert Morrison w welcome the delegates and members on behalf of t British Government, and Sir John Anderson, honora president of the General Organising Committee, w speak on behalf of that Committee. Prof. H. J Read, president of the Geological Society of Londo is president-designate of the Session.

During the following days there will be an extensive eries of sectional meetings, at which about two undred and fifty papers, of which only a few can e mentioned in this notice, and covering a very ide range of topics, are due to be presented.

In the Section on Problems of Geochemistry, uestions connected with the development and igration of magmas and the genesis of ore deposits, he geochemical history of single elements, and the rigin of serpentines will be discussed by distinguished ontributors, including Dr. N. L. Bowen of Washingon, Prof. H. von Eckermann of Stockholm, Prof. P. iggli of Zurich and Prof. W. Wahl of Helsingfors. n another petrological section, devoted to "Metaomatic Processes in Metamorphism", the 'magmasts' and the 'transformists' will present contrasting iews on the respective importance of magmatic and ydrothermal penetration and of solid diffusion in the rocess of granitization and of metamorphism in eneral. The contributors include Prof. P. Eskola of inland, Prof. N. H. Magnusson of Stockholm, Prof. . Wegmann of Neuchatel, Prof. H. G. Backlund of ppsala, and Prof. Ian Campbell of California.

Stratigraphical and palæontological problems will e discussed by several sections. The Section on hythm in Sedimentation will include papers by rof. R. C. Moore, Dr. H. R. Wanless, and other merican authors on cyclic sedimentation in the alæozoic Rocks of the United States, and by Prof. . F. Troedsson of Stockholm and other authors on hythm in the Mesozoic and Tertiary sediments of urope. Prof. A. Renier of Brussels, Dr. S. J. Dijkstra f Heerlen, Prof. Y. C. Sun of Peiping, Dr. J. J. orsky of Leningrad, and Dr. F. K. G. Mullereid of exico City are among contributors who will deal ith general and regional problems of facies corelation in the Section on Faunal and Floral Facies nd Zonal Correlation. The correlation of continental ertebrate-bearing rocks will be discussed in a eparate section, and the overseas contributors nclude Dr. C. Teixeira of Lisbon, Mlle. M. Richard f Algiers, Dr. R. A. Stirton of California and Prof. rik Stensiö of Stockholm. This Section will also old a joint meeting with the Section on the Pliocene–leistocene Boundary. The latter will attempt to each an agreed definition of the lower limit of the leistocene System by synthesis of the views of ecialist contributors, including Dr. L. S. B. Leakey f Kenya, Dr. A. Halicka of Warsaw, Dr. D. N. adia of India, Prof. van der Vlerk of Leyden, Prof. . Migliorini of Florence and Prof. C. Arambourg of aris. Another section will discuss the relation etween earth movements and organic evolution, nd includes papers by Drs. K. Zapletal and L. V. ěpek of Czechoslovakia, Academician V. A. Obruchev f Moscow, and Dr. A. Chavan of Nanterre.

An interesting field of inquiry is covered by the ection on the Geology of Sea and Ocean Floors. In is a number of American geologists will describe cent work on submarine geology of the Northern arshalls, including recent borings on Bikini Atoll; nd Prof. C. Francis-Bœuf of Paris will speak of the se of the 'Bathyscaphe-Piccard-Cosyns' in subarine studies. Other contributors are Prof. R. M. ield of Princeton, Prof. P. H. Kuenen of Groningen, nd Dr. J. S. Lee of Nanking.

Three sections are specifically devoted to applied eology. A symposium on the geology, paragenesis nd reserves of the ores of lead and zinc has been repared under the editorship of Dr. K. C. Dunham nd will be discussed by a special section. Its assessment of world reserves suggests that little more than about nineteen years production of lead ores and twenty-four years production of zinc ores can be foreseen. The Section on the Geological Results of Applied Geophysics will deal with recent magnetic, electrical, gravitational and seismic work on diverse problems in many countries. The Section on the Geology of Petroleum will include a wide range of papers on general and regional subjects, among which recent work in the oilfields of the Middle East is prominent.

There is also a section in which a great variety of miscellaneous papers will be presented. Among these, tectonic studies predominate, and the authors include Prof. A. Noe-Nygaard of Copenhagen, Prof. O. Holtedahl of Oslo, Prof. A. Demay of Paris, and Dr. A. Heim of Zurich.

The Association des Services Géologiques Africains will hold a series of open meetings at which a synthesis of research on African geology during the last decade will be attempted, and problems of correlation within the African continent will be discussed. The International Palæontological Union will also hold open meetings, including one specially devoted to the stratigraphical use of Foraminifera and another to the nomenclature of fossils. A series of special meetings on the mineralogy and geology of clays has been organised in conjunction with the Clay Minerals Group of the Mineralogical Society.

Three major items in the technical programme are special addresses on the structural history of Britain, by Sir Edward Bailey and Prof. O. T. Jones, who will respectively deal with Scotland and with England and Wales; and a colour film and lecture on the new Mexican volcano Paricutin, presented by Dr. F. H. Pough of the American Museum of Natural History.

During the period of the Session receptions will be given by H.M. Government, by the Geological Society of London, the University of London and a number of other authorities and institutions.

A series of ninety-six day and half-day excursions demonstrating the geology of south-eastern England will take place during the period August 20–September 4. After the closing meeting of the General Assembly on September 1, there will also be another series of seventeen long excursions covering practically the whole of Great Britain and Eastern Ireland.

CONDENSATION OF INTERSTELLAR MATERIAL INTO STARS

F. HOYLE has suggested (*Mon. Not. Roy. Astro. Soc.*, **107**, 4; 1948) a criterion for determining the degree of condensation of interstellar material into stars. Observational data for disk-shaped nebulæ, such as *M* 31 and *M* 33, suggest that only a small fraction of the total mass is in the form of stars, whereas Oort has found that the elliptical nebula NGC 3115 must be almost entirely composed of stars. The paper is devoted to a consideration of the factors that determine the fraction by mass of a nebula that is condensed into stars, and a new method for attacking this problem is developed which suggests that condensing stars with masses exceeding 0·2 that of the sun must become rotationally unstable before reaching the main sequence stage, and such stars must evolve by ejecting material until their masses are reduced below the critical value. Present available information suggests that the ejected material is thrown off to infinity, and hence stars forming in the main body of nebulæ such as *M* 31 or *M* 33 have masses less than 0·2 that of the sun at the time of condensation to the main series state; but the masses can afterwards increase by accretion of interstellar matter. The application of the criterion shows that we should expect both the nuclei of disk-shaped nebulæ and the elliptical nebulæ to be almost entirely condensed, but the main body of a disk-shaped nebula such as *M* 31 would be largely uncondensed. The highly condensed state of the nuclei of disk-shaped nebulæ and elliptical nebulæ receives an important application in determining the ages of the extragalactic nebulæ, and Hoyle shows that these are of the order 5×10^9 years.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Plant Pathologist (Scientific Officer Grade), and a Field Officer (Experimental Officer Grade), in connexion with potato storage investigations at the University of Nottingham, Sutton Bonington—The Secretary, Agricultural Research Council, 6a Dean's Yard, London, S.W.1 (August 14).

Charles Brotherton Scholarship and United Kingdom Gas Corporation Scholarships in the Department of Coal Gas and Fuel Industries with Metallurgy—The Registrar, The University, Leeds 2 (August 14).

Technical Assistant (Grade B) in the Botany Department, chiefly for mycological work—The Secretary and Registrar, University College of North Wales, Bangor (August 14).

Assistant Lecturer (Grade III) in Geology—The Secretary, The University, Edmund Street, Birmingham 3 (August 14).

Research Fellow to lead a research group engaged on work connected with the chemical constitution of coal, and two Research Workers—The Secretary, The University, Birmingham 3 (August 15).

Lecturers in (*a*) Physics, with subsidiary Mathematics, (*b*) Electrical and Mechanical Engineering, in the Ministry of Supply School of Electronics, Malvern—The Chief Superintendent, Telecommunications Research Establishment, Great Malvern, Worcs. (August 16).

Lecturer in Civil Engineering—The Registrar, The University, Leeds 2 (August 16).

Lecturer in the Department of Geology with special qualifications in Mineralogy and Petrology—The Registrar, The University, Manchester 13 (August 20).

Principal Scientific Officer to lead a team engaged in experimental and design work, involving problems of pilot plant for chemical engineering, heat transfer and development of special instrumentation and remote control methods, and Senior Scientific Officers for experimental and design work, involving similar problems, in the Engineering Division of the Atomic Energy Research Establishment, Harwell, Berks, under the Ministry of Supply—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W., quoting No. 2205 (August 26).

Lecturer (Grade IIc or IIb) in the Department of Chemical Engineering—The Secretary, The University, Edmund Street, Birmingham 3 (August 30).

Lecturer in Psychology in the University of Sydney—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W. 1 (August 31).

Demonstrators in Biology and Chemistry—The Secretary, Royal Veterinary College and Hospital, Royal College Street, London, N.W.1 (August 31).

Physicist to the Department of Radiotherapy—The Superintendent, Guy's Hospital, London, S.E.1 (August 31).

Senior Organic Chemist in the Biochemistry Section for work on the organic constituents of fruit-bearing plants—The Secretary, East Malling Research Station, East Malling, Maidstone, Kent (August 31).

Lecturer in Mathematics—The Registrar, University College, Southampton (September 4).

Lecturer or Assistant Lecturer in Mathematics, with special qualifications in Applied Mathematics—The Registrar, University College of Wales, Aberystwyth (September 4).

Tutorial Studentships in Electrical Engineering, and Organic Chemistry in the Department of Physiology—The Registrar, King's College, Strand, London, W.C.2 (September 13).

Director of Museums—The Town Clerk, City Chambers, Glasgow, W.2 (September 15).

Professor of Civil Engineering in Natal University College—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (September 15).

Mullard Readership in Electronics at the Imperial College of Science and Technology—The Academic Registrar, University of London, Senate House, London, W.C.1 (September 15).

Lecturer in Graphics and Machine Drawing, a Lecturer in Entomology, a Senior Lecturer in Organic Chemistry, and a Senior Lecturer in Inorganic Chemistry—The Registrar, Rhodes University College, Grahamstown, South Africa (September 15).

Senior Lecturer in the Department of Botany—The Registrar, The University, Manchester 13 (September 17).

Readership in Mathematics at Birkbeck College—The Academi Registrar, University of London, Senate House, London, W.C.1 (September 22).

Readership in Civil Engineering at King's College, Strand—Th Academic Registrar, University of London, Senate House, Londo W.C.1 (October 1).

Economic Botanist in the Department of Agriculture, Britis Guiana, to take charge of the Central Rice Station—The Director o Recruitment, Colonial Service, 15 Victoria Street, London, S.W.1.

Technician in Chemistry Department—The College of th Pharmaceutical Society, 17 Bloomsbury Square, London, W.C.1.

Ecologist in the Tsetse Control Department, Government o Uganda—The Director of Recruitment, Colonial Service, 15 Victori Street, London, S.W.1.

Controller of Agriculture in Cyrenaica—The War Office C.4(E), Room 447, Metropole Buildings, Northumberland Avenue London, W.C.2.

Entomologists for advisory and research work on crop pests and special research on the sisal weevil, on the staff of the Government o Tanganyika—The Director of Recruitment, Colonial Service, 1 Victoria Street, London, S.W.1.

Lighting Engineers, Heating and Ventilation Engineers, an Technical Research Officers, in the Factory Standards and Desig Branch of the Australian Department of Labour and National Servic —Mr. T. C. Graham, Australia House, Strand, London, W.C.2.

Game Ranger in Tanganyika, and a Game Warden in the Gol Coast—The Director of Recruitment, Colonial Service, 15 Victori Street, London, S.W.1.

Head of the College—The Clerk, National College of Rubbe Technology, Northern Polytechnic, Holloway Road, London, N.7.

Chief Computor in the Survey Department, Nigeria—Th Director of Recruitment, Colonial Service, Colonial Office, Sanctuar Buildings, Great Smith Street, London, S.W.1.

Lecturer in Mathematics in the University of Otago, Dunedin—The High Commissioner for New Zealand, 415 Strand, London, W.C.2

Senior Laboratory Steward (chemistry and biology)—Th Bursar, Merchant Taylors' School, Sandy Lodge, Northwood, Middx

Research Assistants (2, men or women) in the Department o Chemistry for work in physical-organic chemistry—The Professor Chemistry, Royal Holloway College, Englefield Green, Surrey.

Lecturer or an Assistant Lecturer in Geology—The Registrar The University, Nottingham.

Assistant Manager of the acid and ammonia works at Phoeni Wharf, East Greenwich—The Secretary, South Metropolitan Gas Co. 709 Old Kent Road, London, S.E.5, endorsed 'Assistant Manager—Chemical Works'.

SCIENCE AND ITS SOCIAL RELATIONS

THE resolutions adopted by the Committee on Science and its Social Relations of the International Council of Scientific Unions at its meeting in Paris during June 15–16, and which have been forwarded to the scientific press and to scientific institutions, reflect faithfully the trend of thought among a considerable body of scientific men throughout the world. The recent review of the work of the Rockefeller Foundation in 1947 by its president, Dr. Raymond B. Fosdick, gives witness to similar views. At this meeting, Dr. C. H. Desch was the only British representative, Prof. F. J. M. Stratton, who was chairman during 1937–48, having retired on appointment as deputy scientific adviser to the War Office. The resolutions were the outcome of extensive discussions on the method of working to be adopted by the Committee and on its future programme of work, and in this connexion the first resolution affirms the opinion of the Committee that the most urgent problems of the social relations of science are to-day, first, the dangers threatening science from the fact that research in large measure has become dependent on military sources and on industry for its financing, and secondly, the way in which the results of science are actually introduced into society.

Both these problems were emphasized by the Committee in the circular letter issued in October 1947, and the first is the subject of keen debate in the United States at the present time. While the extension of Government research is regarded with a measure of distrust, a couple of recent articles indicate like concern at the growing practice of using university laboratories for the conduct of research sponsored by industry, and urge that the support which industry gives to university research should not be tied to the financing of particular projects, beyond designating a broad general field of research. Mr. S. Tout condemns outright the arrangements announced in the *New York Times* last January between seven industrial firms and the University of Chicago in regard to atomic research as not in the public interest. He urges that universities and like institutions should discontinue research for private enterprise and limit themselves to research for the public benefit.

The position in this matter varies from one country to another, and there does not appear to be any reason for believing that in Great Britain there is at present any serious danger that the direction of academic research is being deflected by industrial endowment. Endowments, such as the research fellowships established by Imperial Chemical Industries, Ltd., or Turner and Newall, Ltd., are entirely free from such restrictions other than that the research is to be conducted in some specific branch of science. Any malaise in Britain is rather related to the dangers arising from the subvention of research from military sources to which the Committee on Science and its Social Relations directs attention in its third resolution. The Committee believes that the increasing influence of the military on scientific research will lead sooner or later through its secrecy restrictions to the abrogation of the traditional freedom of expression and of publication, and will result in directed research not planned primarily for the benefit of science and mankind but rather for its destruction.

While it is possible that the fears entertained on this point are exaggerated, it seems just as certain that the Atomic Energy Commission must concern itself with the social implications of atomic power; for it is on that matter that liberty and equalitarian democracy become incompatible. Dr. M. H. Stone, of the University of Chicago, pointed out last year in *Science* (**105**, 507; 1947) that the Commission would have to concern itself with many questions which fall within the domain of the social sciences, and that it is important that similar attention should be given to the social effects of many other innovations flowing from our laboratories. Dr. Fosdick, in the Rockefeller Foundation report referred to above, clearly had the same point in mind when, in discussing the unity of science, he referred to the way in which the activities of the Institute for the Unity of Science in New York, towards which the Foundation made a grant in 1947, included research which cuts across the traditional demarcation lines of specialized disciplines and departments, the utilization of new knowledge in logic, the study of meaning and how it is communicated, and research on the philosophical, psychological and sociological backgrounds of science.

More important, however, in this connexion is the stress which Dr. Fosdick lays elsewhere in his report on the dependence of the health of the intellectual life of the world upon the free and unhampered exchange of ideas and personnel between universities and research institutions in all countries. Achievement is usually the result of the sustained thinking of many minds driving toward a common goal in many countries. The creative spirit of man, Dr. Fosdick once more reminds us, cannot be localized or nationalized. Ideas are starved when they are fenced in behind frontiers, and barricaded research in the long run leads to intellectual stagnation.

This is why Dr. Fosdick considers that the heavy concentration in the United States of research in atomic physics is unfortunate. However necessary for the time being from the security point of view, from the point of view of the growth of knowledge the arrangement is unhealthy. All knowledge is so interlocked that we cannot control research on the destructive aspects of atomic energy without at the same time interfering with world-wide research on its beneficent possibilities. Those American men of science who suggested the postponement indefinitely of the industrial development of atomic power not only recognized the impracticability of separating the development of nuclear power for industry from the growth of atomic-bomb power, but also that in the harnessing of forces which might bring incalculable benefit to mankind, knowledge could be retarded through lack of the cross-fertilization brought about by the exchange of knowledge.

Dr. Fosdick observes further in this connexion that in the history of modern science no single country by itself has ever had the intellectual resources or the imagination to bring to full fruition all the pote tialities of a new idea, and he comments on t unfortunate growing isolation of the scientific work and scholars of Eastern Europe. The high level creative research of the distinguished mathematicia of the Soviet Union, her imaginative work in bi medicine cannot be maintained if the Soviet Gove ment prevents direct and intimate relations wi workers in these same fields in other parts of t world. Isolationism is a blight which saps t vitality of everything it seeks to preserve.

Set in this context, the statement issued in Gre Britain in July by the Atomic Scientists' Associati seems lamentably weak and compares poorly wi the report "Policy at the Crossroads" in which t U.S. State Department has recently summarized t efforts of the United States and other Governme during the last two years to secure the adoption of effective system for the control of atomic energ Undoubtedly it is clearer than it was in 1946 that t sources of disagreement between the major Pow are so deep that the institution and working of control scheme are much more difficult than at fi supposed, and that there is little chance of agreeme at the moment on the lines of the Lilienthal propos or on any more limited scheme. The United Stat Government is naturally enough unwilling to aband its lead in atomic weapons without a comple system of inspection and control which would ensu that no other country was building up such arn ments to use against America. On the other har the Soviet Union believes that in any control authori acceptable to the United States, the countries voti with the U.S.S.R. would be in a minority and th the development of atomic energy in the U.S.S. would pass under foreign direction. The attitude Soviet Russia may also be determined by the vi that any complete scheme of inspection would gi the outside world information of strategic va about the location of their industry.

While, therefore, a substantial change in int national relations is necessary before any such pla can be revived with any hope of success, the Coun of the Atomic Scientists' Association quite righ records its continuing belief that some form international control is the most desirable ultima solution of the problem of atomic weapons. T Council believes that the solution can now be soug only through the constant promotion of all measu designed to make war less likely, and to reach settlement between East and West. In its anxie to avoid taking sides, however, the Council of t Association has become vague. The commenda attempt to avoid political bias is carried too far wh it avoids passing judgment on the facts. It is scarc an act of partisanship to point out that the man science in the modern totalitarian State is essentia a servant of the State, and that it is treason, as inde the law promulgated last year in the U.S.S. illustrates, for him to divulge any knowledge wh ever, save as the State allows. The Association d less than justice to the respect of British and Americ scientific workers for the full tradition of scient freedom, or to their freely expressed impatience very restriction imposed on them in the name of ecurity. No instinctive inhibitions will hamper British or American scientific workers in the exchange f scientific information; but it is at least arguable hat collaboration as suggested by the Atomic cientists' Association is more likely to promote, for he present, a one-way traffic to the disadvantage of he Western democracies. That is undoubtedly the eal reason why the American–Soviet Science Society as had to cease its efforts to promote the interchange f scientific ideas between American and Soviet ientific workers. If an improvement in political lations is a first condition of cultural intercourse, e Atomic Scientists' Association may well have jected a shade too cursorily the proposal for a oratorium in the development of atomic energy, or at a control scheme should be established of ose nations which were willing to submit to the sential inspection and other measures.

No one would pretend that such a partial control heme would eliminate the need for secrecy, though might limit the area, and it could not well intensify e suspicion which already exists between East nd West. What it could do is demonstrate the acticability of inter-nation control over an area in hich political conditions and relations gave the ntrol a chance to operate, and in this way it might ermit international control in the full sense to be hieved at an earlier date once the political situation the world as a whole had become favourable. The ommittee on Science and its Social Relations does ot touch on this specific problem; but in more eneral terms points out that the actual problems volved in all social relations of science are problems ncerning men's attitude to scientific knowledge and its application, in particular, to the power given by ience.

For this reason the Committee proposes to address self to a number of scientists, sociologists, persons rominent in educational work, and others to ascer-ain their opinions on the measure in which the ethods of international scientific work contribute the creation of an international spirit and to the aintenance of peace and on the ways in which ientific organisations and scientific men could tensify their activities for the maintenance of peace. his inquiry should be terminated before the end of eptember 1948, and the results will be presented to e secretariats of the United Nations Organisation d of its Educational, Scientific and Cultural rganisation as well as to the International Scientific nions. It appears from the memorandum that the ommittee contemplates investigations into these roblems with the help of psychology, the social iences, economics and juridical science as well as of e medical, agricultural and engineering sciences. particular, the Committee urges the United Nations ducational, Scientific and Cultural Organisation to omote the formation of international organisations presenting the medical and the engineering sciences. is true that the composition of the Committee on ience and its Social Relations gives it little authority speak for the engineering and medical sciences: en for the physical sciences its basis may well be regarded as altogether too narrow to be representative. If that limitation is kept in mind, the proceedings at its meeting last June demonstrate that the Committee should nevertheless prove of real value in indicating gaps in the field which need attention, and in stimulating thought about general and particular problems.

In both respects it can be claimed that the present memorandum merits careful consideration by the world of science, and as Dr. Lampitt recently remarked in Edinburgh, at the annual meeting of the Society of Chemical Industry, too little is known, in Great Britain even, of the work of the international unions. Besides its observations on the danger to science inherent in subvention from military science, the Committee elaborated the principles of a Charter for Scientists which deserve full discussion, and in particular from the point of view of their practicability in industrial as well as in Government employment. It also focuses attention on two other principal aspects of the social relations of science: the changes introduced in human societies through technological developments of science; and the antagonisms between biological order and social order.

In regard to the first of these, the Committee suggests for investigation as soon as possible, in addition to subjects already proposed by the secretariats of the Natural Sciences Section of the United Nations Educational, Scientific and Cultural Organisation, the effect on society of such developments as vitamins, new races of wheat and other food grains, artificial insemination, television, products derived from nylon, antibiotics, sulphonamides, etc., and the medical applications of artificial radioactive elements. As a first step, it is proposed to create two subcommittees to consider the formation of study groups to investigate the various items, and another subcommittee will be formed to organise meetings of specialists where the points of view of the biologist, the sociologist and the psychologist can be brought to bear on the explanation of antagonisms between human biology and society.

The Committee on Science and its Social Relations may thus be making a much more vital contribution to the development of international understanding than the Atomic Scientists Association or like bodies are able to do at the present time. It is, of course, important that there should be no duplication of effort, and that the limitations of what is practicable at the present time should be kept in mind. Fortunately, the memorandum from the Committee on Science and its Social Relations indicates that the Committee is anxious to work harmoniously with the International Council of Scientific Unions and the United Nations Educational, Scientific and Cultural Organisation, and that it only proposes independent action where gaps are clearly seen to exist, and then by agreement as to the means to be used. There can, therefore, only be welcome for this further declaration as to the dependence of scientific advance on full freedom of communication and discussion, and for the proposals to foster fresh opportunities for contact between creative minds at those borderlands of the sciences which have in the past proved so often their fertilizing and stimulating power in intellectual effort.

LAWS AND CONSTITUTIONS

The Federalist, or the New Constitution

By Alexander Hamilton, James Madison and John Jay. Pp. lxxi + 484. (Oxford: Basil Blackwell, 1948.) 9*s.* 6*d.* net.

A Fragment on Government and An Introduction to the Principles of Morals and Legislation

By Jeremy Bentham. Pp. lxvii + 435. (Oxford: Basil Blackwell, 1948.) 9*s.* 6*d.* net.

IN an interesting comment on "The Federalist", immediately after the publication in 1788 of the last of the essays of which it is composed, Washington wrote to Hamilton: "When the transient circumstances and fugitive performances which attended this crisis shall have disappeared, that work will merit the notice of posterity, because in it are candidly discussed the principles of freedom and the topics of government, which will always be interesting to mankind, so long as they shall be connected in civil society". With the rapid increase of American power in the past half-century, and the significant emphasis placed upon the 'American way of life' in current political agitations, it is important that some effort should be made to understand the influences that have shaped the growth of the great Republic, and "The Federalist" must always stand as a revealing commentary on the struggles of its early days. Here it is presented in the simple but attractive format of Blackwell's "Political Texts" series, with a valuable introduction by Max Beloff.

The work is essentially a practical contribution to the controversies that raged about the constitution of the new United States during 1787–88; but at the same time, as Washington's comment suggests, it is concerned with some of the fundamental problems of politics. While seeking to justify the constitution, it also provided, by inference, a cautious analysis of society and of society's instrument, the State. But the analysis of society is based upon a belief in natural rights that was characteristic of the age and that had already found expression in the challenging words of the Declaration of Independence. Government and law, it was held, had the limited task of preserving natural rights, and especially the rights of property: "As long as the reason of man continues fallible . . . different opinions will be formed. . . . The diversity in the faculties of men, from which the rights of property originate, is not less an insuperable obstacle to an uniformity of interests. The protection of those faculties is the first object of government. From the protection of different and unequal faculties of acquiring property, the possession of different degrees and kinds of property immediately results; and from the influence of these on the sentiments and views of the respective proprietors, ensues a division of the society into different interests and parties. . . . A landed interest, a manufacturing interest, a mercantile interest, a moneyed interest . . . grow up of necessity in civilized nations. . . . The regulation of these various and interfering interests forms the principal task of modern legislation."

It would be unwise to read into this more than it was meant to convey; but here, as elsewhere in "The Federalist", are to be found the origins of the differences over the interpretation of 'democracy' that to-day divide east and west. Many of the ideas of the work look back to Locke a century earlier; but the framers of the American constitution were able to go far beyond Locke in basing their new system on a fundamental, written constitution. To this fact is to be attributed much of the static quality and legalistic character of the constitutional development of th United States, modified though this has been, from Jefferson to Roosevelt, by new glosses. In short "The Federalist" is a valuable contribution to th study of contemporary history. The philosopher may condemn its limitations; but it has been described as "the finest study in the economic interpretation of politics which exists in any language", and, as Mr Beloff rightly points out, "a text which can still be argued about, is a text worth reading". It has moreover, acquired a new significance through the present discussions on "Western Union".

The American Declaration of Independence was issued in 1776, a year which proved to be somethin of an *annus mirabilis*, for it saw also the appearanc of two other works of lasting influence, namely, Adam Smith's "Wealth of Nations" and Bentham's "Fragment on Government", which was itself a commentary on yet another book of importance in the politica evolution of Britain and America, Blackstone' "Commentaries on the Laws of England" (1765). In the same year, too, Bentham was working on a introduction to a new penal code, which finall appeared in 1789 as "An Introduction to the Principles of Morals and Legislation". The "Fragment and "Principles", Bentham's earliest works, now appear together in a convenient volume, introduce in a clear and balanced survey by Mr. Wilfrid Harrison. The two works, Mr. Harrison claims, "occupy special place in political theory. They are the first major works in which a clear statement is given of the nature of government as an instrument the value o which is to be judged by its effects, and in which at th same time far-reaching claims are made in regard t the potential effectiveness of government." Earli philosophers who had written of the State as a huma rather than a divine institution had concerned themselves far more with the contractual obligation underlying it than with its actual working. Bentham like the authors of "The Federalist", turned to practical issues, and sought by a critical examination o the conduct of man in society to suggest the lines o improvement. His own copy of the "Fragment", a Mr. Harrison reminds us, was inscribed by him "This was the very first publication by which men a large were invited to break loose from the tramme of authority and ancestor-worship on the field o law"; while the very opening of the work link investigation ("discovery") with "reformation".

Bentham was thus typical of the best that his ag could produce, though his influence was not widel felt until the great period of reform that opened in th eighteen-twenties, towards the end of his long lif Whether, but for the French Revolution and th horror of change that it excited, he could hav achieved more at an earlier period cannot now b decided; but the influence of this typically eighteenth century thinker of the pre-industrial era is writ larg upon the history of Britain and British ideas in th nineteenth century. That influence flowed large from Bentham, the philosophical radical of the lat period. The interest of these earlier works lies part in the optimistic view of human nature which led hi later to declare of the period in which they we written that he "never suspected that the people i power were against reform; [he] supposed they onl wanted to know what was good in order to embrac it". Utilitarianism is now a largely discredited cree but its place in nineteenth century developmen nnot be ignored. Bentham's work, vast in quantity, s fragmentary and limited in scope; but his method critical thinking, as set out, for example, in the osing words of the "Fragment", was sound, and ith "The Federalist" in mind one may read with terest its application in the "Principles" to the eas of the Declaration of Independence. "With en, who are unanimous and hearty about *measures*", entham wrote, "nothing is so weak but may pass in e character of a *reason*." The remark, and the ethod, have lost none of their validity during the riod of nearly two centuries since these words were t down.

MAURICE BRUCE

BERKELEY: FATHER OF PLANT PATHOLOGY

ytopathological Classics, No. 8

bservations, Botanical and Physiological, on the otato Murrain. By M. J. Berkeley; together with lections from Berkeley's "Vegetable Pathology" ade by the Plant Pathology Committee of the ritish Mycological Society. Pp. 108. (East Lan- ng, Mich.: American Phytopathological Society, 48.) 1.50 dollars.

MODERN farmers and gardeners are now well acquainted with the possibilities of control of lant disease. Should a new trouble be found, it is sually only a matter of time before a palliative or medy is discovered. It is, therefore, somewhat ifficult for us to realize the state of passive acceptance crop 'blights' which prevailed a century ago. We n, however, give a far greater measure of apprecia- on than could be accorded by his contemporaries to e Rev. Miles Joseph Berkeley. He, more than any ther, established on a sure foundation the concep- on of plant disease caused by parasitic fungi.

It is true that fungi had been found growing on lants to their detriment before Berkeley's classic aper on the 'potato murrain' appeared. There was, owever, no clear indication whether they were the rimary cause, or a secondary effect, of the diseased ondition. Berkeley's full powers were called forth y his celebrated literary controversy with Dr. John indley, who stated the purely physiological view at the 'murrain' was due to disturbed water lations resulting from unusual climatic conditions.

is impossible not to feel reverence for the scholar- ip and erudition of Berkeley's paper. Now that it reprinted in this classic form, it can provide back- round for teacher and student, and still give spiration to the more specialized mycologist.

The selections from "Vegetable Pathology" made y the Plant Pathology Committee of the British ycological Society provoke rather a different note humility. The completeness of Berkeley's concep- on of disease as abnormal functioning of plants ads, as yet, no corresponding completeness in odern studies. We are, alas, only too well acquainted ith 'Congelatio, freezing' and 'Sphrigosis, rankness', ut know all too little about them. Should anyone k us the cause of 'Exostosis, hard excrescences nsisting of sound tissue', we can only say we know ey occur, and shake our heads about the cause. is not that we have been idle, for studies on virus, n mineral deficiencies and on some non-parasitic aladies have explained many of Berkeley's classified iseases. The science of genetics has elucidated still ore. The real shortcoming is that whereas Berkeley directed the attention of mankind to damage caused by parasitic fungi, and showed that it was amenable to control—he it was who suggested the use of sulphur and lime to Mr. Tucker—the science of plant pathology languished until twenty years ago. It then began to gather momentum, is now beginning to command the respect of practical growers, and should look forward to a brighter future.

JOHN GRAINGER

FROM RADIUM TO THE ATOMIC BOMB

Atomic Energy

By Dr. R. R. Nimmo. (Frontiers of Science Series.) Pp. 201. (London: Pilot Press, Ltd., 1947.) 9*s*. 6*d*.

THE 'Frontiers of Science' series, of which this is the first number, is stated to be "intended for the growing non-specialist public which wants to keep abreast of recent scientific developments and so keep pace with a changing world". Atomic energy is undoubtedly one such important scientific development, and the general editor of the series, Dr. A. C. B. Lovell, has chosen well in asking Dr. Nimmo to write an account of the progress made in nuclear physics from the discovery of radioactivity in 1896 to the release of the first atomic bomb in 1945. Dr. Nimmo was, during the Second World War, a member of the British team engaged on the atomic bomb project in the United States, and has since been working at the University of Birmingham on the construction of particle accelerators, so that he writes on his subject with considerable authority and knowledge. It is true that Dr. Nimmo divulges no secrets, nor gives any information that is not contained in the official Smyth Report; but he does not hesitate to read between the lines and to set down in detail all reasonable deductions that an expert in this field can make from the official information.

To those with a moderate knowledge of chemistry and physics the first half of the book can be recommended as an excellent introduction to modern atomic structure and as an account of modern experimental techniques. The second half of the book deals with nuclear fission, chain reactions, uranium piles, plutonium, the atomic bomb and atomic energy plants, and will be read with interest by all who have not access to, nor the time nor ability to wade through, the mass of uncorrelated information which has been published during the last few years.

The last chapter of the book, on atomic energy and the future, is naturally speculative, but the problems to be faced and overcome are clearly stated, and the difficulties in the way of rapid development of nuclear physics, such as considerations of military security and the delay in the declassification of fundamental data, are specifically mentioned. The author's attitude is well summed-up in the concluding sentence of the book, "The future is full of hope and promise, but only if we see to it that never again are these new powers used for killing and destruction".

The reviewer has two faults to find with this otherwise excellent book. One is that, though reference is made to the health hazards in atomic energy work, little or no reference is made to the great benefits of the use of radioactive tracers in medicine, agriculture and industry. The other is the unusual arrangement of type and size of page, which, with its long close lines, is very fatiguing to the reader.

S. WEINTROUB

UNIVERSITY EDUCATION IN NOTTINGHAM

By Prof. H. T. H. PIAGGIO

ON July 9, 1948, the King in Council conferred full university status upon University College, Nottingham, so that the efforts of more than seventy years were crowned with success. In 1875 Mr. Richard Enfield asked the Nottingham Corporation to erect buildings to accommodate the Cambridge University extension lectures then being delivered in the city, and to add a library and a chemical laboratory. An anonymous donor offered £10,000 for this purpose. The Corporation adopted the scheme in an improved form, to include also a natural history museum and provision for the teaching of several branches of science, which up to then had been carried on by the Mechanics' Institute. The foundation stone was laid in 1877, and the College opened in 1881. At first there were only four professors, the Rev. J. F. Blake (natural sciences), Dr. F. Clowes (chemistry and metallurgy), Dr. J. A. Fleming (physics, mathematics and mechanics), and the Rev. J. E. Symes (English), with four lecturers, two demonstrators, and fifteen part-time teachers of science. Dr. Fleming (later Sir Ambrose Fleming, the inventor of the thermionic valve) left after one year, and was succeeded by Mr. William Garnett. At first there was no principal; but Dr. Clowes acted in this capacity from 1887 until 1890, and Mr. Symes from 1890 until 1911, both in addition to their professorial duties. A professor of engineering was appointed in 1884. In the following year the College started to train teachers. In 1893 a new wing was opened for the engineering and technical students, designed by the versatile Dr. Frank Granger, who later became professor of classics and philosophy. In 1898, Mr. Ernest Weekley, afterwards well known for his books on philology, became professor of French, and Dr. F. S. Kipping, from whose researches on the organic compounds of silicon the new silicone plastic industry has developed, became professor of chemistry. The culmination of this period of development was the Charter of Incorporation (as a University College) conferred by the Privy Council in 1903.

After this, for some reason, there was a check to the development. Perhaps the splendid initiative of the Nottingham Corporation in founding the College led the citizens to think that there was no need for them to take an active interest. Certainly the neighbouring counties considered it purely a Nottingham affair, which was no responsibility of theirs. In 1911 it became evident to Mr. W. H. Heaton, who after many years as professor of physics and mathematics had been appointed principal, that if a great effort was not made, the College was likely to decline. He established professorships of mining, economics and commerce, geology and geography, and history, and in 1913 there were hopes of a full charter. But in 1914 came war, and for four years the College was nearly empty. In 1919 the ex-Service men returned in embarrassing numbers, and the buildings were greatly overcrowded. The site in Shakespeare Street had very little room for expansion. There was difficulty in obtaining staff, and the financial position gave cause for anxiety. At a time when the difficulties seemed almost insuperable, Alderman E. Huntsman directed the attention of Sir Jesse Boot (afterwards Lord Trent) to the good work done by the College; thus, for example, an evening student Mr. E. H. Barton, was able to become a professor o physics, a fellow of the Royal Society, and a recognized authority on acoustics. Sir Jesse's interes was aroused, and he allocated to the College a larg site with a setting of exceptional beauty above th lake in University Park. Since then the Colleg Council has acquired a good deal of adjacent land and is now in the happy position of having room fo as many lecture rooms, laboratories, and halls o residence as are likely to be required for very man years to come. The new buildings were opened b King George V in 1928; but for some years longe the Faculty of Applied Science remained in Shakespeare Street, Nottingham, which also remained th headquarters of the vigorous Adult Educatio Department set up in 1920 under Mr. (later Prof Robert Peers. This Department is one of the larges of its kind in Great Britain.

In 1930 Mr. Hugh Stewart became principal, an threw himself with great energy into preparing fo full university status. In particular he emphasize the importance of research. He pointed out th necessity of transforming the governing body to tak account of the fact that the College now served th whole of the East Midlands. Unfortunately, hi incessant labours caused his untimely death in 1934 After a year with Dr. Granger as acting-principal Mr. H. A. S. Wortley was appointed principal. H had gained an extensive knowledge of the needs o the area in his former capacity as professor o education, and his wide popularity enabled him t carry through changes which, though necessary, wer sometimes a break with local traditions. In 1938 h obtained the supplementary charter, which reconstituted the governing body on the lines suggeste by Principal Stewart. From 1939 until 1945 progres was again stopped by war. In 1945 the Universit College handed over the Shakespeare Street building and the responsibility for evening classes, and technical education to a new authority, the Nottinghan and District Technical College. In 1947 the Midlan Agricultural College became part of the Universit College. In the same year was set up an Institute c Education, which will co-ordinate education activities, including research, over a wide area.

It was anticipated that Principal Wortley's nex achievement would be the attainment of a fu charter; but worn out with the double burden the war years, during which he also acted as deput regional commissioner, his health collapsed, and h died suddenly in 1947. The arduous task of gatherin up, at short notice, the many tangled threads half-completed schemes was taken up by Prof. Peer who, as acting-principal, had the satisfaction reaching the goal towards which so many had strive for so long. He has also greatly strengthened th staff, made fuller provision for research, and draw up the degree regulations for the new universit Mr. B. L. Hallward, for many years fellow of Pete house, Cambridge, and at present headmaster Clifton College, will become the first vice-chancello The chancellor is Lord Trent, previously preside and chairman of the College Council. He is the so of the College's great benefactor.

The University will start with five faculties, art (including law, theology, music, economics and soci administration), education, pure science (includin pharmacy), applied science (mechanical, electric and civil engineering, mining and fuels) and agr culture (including horticulture). New professorship re being established, and new buildings erected. he number of students is now about three times hat in 1938–39, and applicants have to be refused or lack of room. Negotiations to consider how the University and the technical colleges of the area can o-operate are in progress.

In addition to all the usual academic subjects except medicine), the University will deal with ertain special branches in which it feels particularly trong. It will continue the biochemical studies of he late Prof. J. M. Gulland, but with a shift of mphasis from nucleic acids to heterocyclic organic ompounds of importance in chemotherapy. Pharmacy will continue to receive much attention, and will develop on the research side. Among other strong points are magnetism, mycology (with a raduate diploma), ecology and parasitology of reshwater fishes, soil mechanics, statistical methods, own planning, and Biblical and related studies. The East Midlands is an important mining area, and the University is dealing with the related geological problems, and with mine ventilation. Experiments n new methods of mine illumination are expected to ontribute to the health and amenities of the workers t the coal face.

A Board of Local Studies has been set up. Con-ributions have already been made to Roman-British rchæology, the history of the Civil War (which started in Nottingham) and of other national events with a local setting, also of economic conditions in he eighteenth and nineteenth century, particularly of the lace and hosiery trade. A valuable source of information about medieval social and economic conditions is now available in the University library, in which Lord Middleton and Mrs. Percy Clifton, representing two families which go back for many centuries, have deposited their family records. Economic conditions of our own time will be studied by the rapidly increasing Department of Economics and Social Study, which is now to be subdivided. We look forward with confidence to the contribution he University will make to the East Midlands, to he nation, and to the international fraternity of learning.

ENZYMATIC CONTROL OF CELL DIVISION IN MICRO-ORGANISMS*

By Dr. WALTER J. NICKERSON
(John Simon Guggenheim Memorial Fellow)
Laboratorium voor Microbiologie, Delft

FROM lines of evidence converging from apparently widely separated fields it now appears possible to assemble evidence indicating that cell division in micro-organisms, and probably also in other organ-sms, is under the control of a unit enzymatic mechanism. The lines of investigation, developed quite independently, forming the foundations for this thesis are: (1) physico-chemical studies by Hinshelwood and co-workers[1] on the kinetics of bacterial growth and the state of balance between division and elongation; (2) the studies of Witkin[2] (genetic), Eisenstark and Clark[3] (electron microscope), and others[20,21,22] on irradiated bacteria; (3) cytochemical investigations of Pratt and Dufrenoy[4] on the mode of action of penicillin; (4) metabolic studies on dimorphic pathogenic fungi by Nickerson and Edwards[5]; and (5) examination of the chemical control of morphogenesis in yeasts by Jillson and Nickerson[6], the common denominator in all of these lines of investigation being a close examination of the effects of inimical or critical conditions on the morphogenesis of dividing cells. The examinations have revealed a common fundamental attribute of cell division of micro-organisms.

This fundamental attribute may be expressed by the use of a simple notation. Bacteria (B) may be induced to elongate into filaments (F) by various treatments which inhibit cell division but which do not simultaneously inhibit growth. The process itself may be denoted as a $B \rightarrow F$ conversion. Likewise with yeasts (Y), it is possible both to induce elongation into mycelia (M) structures through inhibition of cell division, and to inhibit the process in yeasts that normally show $Y \rightarrow M$ conversions as a characteristic feature. There are, furthermore, fungi which can be interconverted from a mycelial to a yeast form by changes in temperature alone, and for these it seems permissible to write $Y \rightleftharpoons M$ as an expression of the phenomenon. In the three cases the normal division mechanism by which micro-organisms maintain a single-cell condition may be inhibited without the simultaneous inhibition of other metabolic processes, thus permitting the organism to grow, unchecked, as a filament. Other common properties of the $B \rightarrow F$ and $Y \rightarrow M$ processes, as will be shown, permit the assumption that a comparable mechanism is being affected in the three cases.

Hinshelwood has developed a very convenient concept with respect to the change $B \rightarrow F$ from his studies on the action of proflavine, *m*-cresol, and of the effect of the nitrogen source on bacterial growth. Normal growth is viewed as the result of a balance between a division (D) factor and an elongation (L) factor; the latter factor has been shown to be diffusible. This diffusibility of the elongation factor L was recorded from the property of culture filtrates from *Bact. lactis aerogenes* of hastening the onset of growth, through a shortening of the lag period, when added to culture media; in some instances division did not keep pace, and the process $B \rightarrow F$ resulted. Other methods for disturbing the balance between the division and elongation factors included the incorporation into a nutrient medium of traces of *m*-cresol or proflavine; these agents selectively inhibited division without exerting marked suppressive action on other cell functions, with the result that cultures of *Bact. lactis aerogenes* so treated consisted of tangled masses of long thread-like elements.

While the appearance of the $B \rightarrow F$ phenomena is not markedly apparent with most bacteria in ordinary culture media, the production of the $Y \rightarrow M$ process and the occurrence of $Y \rightleftharpoons M$ among several of the pathogenic fungi are essential characteristics of their identification. It will be well to present at once the reasons for believing that the growth of yeasts by budding and of bacteria by fission may be accomplished in a comparable fashion despite apparent morphological differences between the two modes of growth. At least three rather convincing reasons may be advanced for this view. (1) Budding of yeasts has been shown[37] to exhibit the same mechanical principle (Principle of Least Action) characterizing the growth of other cells with determinate axes (*inter alia*, rod-shaped bacteria), for a yeast bud arises so that its long axis is a tangent to the mother cell at the point of contact. (2) There are genera of yeasts, for example, *Saccaromycodes*, which reproduce by fission, as do bacteria, but which are ostensibly related to other yeasts. (3) As will be shown, certain substances in trace concentrations promote the process $B \rightarrow F$ (and, furthermore, the promotion of $B \rightarrow F$ in Gram-positive bacteria is accompanied by a loss of Gram-positivity); these same substances, in trace concentrations, promote the process $Y \rightarrow M$ and loss of Gram-positivity in yeasts. Having set forth seemingly valid reasons for believing that the division of yeasts and of bacteria result from the action of closely comparable mechanisms, we may proceed with further comparisons.

---

* Based on a lecture given at the London School of Hygiene and Tropical Medicine on March 22, 1948.

Among the yeasts, the order Mycotoruloideæ is characterized by the formation of mycelial structures; three genera, *Candida*, *Trichosporon* and *Brettanomyces*, are included in the group. Experimental work pertinent to the discussion has been carried out mainly with species of *Candida*. In this genus there is one species, *C. albicans*, undoubtedly pathogenic for man and experimental animals, together with species of probable pathogenicity, and others that are non-pathogenic. All species exhibit the process $Y \rightarrow M$ under appropriate conditions. *C. albicans* may cause infections of various tissues, including chronic infections of the skin and nails. These latter regions may also be infected by other pathogenic fungi, the dermatophytes; now it is a clinical fact that mixed fungus infections of the skin or nails are rarely encountered. With isolates of *C. albicans* and the dermatophyte, *Trichophyton rubrum*, obtained from nail infections, Jillson and Nickerson[6] attempted to learn if the growth of one fungus could inhibit the growth of the other in culture and thus contribute an explanation for the known clinical situation. Such was, indeed, found to be probable. But the inhibitory effect exerted on *C. albicans* by *T. rubrum* was of a differential type; only the development of mycelial structure, *M*, was inhibited, whereas growth in the yeast phase, *Y*, was not appreciably affected. This *T. rubrum* effect was obtained first in two-membered pure cultures, and later shown to result from the production of two diffusible metabolic products, which have been partially characterized. Recently it has been found that activity in one of the fractions is probably the result of its —SH group content.

Early in the study of the effects of penicillin action on micro-organisms, it was found by Gardner[7] that sub-bacteriostatic concentrations of penicillin induced $B \rightarrow F$ conversions in Gram-negative as well as in Gram-positive bacteria. More recently, the cytochemical investigations of Pratt and Dufrenoy[4] have amply confirmed this point and demonstrated that Gram-positive bacteria become Gram-negative in the process. The latter authors have also made it clear that the probable mode of action of penicillin against Gram-negative organisms is the same as against Gram-positive organisms, in spite of the higher concentrations needed to achieve effects against the Gram-negative group. A very significant point emerging from these researches[4] is the implication of —SH group oxidation with the mode of action of penicillin. In plate inhibition-zone studies with *Staphylococcus aureus*, positive tests for —SH groups were always obtained with cells in the uninhibited regions, but were never obtained in the inhibited zone. The fact that loss of stainability of the Gram-positive complex accompanied the $B \rightarrow F$ process, resultin from penicillin action, also implicates —SH grou oxidation, since Henry and Stacey's[8] investigation on the chemical nature of the Gram-positive comple have shown it to be magnesium ribonucleate wit associated —SH groups; oxidation to S—S abolishe the stainability of the complex. Pratt and Dufreno have expressed the view[4] that penicillin exerts i bacteriostatic effect by promoting the oxidation —SH to S—S, and Cavallito[9] has shown that cystei can suppress the action of penicillin, presumably b acting as an —SH donor.

The probability that —SH groups represent th active component of one of the *T. rubrum* filtra factors effecting a suppression of the $Y \rightarrow M$ proces may be taken as further evidence of the similarity cell division processes in bacteria and in yeast Similarity in the action of cobalt on penicilli inhibition and on the $Y \rightarrow M$ process further link —SH groups in the two processes. Pratt an Dufrenoy[4] have noted that trace amounts of th cobalt ion Co^{++} increase the sensitivity of micr organisms to penicillin inhibition. It seems possib that the effect of cobalt lies in its ability to for complexes with cysteine, as shown by the work Michaelis[10]. In studies on the toxicity of cobalt t yeasts[11], a very sharp break appeared in the curve c growth *v.* concentration of cobalt ion in the region c $M/10,000$ Co^{++}. Employing radioactive Co^{56+58}, was found[11] that most of the activity accumulated i growing yeast cells in one distinct fraction. Th activity was retained in the cells during prolonge washing and during ether-acetone extraction, bu was removed by cold 10 per cent trichloracetic aci extraction. The Co^{56+58} was precipitable from thi extract on standing, after neutralization, as a ligh brownish flocculant. Work on the type of bindin for the cobalt in this fraction is in progress. Th addition of Co^{++} to media, in amounts insufficient t inhibit growth, favours the development of $Y \rightarrow$ process in yeasts ordinarily existing only in a *Y* for on agar media. *Hansenula anomala* has been pa ticularly examined in this connexion[12,13]. It develop much elongated cells, which tend to remain attache to give an appearance suggesting 'trees', on a mal agar medium with added cobalt ions. Cystei antagonizes the cobalt ion effect.

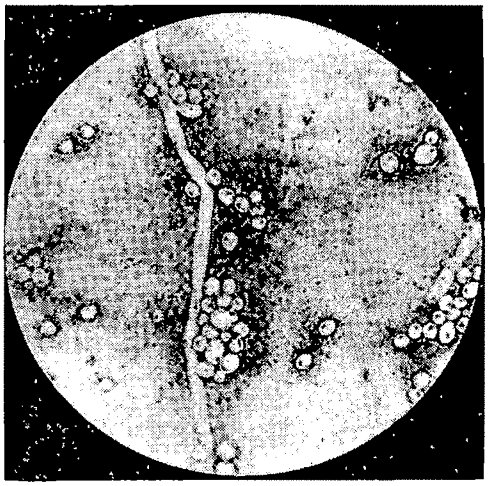

Fig. 1. *Candida albicans* from untreated slide culture on potato agar showing normal production of *Y*- and *M*-forms. Stained with 1 per cent aqueous toluidine blue; distinct nucleus in each *Y*-cell; three nuclei may be discerned along the length of the *M* filament. × 750

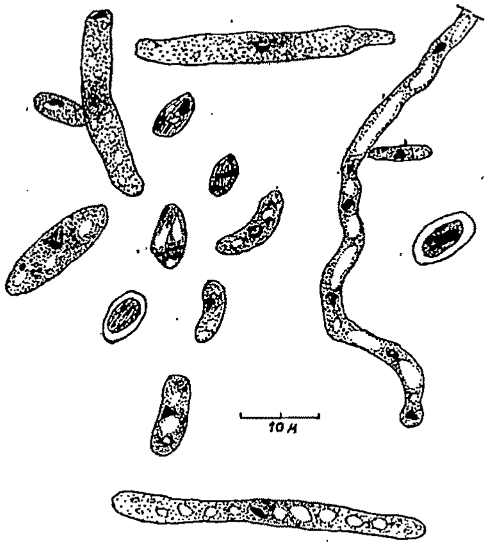

Fig. 2. *Trichosporon capitatum* from potato agar slide culture with penicillin (10 O.U./ml.). Toluidine blue staining. Production of two types of *Y*-cells (arthrospores and blastospores) is characteristic of this yeast. Nuclei were spaced at more or less regular intervals for more than 100 μ along the partially drawn *M*-filament

The implication of the —SH group of cysteine in he division processes of bacteria and of yeasts recalls he earlier work of Voegtlin and Chalkley[14] on *mœba proteus*, of Hammett[15] on *Paramecium*, and f Brachet[16] on the embryonic development of mphibia. In all this work, a relationship between —SH groups and cell division was strongly indicated. Vith *Amœba* it appeared[14] that glutathione enhanced he rate of nuclear growth (while cupric ions impeded t), thus speeding cell division, since division occurred egularly at an almost constant nuclear volume. In he experiments of Chalkley and Daniel[17] on *Amœba*, t was found that on the failure of fission processes experimentally induced) to result in cell division, here remained no 'residual tendency' towards ivision; the cell was left with two nuclei. Division f one of these was necessary before cell division ould again occur. In a general way, this relationhip holds with yeasts for $Y \rightarrow M$ processes. Excemely long filaments may be observed with only ne or a few nuclei scattered along the length of the *I* growth. With *Candida albicans*, which produces lusters of blastospores (uninucleate *Y* cells) at loci paced along an *M* axis (see Fig. 1), we may have an xample wherein division of an *M*-nucleus results, ot in division of the already formed filament, but intensive localized budding of yeast cells. In other nstances (Fig. 2) *M*-elements may be seen with umerous nuclei scattered along the filament. In he $Y \rightarrow M$ process it appears that the normal close ssociation between nuclear and cell division is isrupted so that growth occurs without cell ivision, while nuclear division may or may not ccur.

In the experiments of Hinshelwood on bacteria and f Nickerson *et al.* on yeasts, a very large proportion of the cells exposed to the various division-inhibiting substances were found to have entered an elongated state. Normally, with *C. albicans*, one may observe mycelia production around the entire border of a colony. The very high proportion of cells exhibiting an inhibited division, but uninhibited growth (defined as an irreversible increase in volume, following Went and Thimann[18]), seems to preclude the operation of mutational or survival-selection mechanisms as the basis for the observed phenomena. This is strengthened by the reversible nature of the processes, since filament or mycelial stages may readily give rise to bacterial or yeast forms of growth following the removal of the active chemical agents and transfer to suitable growth media. It seems permissible to regard the inhibition of division as the inhibition of an enzymatic mechanism, which may resume functioning when the inhibiting agents are removed. The effectiveness of proflavine, *m*-cresol, cysteine, and cobalt in trace concentrations against the division mechanism of growing cells favours an enzyme-inhibition concept. The specificity of these substances for the division mechanism of growing cells favours a unit enzyme-inhibition concept.

The argument in favour of a unit enzymatic division mechanism in cells of micro-organisms based on the specific response of cells to trace concentrations of proflavine, *m*-cresol, cobalt, and cysteine may be even more forcefully presented in the case of penicillin. Penicillin, as Dubos[19] has emphasized, does not act as a generalized, non-specific protoplasmic poison; its effectiveness in high dilution favours the concept of attack on specific loci of the cell. Much evidence now points to the action of sodium-penicillin G as operating through a shift toward the right in the —SH $\rightleftharpoons$ S—S functions of the cells; as has been noted, cysteine (—SH) suppresses the action of penicillin. The action of penicillin *in sub-bacteriostatic concentrations* in promoting the process $B \rightarrow F$ is one of the first detectable effects of penicillin. This specificity at extreme dilution is significant. The parallel (see Table) between the general phenomena of the processes of filament formation in bacteria, mycelium formation in yeasts, and penicillin action indicates a common specific functional unit as the sensitive locus in the cell.

Such a unitary enzyme concept is supported by genetic studies on irradiated bacteria (Witkin[2], Lea[20]), and by electron microscope studies of irradiated bacteria (Eisenstark and Clark[3]). Following ionizing radiation of bacterial cultures, Kempster[21] early observed that cells might fail to divide but retained the power of growth since elongated filaments were produced. Haberman and Ellsworth[22] have produced elongated cocci by such procedures, and Witkin[2] obtained greatly elongated cells of *Esch. coli*. The elongations following radiation have generally been observed to be irreversible.

Witkin, employing X-radiation, has obtained permanent $B \rightarrow F$ conversions; her analysis of the dosage-response data indicates a 'one hit–one gene' inactivation. Examination of filaments of *Esch. coli* (X-ray induced) in the electron microscope by

Agents uncoupling cell-division from cell-growth

Compound	$B \rightarrow F$	$Y \rightarrow M$	Gram positivity	Ribonuclease action
Proflavine	promoted[1]	promoted[13]	abolished[13,31]	inhibited[30]
Cobalt	promoted[4,11]	promoted[12]	abolished[12]	
Cysteine	prevented[4,11]	prevented[12]	preserved[12]	
Penicillin	promoted[4,7]	promoted[12]	abolished[4]	inhibited[33]

Eisenstark and Clark revealed 'breaks' spaced periodically along the length of a filament; they put forward the hypothesis that an "enzyme responsible for pinching off the cell wall in normal bacterial fission has been destroyed by rays while other enzyme systems continue to function".

With the group of pathogenic fungi exhibiting the process $M \rightleftharpoons Y$, depending on the temperature of incubation, it has recently been shown by Levine and Ordal[23] and by Nickerson and Edwards[5] that the interconversion of form is solely a function of temperature. The $M \rightleftharpoons Y$ transformations in *Blastomyces dermatitidis* and *B. brasiliensis* are obtainable without difficulty on a simple nutrient medium (consisting of ammonium-nitrogen, inorganic salts and glucose) just as they are obtained on complex media. No growth-factor requirements have been observed for either species of *Blastomyces*, nor have special atmospheric requirements been found to be necessary for the process $M \rightleftharpoons Y$. Since no chemical agent need be added to the cultures to promote the morphogenetic transformations, it seems that effects of temperature on the metabolism of these organisms may be examined more closely for possible clues to its action in the regulation of morphogenesis.

Oxygen consumption seemed particularly important in this regard; respiratory measurements were made on washed, vigorous mycelia over a range of temperature in an ultra-micro respirometer. With intervals of 3–5° over a range from 3–45°, it appeared that plots of rate *v.* temperature in degrees lent themselves to a separation of two ranges, 3–20° and 20–40°. However, plots of rate *v.* the reciprocal of absolute temperature gave curves which were slightly concave downwards; no 'breaks' or 'critical points' were noticeable. These data fit well with the recent mathematical formalization for temperature increments in biological processes elaborated by Morales[24] on the basis of the Johnson–Eyring formulation[25] of absolute reaction-rates. In this interpretation, two rate-limiting processes control the observed reaction-rates; at lower temperatures (3–20°) the splitting of substrate-enzyme complexes is rate-limiting, while in the higher range (20–40°) reversible enzymic denaturation becomes rate-limiting. Such a formulation does not imply 'breaks' in the plots of rate *v.* the reciprocal of absolute temperature. Rather, it leads to curves that are smoothly concave downwards.

No clues of the physiological mechanism underlying the *thermal dimorphism* of *Blastomyces* were obtained from these experiments on the effect of small temperature changes on oxygen consumption. When similar measurements were made on mycelial preparations exposed to large changes in temperature (15° or more) there appeared what is commonly termed 'overshoot', or exaggerated response, phenomena. (It should be pointed out that the process $M \rightarrow Y$ is obtained with these organisms following the transfer of a mycelial culture from room temperature to the 37° C. incubator—a jump of more than 15° C.) Following an abrupt increase from 5 to 20°, the rate of oxygen consumption was briefly higher than expected for the 20°-level, following which it rapidly recovered to the normal rate for the indicated temperature. (The brief higher level is not an artefact of technique.) An increase from 20° to 40° resulted in a tremendously increased rate of oxygen consumption that slowly levelled off to the rate anticipated for 40° C. If we view the rate of oxygen consumption as normally being determined in the range 5–20° by a constant k_1, which is a measure of the rate of enzyme substrate splitting and, in th range 20–40°, as the result of two simultaneous rate limiting phenomena k_1 and k_2 (the constant for reversible enzyme denaturation), we may write th following expression:

$$5^\circ \xrightarrow{k_1} 20^\circ \underset{k_2}{\overset{k_1}{\rightleftharpoons}} 40^\circ$$

where the arrow to the right indicates increasin velocity of reaction and that to the left (←, denotin reversibility) indicates a decreasing effect on velocity Since at any given temperature in the range 20–40 the rate of oxygen consumption is constant for man hours, we may conclude that k_1 and k_2 have achieve a steady state. The large, abrupt increases in temperature upset this steady state to produce a situatio which may be expressed by:

$$\underset{\underset{k_2}{\overset{k_1}{\rightleftharpoons}}}{20^\circ} \xrightarrow[\text{change of} > 15^\circ]{\text{abrupt}} \left[\xrightarrow[k_1]{40^\circ} \right] \xrightarrow{\text{time}} \underset{\underset{k_2}{\overset{k_1}{\rightleftharpoons}}}{40^\circ} \ \text{(gradual restoration)}$$

The temporary apparent suppression of the rate-limiting factor k_2 is deduced from the overshoot i oxygen consumption. That this 'apparent suppression' probably results from measurable difference i the speeds with which the two rate-limiting processe return to equilibria is seen from the difference i times required for the reappearance of a steady stat at 20° and at 40° after large jumps to these temperatures.

In view of the fact that the other aspects of th metabolism of *Blastomyces* investigated thus far other than oxygen consumption, are comparable fo the yeast and the mycelial forms, we are inclined t attach importance to the results for respiration, i the sense that they may indicate the physiologica basis for the observed thermal dimorphism. We ma conceive that the cell division enzyme complex (D lies at the end of a chain of consecutive reaction which produce its substrate (s); it is further conceivable that (D) must compete for (s) with anothe enzyme complex (X) which is concerned with cel elongation.

$$s \begin{array}{l} \overset{D}{\nearrow} \ \text{division} \\ \underset{X}{\searrow} \ \text{elongation} \end{array}$$

Let (s) be produced by reactions for which the rate limiting processes are only of the enzyme-substrat splitting category, and assume that (X) has a highe affinity for (s) than has (D). Under such conditions elongation will result and division will be suppressed If, for the reaction $s \xrightarrow{X}$ elongation, the rate limiting factor is the reversible denaturation of (X) it may be possible for the reaction $s \xrightarrow{D}$ division t predominate at higher temperatures. In view of th lag in 'adjustment' of the process in respiration whic probably is rate-limiting by reason of its reversibl denaturation, we might say that a parallel phenomenon, operating in a growth mechanism of th type conjectured, would result in a supply of (s saturating (X), thus permitting an initiation of th (D) reaction.

The actual nature of D, X and s (and definitive evidence for their existence) must be left for future nvestigations. In view of Hinshelwood's implication of the importance of the source of nitrogen for the $S \rightarrow F$ process in *Bact. lactis aerogenes*, and earlier work of Langeron and Guerra[26] along similar lines for the $Y \rightarrow M$ process in *C. albicans*, we may see ndications of the nature of (s). Viewing elongation as 'straight growth' and division as 'curved growth', t may reasonably be imagined that 'rigid' or 'flexible' molecules resulted respectively from the action of X or D. In this connexion the recent investigations of Jeener[27] and Lyons[34] on the fibrinogen-fibrin proteins are suggestive; the critical importance of —SH ⇌ —S—S— in this process makes it even more suggestive, since —SH maintenance inhibited ibrin formation, and —SH donors maintain spherical growth of yeast cells. The analogy between maintenance of cell division and the prevention of disulphide-link formation in a fibrous protein may actually be far more than a superficial one. As Astbury[35] has so fascinatingly written, ". . . the molecular plan of the keratin–myosin–fibrinogen group is one of the great primal ideas in vital architecture. . . . It represents a fundamental power of he cell of synthesizing elastic fibrous protein of a standard molecular form, yet whose details can be adapted to a variety of ends as the processes of differentiation demand." The ability of a cell to grow may then reside in its ability to form elastic fibrous protein, and its ability to divide may reside in its potential to prevent the formation of intermolecular disulphide links and resultant loss of molecular elasticity. Such a concept of cell division is, in fact, reminiscent of that elaborated by Rapkine[36] everal years ago, who held that cell division is accompanied by configurational rearrangements of cell protein resulting in an increase in the appearance of protein —SH groups.

In view of recent work[28] on the mechanism of action of acridines (proflavine, trypaflavine), we may consider some relationships of nucleic acid metabolism in $Y \rightarrow M$ phenomena. Acridines are believed o exert their growth- (and respiration-) inhibition effects by union with nucleoproteins of the cell[28]; this inhibition may be overcome by addition of nucleic acid[29,30]; nucleic acid-proflavine complexes have been prepared[30]. It is clear that the ribose nucleic acid content of cells that have undergone the $Y \rightarrow M$ process is greatly lowered; they are Gram-negative, and are stained scarcely at all by pyronin from the Pappenheim–Unna mixture. Yet these cells have grown and undoubtedly synthesized protein. Populations of elongated cells may be grown (excluding the possibility of 'redistribution' from the Y form) which are pyronin 'negative'[13]. Spiegelman and Kamen[31] have recently queried the correlation between nucleic acid metabolism and protein synhesis. Results from the study of the $Y \rightarrow M$ and $S \rightarrow F$ processes *appear* to augment their query. But f particular types of protein synthesis (and mainenance of elasticity) are involved in division processes, it may be that it is with these that nucleic acid metabolism is associated[16] during normal growth and cell division.

PHYSICAL PROPERTIES OF SUBSTANCES OF HIGH PERMITTIVITY

ON June 12, the Electronics Group of the Institute of Physics held a symposium on substances of high permittivity, the so-called ferro-electrics. Three papers were followed by a discussion. Original results were reported by speakers both in the last two papers and in the discussion—a sign of the considerable interest shown.

A survey of the electrical and crystallographic background of ferro-electricity was given by Dr. Vera Daniel (British Electrical Research Association). She pointed out that the essential feature of ferro-electric materials is that they consist of domains with a spontaneous electric polarization. With no external field and in equilibrium, the moments of these domains cancel each other. The effect of a field on a specimen of such a material is two-fold. It influences the polarization of each domain and it may also reverse the polarization of domains. The spontaneous polarization of an individual domain is an equilibrium property, and at any given temperature the differential of this polarization, with regard to field strength, defines an 'equilibrium' permittivity. The permittivity of a real specimen is made up of this equilibrium permittivity plus a contribution due to the reversal of domains. The latter contribution is necessarily very sensitive to structure and implies the existence of saturation effects; for if already all domains are aligned in the direction of the field, no further domains can be reversed. The reversal of domains also leads to hysteresis.

All ferro-electric materials are crystalline, and from the point of view of the crystallographer their properties imply unusual conditions. It is not rare for crystalline substances to have a spontaneous polarization; but in the majority of cases this does not depend appreciably on electric field strength, and domains cannot be reversed by a field. It is quite exceptional that the forces controlling the polarity are as weak as to be comparable with the energy of an applied field, which is the case for ferro-electrics. All known cases of ferro-electricity are connected with the change of a structure with spontaneous polarization into one without such polarization. These changes occur gradually over a temperature interval, the spontaneous polarization decreasing more and more rapidly on approaching a critical temperature, called the Curie point in analogy with ferro-magnetism. Thermodynamically, the change of structure may be a first- or second-order transition. The Curie point is associated with a sharp peak of the permittivity.

Dr. Daniel concluded by discussing experimental and theoretical work done on Rochelle salt, potassium dihydrogen phosphate and ferro-electrics of similar structures. Ferro-electric properties depend on very delicately balanced energy conditions, and their understanding presupposes a very thorough knowledge of the bonding of the crystal structure. It seems remarkable how much progress has been achieved in spite of the difficulties of the subject, even with regard to so complicated a substance as Rochelle salt[1].

Dr. D. F. Rushman (formerly of Philips Electrical, Ltd.) discussed the high permittivity titanates, such as barium titanate and its solid solutions with the titanates of other metals of the second group of the periodic system of elements.

These ceramic materials, the unusual electrical properties of which were discovered during the War, have considerable practical interest. In practice, barium titanate is prepared from barium carbonate and titanium dioxide at temperatures higher than 1,000° C. To form a dielectric it is crushed, sieved, and sintered at about 1,300° C., clay or other binder being added in small quantities, to reduce the porosity. The preparation is not simple, and care is required to produce a material of uniform quality. Dr. Rushman showed the effect of wrong firing conditions on the dielectric properties.

Dr. Rushman discussed in detail the experimental evidence which establishes the ferro-electric character of barium titanate and some of its solid solutions with other titanates. The permittivity-temperature curve shows a characteristic peak at the Curie point[2]. Saturation effects are shown very strikingly by the fall of the permittivity when the specimen is in a strong D.C. field, and the materials give characteristic hysteresis loops. It is possible to produce electrets, that is, specimens can be polarized and the polarization 'frozen in', producing a specimen analogous to a permanent magnet. The crystal structure[3] is tetragonal, with spontaneous polarization[4], in the ferro-electric temperature region and cubic, without spontaneous polarization, above the Curie point. The structural transition at the Curie point is curious in that the cubic and tetragonal phase co-exist over a temperature range of a few degrees. The specific heat has a λ point at the Curie temperature, a characteristic feature of ferro-electric and ferro-magnetic materials[5].

Dr. A. S. Devonshire (University of Bristol) dealt with the theory of dielectrics and ferro-electricity. He gave an account of original theoretical work on some features of ferro-electricity, and in particular on the spontaneous polarization in barium titanate.

The permanent polarization in titanates can be explained, Dr. Devonshire said, by the forces between electric dipoles. If a substance containing dipole breaks up into long narrow domains polarized along their length and the net polarization is zero, th mutual potential energy of the dipoles is $-\frac{2}{3}\pi P^2$ pe unit volume, where P is the polarization per uni volume. When an ionic crystal is polarized, it contain a set of pseudo-dipoles, formed by displacement of the ions. If the energy required to displace the ions is les than $\frac{2}{3}\pi P^2$, the polarized state will be the most stable one; that is, there will be a spontaneous polarization Dr. Devonshire here directed attention to a difference between ferro-magnetism and ferro-electricity. The interaction between electric dipoles is a long-rang force, that is, the force on dipoles is partly due to dipoles in distant parts of the domain. In contrast the forces which orient the magnetic dipoles in a ferro-magnet are almost entirely forces between nearest neighbours; the long-range forces are relatively very small.

The ferro-electric properties of barium titanate are due to the structure having a spontaneous polarization at temperatures below the Curie point. Dr. Devonshire classified the effect of temperature on the spontaneous polarization under three headings (1) Thermal expansion decreases the number o dipoles per unit volume. This means a decrease o polarization with temperature. (2) Thermal expansion decreases the restoring force on a displaced ion This means an increase of polarization with temperature. (3) Thermal oscillations tend to decrease th polarization with increasing temperature. The first of these effects is relatively small. The second two effects have opposite sign, but the same order of magnitude, and it is not possible to predict on theoretical grounds which predominates. Experimen shows that the polarization disappears at high temperatures. Hence the third effect must be large than the second.

The potential energy of the system is furthe decreased if the crystal expands along the direction of polarization so that it becomes more polarizable in that direction. This interaction between structure and polarization has the effect of increasing the change of polarization with temperature and accounts for the transition at the Curie point being of the firs and not of the second kind.

In the discussion, Dr. Rushman directed attention to some properties reducing the practical usefulness of titanates. One of these is their relatively low breakdown strength. Owing to the minimum thickness required for mechanical reasons, this is no serious disadvantage unless voltages above 500 V are used. Another disadvantage is the fact that the titanates, being ceramics, cannot be used in such thin layers as dielectrics like paper. The marked dependence upon temperature of the permittivity is also a drawback for general use. Dr. Rushman observed that in general a ferro-electric material can never be a really stable dielectric because its ferro-electric properties are due to a certain instability of its structure. Nevertheless, the high permittivity of the titanates makes them useful dielectric materials for special purposes.

Dr. H. F. Kay (University of Bristol) contributed data indicating the way in which domains in barium titanate single crystals are arranged. Domain boundaries follow 101 or 011 planes, and the domains are often laminar. Dr. Devonshire pointed out that this need not contradict his postulate that for the most favourable conditions of potential energy domains should be elongated. The large domains found optically may be subdivided into smaller domains of equal c direction but different direction of polarization. Dr. Kay then showed that the structural changes in barium titanate and solid solutions of barium and strontium titanate can be explained with surprising accuracy if one assumes the barium and oxygen ions to be rigid spheres with the conventionally accepted ionic radii. This assumption even gives the right value for the spontaneous polarization. However, as Dr. Kay pointed out, the physical meaning of the changes could scarcely be so simple.

Mr. M. G. Harwood (Philips Electrical, Ltd.) reported experimental results regarding the lattice parameters of the tetragonal, ferro-electric form of barium titanate over a wide range of temperature, directing particular attention to changes which occur at points below room temperature, where other workers had previously found anomalies in the dielectric properties. The axial ratio c/a, although on the whole increasing steadily with decreasing temperature, shows discontinuities at approximately +5° and −70° C., a sudden drop in the ratio being recorded at each of these temperatures. This was analysed in terms of anomalous changes of the lengths of the tetrad and diad axes, which at all other temperatures vary in a continuous and regular manner. X-ray and optical examination shows that at these two particular temperatures, where two structures co-exist over about 10° C., the domains change their direction of polarization in the absence of an applied electric field. The reason for this still awaits an explanation; but it may account for the peaks in permittivity at these points.

GEORGE STEPHENSON, 1781-1848

ON August 12, 1848, a century ago, George Stephenson died at his home, Tapton House, Chesterfield, at the age of sixty-seven, and was buried in Trinity Church in that town. For some years he had been more concerned with his properties than with railways, taking special delight in horticulture and his Derbyshire collieries. His father had been a fireman at a Northumberland coal mine, and Stephenson himself had passed his boyhood amidst coal pits, pumping and winding engines. He had become an assistant fireman when fifteen, was the mechanical engineer at Killingworth Colliery at thirty-one, built his first colliery locomotive at thirty-three; his first railway was that laid down at Hetton mines a little later, and the famous Stockton and Darlington Railway, of which he was the engineer, was designed primarily for mineral traffic. His interest in collieries was therefore life-long.

The story of Stephenson's rise from obscurity to fame is a familiar one in industrial history. Born in the lowliest circumstances, he enjoyed none of the early advantages of Watt or Smeaton or Rennie, and it was only when eighteen, through his own perseverance and industry, he learnt to use a pen and entered the magical world of books. His mechanical ingenuity, however, was evident from the first; and it was only a year after he constructed his first locomotive, *Blucher*, that he devised the 'Geordie' miners' safety lamp, for which he was given £1,000 by his fellows. The reputation thus gained was increased by his success at Hetton, and at a time when the mechanical world was divided over the respective merits of horses, stationary engines and 'travelling engines' for industrial railways he was able to prevail upon the Darlington manufacturer, Edward Pease (1767–1858), to use locomotives, except for steep inclines, on the Stockton and Darlington line.

Moreover, through the confidence Stephenson inspired, he was enabled to secure the co-operation of Pease and others in founding the first locomotive-building works in the world. Set up at Newcastle in 1823, under the title R. Stephenson and Co., the firm supplied many of the most famous of all early locomotives. George Stephenson was then in his 'forties, his son Robert in his 'twenties, and it is impossible to dissociate the work of one from the other. Generally it may be stated that the period 1820–25 saw the construction and opening of the Stockton and Darlington Railway and the period 1825–30 the construction and opening of the much more important Liverpool and Manchester Railway, on which in 1829 took place the epoch-making Rainhill locomotive trials, which decisively placed the steam locomotive in the position of supremacy.

Needless to say, the steam railway would have come if George Stephenson had never lived; but it was his good fortune to be in the current of affairs at a critical time, and to be endowed with both the mental and physical characteristics necessary for the task which lay ahead. The locomotives of Trevithick, Hedley and Blenkinsop had preceded Stephenson's, while railroads or tramways had been in use a very long time. Then, too, many men, without any claims as inventors or engineers, saw what was possible, and their views were shared by men of high commercial standing. Before the Stockton and Darlington Railway was started and before Stephenson's factory at Newcastle was opened, in 1820 Thomas Gray, who died in poverty two months after Stephenson passed away, published his little book entitled "Observations on a General Iron Railway", which ran through five editions in five years, and contained plans for trunk lines from London to Falmouth, Dover, Edinburgh, Holyhead, etc. Still other promoters were William James, Nicolas Wood, the mining engineer, and Charles Maclaren, the editor of *The Scotsman*.

By this time the advancement of civil engineering and mechanical engineering in the eighteenth century had given Britain great constructional works and engine shops, the supply of iron for rails, boilers and engines was ample and many men were ready to follow in the footsteps of Stephenson. His lines and his shops, too, provided the training grounds for the future railway engineers, and so it was that with the completion of the Liverpool and Manchester Railway the great era of railway construction began. In Great Britain alone, by 1840 there were more than 800 miles of lines open, by 1860 more than 10,000 and by 1880 some 18,000 miles. Not a single engineer of those days would have denied that the world was entitled to regard George Stephenson as 'the father of railways'.

NEWS and VIEWS

Sir Francis Darwin (1848–1925)

THE third son of Charles Darwin gave early evidence of a scientific bent. Born at Down a century ago, on August 16, 1848, he took his degree at Cambridge in 1870 with a first class in the Natural Sciences Tripos. After studying medicine at St. George's Hospital, London, and obtaining the Cambridge M.B. in 1875, he acted as his father's secretary for eight years. In 1884 he was appointed lecturer, and four years later reader, in botany at Cambridge. At that time plant physiology was beginning to supersede the study of systematic botanical description. Francis Darwin's class-book "The Practical Physiology of Plants" (1894) went into several editions, for it was the first book of its kind in Britain. His researches on growth curvatures in plants and on the control of water-loss by plants attracted considerable attention. He was a popular lecturer, being engagingly simple and direct. Though possessed of strong prejudices and inclined to be intolerant, his was a lovable personality, charming, kindly and humorous. He was an accomplished musician and devoted to dogs, which, unlike human beings, never bored him. Many honours came his way. Elected a fellow of the Royal Society in 1882, he was foreign secretary during 1903–9 and vice-president in 1907. In the following year he became president of the British Association, and he was knighted in 1913. He died at Cambridge on September 19, 1925. It is appropriate that his best and best-known book should be the "Life and Letters of Charles Darwin" (1887).

Statistics of the Ministry of Labour and National Service

THE standing Interdepartmental Committee on Social and Economic Research was appointed in January 1947 to survey and advise upon research work in Government departments and in particular to bring to the notice of departments the potential value for research purposes of the material which they collect, and to suggest new methods and areas of collection. It has also to advise on how there could be made available to research workers information gathered for their own purposes by the departments which has potential value as material for research. The Committee has selected as the first major department for survey (London: H.M. Stationery Office. 9*d*. net) the Ministry of Labour and National Service, which has a tradition of co-operation with research workers. The first results of this survey have been published as a booklet which describes the development of the Ministry of Labour's Statistical Service and the information at present collected by the Ministry on employment and unemployment, wages, earnings, hours and industrial relations, retail prices and family budgets, the changes which have occurred in the form of collection and the effect upon the comparability of successive statistics. In addition to a list of published sources of information, there is included a subject index to published sources of Ministry of Labour statistics. The booklet is experimental in form; but it is hoped that it will prove of value to teachers and students in the universities as well as to other research workers, and criticism and suggestions for improvement will be welcomed by the Committee.

Marconi Transmitters for East Africa

A NEW system of short-wave radio communication is planned in East Africa, where a total of forty-eight Marconi short-wave transmitters are to be installed to provide a comprehensive communications network for ground-to-air and point-to-point communications for the rapidly expanding civil aviation services—both local and trunk routes—and for administrative, public and meteorological traffic. The new services, which will operate throughout the three territories of Kenya, Uganda and Tanganyika, are required to meet the needs of post-war expansion and re-organisation of the East Africa Posts and Telegraphs Department's Services. Two of the latest types of Marconi transmitters have been chosen for this new service. They are Type *TGS*. 541—a 200-watt transmitter with a frequency range of 1·5–23 Mc./s., and Type *TGS*. 501—a 100-watt set covering a frequency range of 1·5–13 Mc./s. Both types of transmitter are compact, easily operated equipments designed for operation on radiotelephony or telegraphy. Special features include crystal-control with provision for the rapid selection of any one of six working frequencies—a particularly useful asset where a large volume of traffic is handled. Frequency tolerances are well within the very fine limits laid down by international regulations. Work has already begun at the Marconi Company's Chelmsford Works on the construction of the first of these transmitters which are to be installed at Mbeya Airfield, Tanganyika.

Quarterly Journal of Mechanics and Applied Mathematics

THIS new journal is intended to provide a medium for the publication of papers on classical mechanics and mathematical techniques. The first number dated March 1948, which has recently been issued contains papers by D. C. Pack, R. Hill, D. R. Hartree and S. Johnston, W. G. Bickley, S. Goldstein, A. D. Young, M. J. Lighthill, and Sir Geoffrey Taylor. Rather more than half of these papers deal with hydrodynamics and its applications to aerodynamics or internal ballistics; the others deal with elasticity or methods and results useful in computation. The editors are Prof. G. C. McVittie and Prof. V. C. A. Ferraro, assisted by an editorial board which includes most of the leading British applied mathematicians. The publishers are the Oxford University Press, and the subscription is £2 a year for the four numbers.

Earthquakes during June

DURING June there occurred at least nine world-shaking earthquakes and a great number of smaller ones. The greatest two of the month were that on June 28, which caused heavy casualties and severe property damage in and around Fukui, West Honshu, Japan (*Nature*, July 10, p. 57) and which gave ground amplitudes at Durham of 115μ, and that on June 30 which caused casualties and property damage on the island of Levkas and the nearby mainland of Greece and gave ground amplitudes of 220μ at Kew. The other great shocks were on June 15 near the southern coast of Honshu, Japan; on June 18 in the Solomon Islands region; on June 21 in the Celebes Sea; on June 27 (2) off the northern coast of Honduras and south of the Alaska Peninsula; and on June 29 (2) in the Samoan Islands region and in Transcaucasia. An earthquake only slightly less intense occurred on June 13 from a focus the epicentre of which was near lat. 43° 31′ N., long. 12° 8′ E. This caused some property damage and at least one death at Sa epolcro in the Italian Province of Arezzo. Also uring the month there was a swarm of earthquakes ı the Karlsruhe, Rasstat, Lauterbourg area. The warm began on June 1 and lasted practically the hole month, the greatest shock of the series being lt on June 7 with scale VI to VII (some chimneys own) at Karlsruhe. The epicentre of this shock was ear lat. 49° 04′ N., long. 8° 19′ E. some 9 km. orth-west of Karlsruhe, and the depth of focus has een estimated at 20–30 km. The energy of the ocks of this swarm did not travel far, but was ecorded by the seismographs at Strasbourg, Stuttgart nd the Swiss observatories. Apart from the observa- ories mentioned above, reports for the month have lso been received from the U.S. Coast and Geodetic urvey, Aberdeen, Beograd, Cleveland (Ohio), De ilt, Toledo and Uccle.

ialactic Noise

R. v. d. R. Woolley has discussed in a recent aper (*Mon. Not. Roy. Astro. Soc.*, 107, 3; 1948) the ieory of the origin of the galactic radiation. Since udio workers consider it short-wave radiation and ectroscopists regard it as very long-wave radiation, is undesirable to refer to it by a name embodying ny idea of wave-length, and the appropriate term noise' has been adopted since it can be heard on the rphones. Eddington discussed the temperature of nterstellar space in "The Internal Constitution of ie Stars", and estimated it at about 10,000°; but ter he suggested that the absorption in space of ltra-violet quanta would reduce the temperature. 3y temperature he meant the parameter appearing ı the Maxwellian velocity distribution of the free ectrons.) Woolley investigates the problems of mperature and the degree of ionization in inter- ellar space, and concludes that if the noise is due free-free transitions, it must certainly come from ot regions in interstellar space and almost certainly om regions where the density is above the average. ı these circumstances, if 'cold' regions, that is, gions of low hydrogen ionization, do not contribute ppreciably to the noise, then an observed amount galactic noise from a particular part of the sky nplies a minimum bright hydrogen emission from ıat part. If observation fails to reveal this bright ydrogen emission, the only conclusion is that alactic noise is not due to free-free transitions. If ie noise is due to free-free transitions, it is shown ıat the minimum number of Hα quanta received er sq. cm. per second per unit solid angle of the sky within reach of observation with modern equipment.

inematograph Films of Living Cells

C. C. Speidel (*Amer. Scientist*, 36, 237; 1948) escribes with some very fine illustrations the results e has obtained by fast cinematography of cells inside ie living animal. He used regenerating tail tissue f the tadpole for his observations, and shows that ellular organisation may be studied here with results hich tissue cultures cannot provide. Regeneration f nerve fibres, showing the manner in which their irection and anastomosing take place, mitosis in a erve cell and the relative movements of the two aughter nuclei, the movement of lymphocytes and iapedesis of leucocytes are among the many beautiful esults of this method of observation. The salvaging extravasated blood cell by cell by the sprouting a lymph vessel is startling, while the movement of uscle fibres in contraction and relaxation may be followed step by step. It would seem that this method of analysis would be of great value in further studies of development, especially in the little-known differentiation of plant tissues.

Tests of Mosquito Repellents

When Australian forces began campaigning during the Second World War in the highly malarious islands of the south-west Pacific area, a very urgent need was an effective mosquito repellent. Bulletin No. 213 (1947) of the Commonwealth of Australia Council for Scientific and Industrial Research describes laboratory and field tests conducted by Major R. N. McCullough and Capt. D. F. Waterhouse with this object in view. More than 125 substances were tested for use as repellents against both anopheline and culicine mosquitoes. The chief species used in these experiments were *Anopheles punctulatus farauti*, the yellow-fever mosquito *Aedes ægypti*, and the common pest mosquito *Aedes vigilax*. The work involved was a co-operative investigation between the Council for Scientific and Industrial Research and the Army. Taking all factors into account, dimethyl phthalate was by far the most satisfactory repellent tested. Also, it is almost completely odourless and has very little or no irritant effect on the skin of the hands and face, to which it is applied. A number of other synthetic and naturally occurring substances were tested with indifferent results. Many essential oils were quite ineffective, while the two most promising were too irritant to use. Pyrethrum preparations gave consistently poor results. The treatment of clothing with dimethyl phthalate prevented mosquitoes from attacking through the material, except to a very limited degree, up to 72 hours after application. As a result of these investigations of repellents, and of those on a larger scale in the United States, the manufacture of adequate quantities of dimethyl phthalate was organised and the substance made available to the Australian fighting forces in 1943, some special forces being supplied with it as early as March 1943.

Control of Weeds

Prof. G. E. Blackman, in a short paper on "Recent Developments in the Control of Weeds" (*J. Roy. Hort. Soc.*, 73, 5; May, 1948), summarizes some useful results on the effectiveness of various selective weed-killers. Sulphuric acid gave the best control of goosegrass, *Galium aparine*; methyl-chloro-phenoxy-acetic acid gave the best kill of shepherd's needle, *Scandix pecten-veneris*, and common red poppy, *Papaver rhœas*; and dinitro-*ortho*-cresol was most toxic to scentless mayweed, *Matricaria inodora*, but also gave control equal to the acetic acid compound of *P. rhœas*. The use of sulphuric acid is still most effective, particularly against weeds of the onion crop. Spraying with this acid gives about 90 per cent of the yield obtained by hand weeding and hoeing, but at very much less expense in labour. Charlock is susceptible to control by growth-substance sprays at all stages from seedling to flowering, though poppies are susceptible only as seedlings.

Tomato Spotted Wilt Virus

The disease of tomatoes caused by spotted wilt virus often shows considerable variation in severity. D. O. Norris has now shown (Bull. 202, Coun. Sci. and Ind. Res., Australia; Melbourne, 1946) that this is due to varying combinations of at least five strains of the virus. The paper describes and figures the symptoms of these strains on sixteen host species, and indicates suitable tests for the presence of strains in a particular disease. The thermal death-point of spotted wilt complexes is considered to be about 10° C. higher than the usual value of 42° C. This is a rather unwelcome discovery from the point of view of possible control. On the other hand, the finding of a high degree of resistance to spotted wilt by *Lycopersicum peruvianum* is likely to be of considerable importance in breeding.

Clutch and Brood-size in the Robin

The inquiry into clutch and brood-size in the robin (*Erithacus rubecula*), which was first reported by David Lack in 1946, has now been closed. Later observations show that the breeding season in Holland is later than in Britain but is earlier in North France, Germany and Switzerland than inland in Europe at a similar latitude (*British Birds*, 41, No. 4; April, 1948). The tendency for the average clutch-size of the robin in England and Wales to be highest in May, lower in April, and lower still in March, June and July has been confirmed It has also been shown that the average clutch-size is different in different years and there may be a correlation between fine weather and higher clutch-size. The average clutch-size in Ireland is approximately the same as in England and Wales, but in Scotland the average clutch-size is higher than in England and Wales. Nesting is more successful in May than in April, possibly because in April the ground vegetation is not so well grown as in May, leaving the nests less exposed to predators.

International Committee for Bird Preservation

The report of the British Section of the International Committee for Bird Preservation (The Secretary, c/o British Museum (Natural History), Cromwell Road, London, S.W.7) is a record of much good work. For some years past naturalists and others have been perturbed by the decline in the wildfowl population of the world, and, among other things, the report contains an account of the Committee's work in investigating the situation as it affects the wildfowl of Europe. Among the activities are the ringing of duck to trace their migration routes. A duck decoy at Orielton is being used for this purpose, and ringing on a lesser scale is being carried out at other decoys in Great Britain. In 1947, the headquarters of the Committee, previously in Brussels, were transferred to London, and the British Museum (Natural History) is now the centre of the organisation, which has thirty-four national sections from all five continents.

The Film in Scientific Research

The Sciences Committee of the Scientific Film Association is arranging a one-day conference on "The Film in Scientific Research", to be held on October 12 at the Royal Institution, London. The chair will be taken by Mr. J. E. Cummins, chief scientific liaison officer in London of the Australian Government, and the Conference will be opened by Sir Robert Watson-Watt. The Conference will include discussions by British and foreign men of science on the value of scientific films as a research tool in various branches of science; the function of the research film in giving up-to-date information in a particular field; scientific films as an aid to the training of scientific workers; scientific films as a medium for explaining to the general public important results of scientific research; and techn aspects of the use of films in scientific research. Conference will conclude with a two-hour showin British and foreign research films. Material sugge for discussion and information as to the existenc availability of research films suitable for showin the Conference should be sent to the Hono Secretary, Sciences Committee, Scientific Film A ciation, 34 Soho Square, London, W.1, as soo possible.

Announcements

We regret to announce the following deaths:

Mr. S. G. Brown, F.R.S., known for his work on gyroscopic compass and numerous other mechan instruments, on August 7, aged seventy-five.

Mr. Harry E. Burton, principal astronomer and h of the Equatorial Division of the U.S. Naval Obse tory from 1929 until June 30, 1948, on July aged seventy.

Mr. J. R. Cowie, chairman of Council of the Bri Electrical and Allied Industries Research Associat on August 5.

Dr. Henry Guppy, C.B.E., librarian of the J Rylands Library, Manchester, on August 4, a eighty-six.

The chairman of the Royal Society's Lib Committee, Prof. E. N. da C. Andrade, has accep an invitation by the Council to become hono librarian to the Society during his tenure of chair ship of the Library Committee.

Sir Lewis Fermor, director of the Geolog Survey of India during 1932–35, has been ele *Correspondant Etranger* of the Société Géologiqu France.

Sir Frank Stockdale, chairman of the Colo Development Corporation, has been appointed c man of the governing body of the Imperial Colleg Tropical Agriculture, in succession to Sir Macfadyen, who has been associated with the Col since 1928.

Mr. Seton Lloyd, technical adviser to the Di torate of Antiquities in the Government of Iraq, been appointed director of the British Institut Archæology at Ankara in succession to Prof. Garstang, as from March 1, 1949.

Mr. R. McChlery, former Rhodes scholar since 1926, a member of the Agricultural Departm Salisbury, has been seconded to the Central Afr Council to take up the new appointment of Cen African Scientific Liaison Officer in the Un Kingdom, and to establish a Central African Scien Liaison Office in the British Commonwealth of Nat Scientific Offices, London.

Dr. A. E. A. Werner has recently joined the of the National Gallery, Trafalgar Square, as rese chemist. He was previously reader in chemistr Trinity College, Dublin.

A Conference of German Hygienists and Mi biologists is being held at Stuttgart during August 27. Among the topics to be discussed are: tu culosis in animals and its chemotherapy; immun tion against virus diseases; milk hygiene in Germa human helminthiasis and its chemotherapy; hu and animal trichinosis; rickettsia toxins; phology and ecology of bacteria; bacteriology enteritis; serum reactions, etc. Particulars ca obtained from Prof. G. Lutz, Heusteigstr. Stuttgart-S.

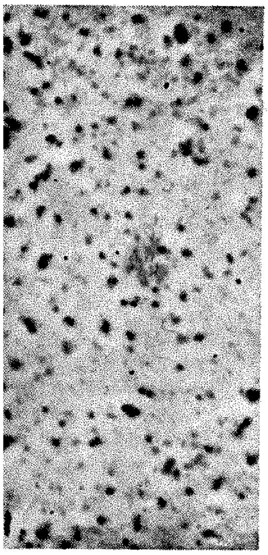
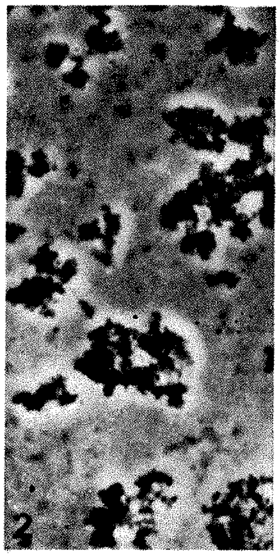
Phase-Contrast Microscopy of Viruses

Those who have used phase-contrast microscopy ll have been impressed by the apparent high solving power of the method. It is frequently ssible to observe very fine fibrils and particles with clarity hitherto only obtained by dark-ground umination. Thus, I have observed living *Leptospira*, id to be only 0·15 μ in width, as well as very small anules inside bacteria.





It was to be expected, therefore, that at least the rger viruses would be visible by phase-contrast umination, and this has now been verified. Fig. 1 ows a smear of psittacosis virus (× 1600), and g. 2 one of vaccinia (× 1600). The preparations ere unstained and mounted in water. It is important distinguish between ***visibility*** and ***resolution*** of the rticles. The photographs were taken with commercial (Cooke, Troughton and Simms) equipment, ing an oil immersion lens, rated N.A. 1·3 with ase-ring diameter approximately two thirds of the erture. The expected resolution under these contions, using green light, would be of the order 0·3 μ. One would thus scarcely expect to obtain true resolution of virus particles; but that does not eclude the possibility of detecting their presence. ius, the vaccinia particles seemed spherical, not rrel-shaped, as in the electron microscope. The tter appearance may, of course, be due to a drying tefact.

As a rough approximation, it would be expected at particles below the limit of resolution would pear to remain about the same order of size, but ould have less contrast, appearing in shades of ey instead of black. The visibility of small particles the phase-contrast microscope depends on conast, which is in turn governed by the refractive dex of the particles and by the characteristics of e apparatus. Leaving aside the possibility of improving contrast by variation of the refractive index of the mounting medium, perhaps the most hopeful method of increasing the visibility is by alteration of the phase, and particularly the amplitude, characteristics of the phase plate. Given favourable material, there is probably no reason why much smaller viruses should not be seen, using a strongly absorbing phase plate with an intense light source.

It remains to be seen how useful the method will prove in virus research. It is valuable in that it allows fresh unstained material to be used; but it is, of course, non-specific and there is no simple means of distinguishing viruses from other small particles. An obvious application is to the study of the development of virus bodies in living cells.

I wish to thank Prof. S. P. Bedson for supplying the virus material.

Experimental Hydronephrosis Studied by the Colchicine Method

The colchicine method was first used to study compensatory hypertrophy of the kidney by A. P. Dustin and S. Zylberszac[1,2], who noticed that a few days after ligation of the ureter, colchicine induced numerous 'stathmocineses' (arrested mitoses) in the kidney (Fig. 1).

This phenomenon has been reinvestigated in the adult rat, nine hours after injection of 2·0 mgm./kgm. of colchicine, mitosis being counted in the obstructed and the opposite kidneys. The total number of divisions was counted in median sections and, in order to compare the figures more accurately, these were corrected per 100 gm. of animal weight (Fig. 2).

In the obstructed kidney, two days after ligation, numerous stathmocineses are found in the interstitial cells, convoluted tubules, loops of Henle, distal convoluted tubules and collecting tubules. None is seen in the glomeruli. The mitoses remain numerous during the five succeeding days, especially in the proximal convoluted tubules. After one week, mitoses decrease as the kidney undergoes progressive atrophy through dilatation of the pelvis. In the opposite kidney, mitoses in the tubules increase on the

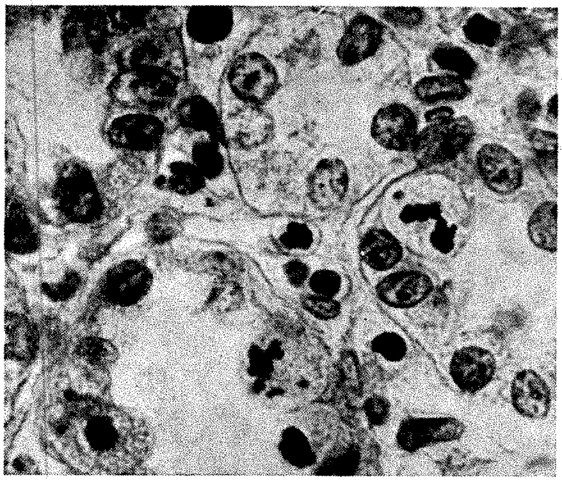

Fig. 1. Stathmocineses in convoluted tubules six days after renal obstruction

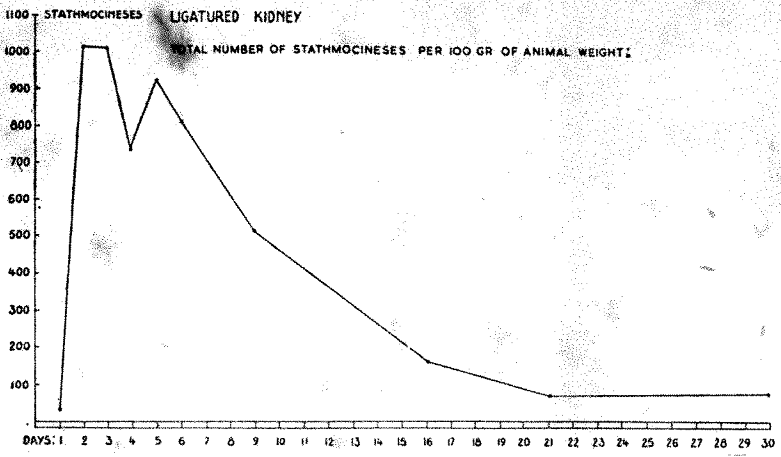

Fig. 2

second day after ligation, and reach a maximum at four days. The number of these mitoses remains at about the same level for as much as thirty days, the level being similar to that observed by the same method in compensatory hypertrophy.

These results are, in our opinion[3], comparable with those of Hartman[4], and Bollman and Mann[5]. These authors created uretero-intestinal fistulæ, leading to a slow reabsorption of urine in the intestine. They observed hypertrophy of the kidneys and also an acceleration of compensatory hypertrophy, with numerous mitoses in the tubules. Wilson[6] supposed that the hypertrophy of the kidneys may be induced by some urinary components. In hydronephrosis, their reabsorption by the kidney tubules would first promote mitoses in the ligated kidney. Soon after, these same substances, taken back by the general circulation, would stimulate cellular proliferation in the opposite kidney.

These experiments may be expected to throw more light not only on the mechanism of compensatory hypertrophy, but also on the chemical nature of the stimulus. Detailed results will be published shortly in the *Bulletin de l'Académie Royale de Médecine de Belgique.*

Induced Adenocarcinoma of the Stomach in Mice

THE great rarity of malignant tumours in the glandular stomach of all lower animals is generally admitted. The only records of spontaneous adenocarcinoma in mice seem to be three cases among 142,000 post-mortem examinations by Wells, Slye and Holmes[1], two in *Mus musculus* and one in *Peromyscus*. Strong[2] has reported adenocarcinoma in mice of his *NHO* line, derived from ancestors injected with methylcholanthrene and selected for resistance to local sarcoma-indu
tion ; but these animals are
representative of the species.

Two series of mice fed by
with cotton-seed oil previou
heated to 350° C. for four ho

the fore-stomach but no lesion of the glandul
stomach.

In repetitions of this experiment, only tumours
the fore-stomach have so far occurred.

These experiments are summarized in the acco
panying table.

In the second series of experiments, mice of simil
origin were fed on powdered rat-cake containi
0·5 per cent by weight of black pepper. The drinki
water contained 1·0 per cent heated cotton-seed
in soap solution as previously described. Of fi

Diet	Initial No. of mice	Stomach tumour incidence in survivors after first tumour	Duration of expt. at time of first tumour (days)	Diagnosis
Heated cotton-seed oil plus croton oil	48	3/9	540	Single squamou papilloma; 1 mixe squamous papill oma, squamous car cinoma and adeno acanthoma; 4 squa mous papillomas
	12	1/3	387	1 big papilloma
	12	1/9	406	1 small papilloma
	12	1/5	452	1 medium papillom
Croton oil only	12	1/6	487	1 small papilloma
Unheated cotton-seed oil only	12	1/11	310	Polyposis of pylori canal
Cotton-seed oil plus croton oil	12	1/2	501	Polyp in duodenum close to pylorus

rvivors for sixteen months, one died at that time ith a large ulcerated tumour involving the pylorus ıd proximal part of the duodenum. This proved be an adenocarcinoma, which had invaded the ncreas and a lymph node by direct extension. The her four survivors are still living after twenty-four onths of experiment.

In another experiment, twelve mice on similar et yielded no tumours in two that survived for ore than fifteen months. In 309 mice of similar igin in other experiments not involving known rcinogens, no gastric tumours were found.

We have not been able to identify any known rcinogen in any of the heated fats or lipids, examed by methods that will detect one part in ten illion of 3 : 4-benzpyrene. Moreover, even the esence of traces of known carcinogens would not count for the induction of adenocarcinoma of the omach, since very large numbers of mice have been inted with potent carcinogens in many laboratories ıd must have licked off and swallowed considerable nounts without a single case of gastric adenorcinoma being recorded. In this laboratory, mice d with known carcinogens have frequently deloped papilloma and carcinoma of the fore-stomach, ıt no tumours of the glandular stomach have curred.

Evidence that heated fats and lipids contain tential carcinogens was recently reviewed by one us[5]; but the induction of stomach tumours in mice feeding experiments with such substances are few d not generally accepted. Waterman[6] claimed one se of adenocarcinoma of the stomach in a mouse d with heated cholesterol oleate; but this has not en confirmed. Roffo[7] made numerous claims to ve induced adenocarcinoma of the stomachs of rats d on a variety of heated fats; but his copious ustrations do not support this diagnosis, and the ork has not been confirmed. The two cases reported re cannot be statistically assessed; but it seems ore probable that they were the result of the periment than of chance.

Physical Nature of Mouse Brain

Most histologists refer to the possible existence of ground substance in the brain. Neurofibrils or glial res of the cortex impregnated in a successful silver eparation by no means completely fill the space ailable. Presumably in life these nerve terminals d glial fibres are even further separated from one other, since the processes of fixation, dehydration, c., produce considerable shrinkage.

The physical properties of mouse brain as a whole, of a piece of excised cortex, suggest that this is a bstance with a continuous structure resembling that of a firm paste. It is opaque, soft, sticky, almost plastic, with a marked avidity for water.

Using either direct or dark-ground illumination, a film of fresh brain tissue appears granular, the separate granules adhering to one another and giving the whole field a hazy appearance. This granularity is evident at a magnification of × 80 and is best studied by means of dark-ground illumination at × 1,000[1]. Even at this magnification separate granules are not distinct. Some show Brownian movement; but the majority adhere to one another, forming a more or less continuous film. Pressure on the coverslip causes sluggish streaming movements; but on releasing the pressure the displaced parts recoil and the original appearance is restored. A piece of fresh cortex was placed in 1 per cent aqueous methylene blue for one minute, crushed between two slides and examined by direct illumination. Movement between the two slides or light pressure caused streaming displacements of the blue cortical cells in an unstained granular matrix. On cessation of movement or release of pressure the original grouping of cells was restored. The cells themselves showed marked elasticity and could not be ruptured. They were intact, suggesting that the granularity was not due to cell debris. Heavier pressure merely thinned the film by causing a gliding movement of brain substance towards the edge of the preparation with extrusion beneath the borders of the covering slide.

It has been pointed out that the cells and fibrils impregnated with silver do not occupy all the available space in a histological preparation. It seems improbable that the granularity described merely represents the fresh state of those structures which become impregnated with silver in fixed tissue. A strong impression is received that this granular substance is the ground substance of the brain, being present in considerable quantity in the mouse cortex.

Some Unusual Findings on the Carcinogenic Action of Urethane in Mice

The induction of pulmonary tumours in mice following ethyl carbamate (urethane) treatment was originally described by Nettleship, Henshaw and Meyer[1] and has been confirmed by numerous workers. Similar effects of urethane in the rat have been noted by Jaffe[2]. The lung tumours described have been adenomata, usually multiple, appearing by three months after oral or injected, single or multiple doses of urethane (solutions of 5 or 10 per cent). In histological appearance the tumours are the same as spontaneous lung tumours arising in strain *A* mice and are of relatively low-grade malignancy. Successful transplantation has not been reported. The findings reported below were obtained on Rockland 'Swiss' albino mice in experiments investigating the carcinogenic action of urethane. The preliminary results obtained are so unusual that they are presented in a very incomplete form, so that the effects may be looked for by other investigators and the apparent action considered by those using urethane for clinical therapy. More detailed results will be presented shortly from a repetition of these and other experiments now in progress.

(1) Seven young female mice, 20 gm., received a single subcutaneous injection of 25 per cent urethane in a 5 per cent solution of zinc acetate, 0·1 c.c. per 10 gm. body weight, with the view of slow absorption. Such an injection caused a local tissue necrosis which healed in two to three weeks. After three months and four months respectively, in two mice a rapid general enlargement of lymph glands was noted. Both animals, at autopsy three weeks later, showed extensive lymphosarcoma, all glands being involved and markedly enlarged. Histologically the tumours were highly malignant, and extensive spread to gut, liver and kidneys was noted. The usual lung adenomata were also present. A third mouse after five months developed a slower growing tumour behind the humerus (at least one inch from the injection site). At autopsy a large, spongy, blood-filled tumour was found. Histologically the sections showed a malignant hæmangio-endothelioma, and no metastases were noted. Lung adenomata were present. Spontaneous malignant tumours of these types have never been observed in more than a hundred mice of the same strain and age used for other experiments in the laboratory. Control experiments using 25 per cent urethane and 5 per cent zinc acetate alone, and other substances causing retardation of absorption[3], are not yet complete.

(2) The lungs of a mouse containing multiple large adenomata induced by previous urethane treatment (discontinued for the previous five months) were ground in saline and injected into sixteen mice. One half of the group received intrapleural, and the other half subcutaneous, injections. After six months, four of each group were killed. Two mice of the first group and all four mice of the second group showed single or multiple lung adenomata. These tumours were typical of those induced by urethane injections.

(3) The lungs of mice which had received a single subcutaneous injection of 0·1 c.c. per 10 gm. body-weight of 5 per cent urethane 3, 6, or 24 hours previously were ground up and injected into normal female mice. The equivalent of one lung was given to each animal by subcutaneous injection. Four animals of each of these three groups were killed five to six months later. Eleven of the twelve animals showed single or multiple lung adenomata similar in all respects to those caused by urethane injections. No other lesions were noted.

(4) Experiments using lung suspensions similar to those of paragraph (3), but made from animals which had received three daily injections of urethane, showed the same result, three of four mice developing lung adenomata.

(5) One control experiment was performed in which lungs from normal uninjected mice were administered in the same fashion under the same conditions. At autopsy, three mice which had received the injections did not show any lung adenomata.

It is obviously inadvisable to speculate on the significance of these preliminary experiments until more extensive ones have been completed. It appears, however, that rapidly growing, highly malignant tumours have been produced in mice following the injections of a strong urethane solution and zinc acetate. In other experiments a suspension of the lungs of mice which had received small doses of urethane, when given subcutaneously, produced adenomata of the lungs in a high percentage of animals. Although it is possible that the injected urethane might be concentrated in the lung tissu there was no experimental evidence to suggest th as the explanation of these observations.

This work has been carried out with grants in ai from the National Cancer Institute of Canada an the Ontario Cancer Research Foundation.

Reaction of Effector Cells to Chemical Transmitters

Earlier work has led us to the view that th intervention of peripheral elements has a fund mental role in the regulation of nervous activity This regulation, in fact, is not exclusively conditione by the nature of the transmitter or by its mode formation. It depends to a great extent on the mor or less specific reactions of the effector cells to th substances liberated by nerve stimulation. Thus tw transmitters, acetylcholine and adrenalin, act in different way on organs like the heart and th intestines, which present different histological stru tures. But adrenalin causes contraction of the uter of the pregnant cat and relaxation of the uter of the non-pregnant cat, that is, the action of th same transmitter is dependent on the functional co ditions of the reacting tissue. This suggests th possibility of local intervention of sex hormones i the peripheral regulation mechanisms of the uterus for it has been shown by Courrier that these hormon are capable of direct action on that organ and th the hormonal antagonism between œstrin and pro esterone, for example, is directly concerned with i effector cells.

We have therefore carried out more general exper ments on the isólated uterus of the rabbit, whic was the test-organ of Courrier, to find out to wha extent the responses of this organ to acetylcholin and adrenalin may be influenced by previous trea ment with different sex hormones.

The rabbit uterus reacts to acetylcholine as we as to adrenalin by contraction. This analogous actio is remarkable; for the effects of both are not onl inhibited by atropine, but also sensitized by eserin The actions of the two transmitters can, howeve be differentiated by yohimbine, which reduces th effect of adrenalin without modifying that of acety choline; and we observed also that relatively sma doses of adrenalin could produce contractions i uteri which showed very slight sensitivity to acety choline. It thus appears scarcely likely that adrenali produces its contracting effect by mobilizing acety choline in that organ.

This curious synergism of the two transmitters not affected by sex hormones. The untreated uteru of very young animals is absolutely insensitive to th two substances, and becomes sensitive to both afte 30–50 γ of œstrin have been administered to th animals over a period of several days. The sam modifications occur with the uteri of ovariectomize rabbits. This evolution of sensitivity: (1) does not increase with the administration of larger amounts of the hormone than the active dose; (2) is not peculiar to œstrin, but can also be obtained with testosterone (1–10 mgm.), progesterone (1–10 mgm.), desoxycorticosterone (1–10 mgm.), or with a mixture of œstrin and progesterone initiating the classical transformation of the uterus mucosa described as 'dentelle'. The reaction of the uterus to the transmitters seems, however, more marked after the administration of testosterone or œstrin than after that of desoxycorticosterone.

But this apparent uniformity of response hides very complex cell changes. When the rabbit uterus is immersed in Tyrode solution for 15–90 min. in the presence of oxygen and at a temperature of about 37°, it gives off a substance which is capable of decreasing the muscular tone of an isolated intestine preparation. This tone can be increased by the fluid obtained in the same circumstances from the uterus of an animal which has been treated with testosterone. The latter effect may also be observed, though generally to a lesser extent, with fluids obtained from rabbit uteri treated with progesterone alone or combined with œstrin. The liquid obtained after desoxycorticosterone sometimes provokes an amplification of the spontaneous intestinal movements. We conclude from these results that sex hormones are capable of creating modifications in the biochemical reactivity of the receptor cells of the uterus which may result in the secretion of substances capable of influencing in a more general way the tone of unstriated muscles, and of acting by this indirect mechanism on the humoral agents of the autonomic nervous system.

These results, however, do not explain why the same transmitter, adrenalin, causes the uterus of the rabbit to contract and the uterus of the guinea pig to relax, that is, of animals of the same species presenting analogous hormonal levels. We therefore administered a small dose of adrenalin to the isolated rabbit uterus and transferred, after contact varying from 15 to 40 min., the surrounding fluid to an isolated guinea pig uterus. This fluid produced a contraction of the guinea pig uterus which originally reacted to the administration of adrenalin with relaxation. The effect is not reciprocal in character; fluid obtained after the action of adrenalin on the guinea pig uterus still has a contracting effect on a rabbit uterus. On the other hand, when the fluid containing adrenalin after having been in contact with the rabbit uterus is transferred to the isolated intestine, it causes the usual inhibitory action of adrenalin on that organ, and a fluid containing adrenalin after having been in contact with the small intestine continues to produce contraction of the isolated rabbit uterus.

These findings suggest the presence of a special agent in the rabbit uterus conditioning the paradoxical action of adrenalin on that organ. They suggest in a more general way that the biological analysis of isotonic liquids which have been in contact during various periods and under various conditions with isolated organs may constitute a profitable method for the study of the behaviour of effector cells.

A Nemestrinid Parasite of *Schistocerca gregaria* (Forsk.)

During dissections of an immature male specimen of the desert locust, *Schistocerca gregaria* (Forskål), a yellowish larva of Nemestrinidæ was found feeding on the testes and the surrounding adipose tissue. It was 1 cm. long. Its posterior end was surrounded by a chitinous cup leading to a slender respiratory tube *c.* 2 cm. long, which was constricted transversally along its whole length (these constrictions disappear when pressed during the preparation). The respiratory tube went longitudinally along the midgut and then was bent at right-angles towards the spiracle of the first abdominal segment. The tube was more or less uniform in width, becoming dilated at the cup surrounding the posterior spiracle of the larva. The end of the tube entered the meeting place of the tracheæ, which was considerably expanded. The chitin of this end was blackish-brown, due to pathological changes.

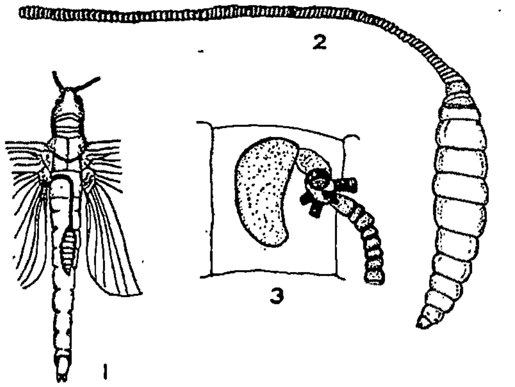

Fig. 1. *Schistocerca* dissected showing the Nemestrinid larva with the respiratory tube. ⅓ Nat. size
Fig. 2. Nemestrinid larva with the respiratory tube. × 3
Fig. 3. The spiracle, tympanal organ and the respiratory tube shown from inside

Potgieter[1] has described a Nemestrinid *Simmictus costatus* (Lw.) developing inside the body of *Locustana pardalina* (Wlk.) in South Africa. Noble[2] described larvæ, pupa and adult of *Trichopsidea œstracea* (Westw.) from *Chortoicetes terminifera* (Wlk.) in Australia. Fuller[3] has given a full description of *Trichopsidea œstracea* (Westw.) on various grasshoppers there. Crouzel and Salavin[4] described in detail two species of *Neorhynchocephalus*, *N. sulphureus* (Wied.) and *N. vitripennis* (Wied.) parasitizing the Acrididæ *Trigonophymus arrogans* Stal. and *T. elongatus* Giglio-Tos.

Unfortunately, our larva remained unidentified, as the attempt to transfer it into the body of another grasshopper failed. According to Dr. B. P. Uvarov (in correspondence), this is the first record of a Nemestrinid parasite of *Schistocerca gregaria*. I wish to express my thanks to Dr. Uvarov for his help and criticism in the preparation of this note.

Antiquity of Man in Australia

For nearly eighty years, one of the most prominent items of anatomical evidence in support of the antiquity of man in Australia has been a fragment of a supposed human molar, found by Krefft in the Wellington Caves of New South Wales.

Early doubts expressed as to the value of its evidence were based on the possibility of its adventitious presence in the caves. These doubts were afterwards dispelled by eye-witnesses, and it is now accepted that the tooth, when found, was imbedded in the characteristic cave breccia, together with remains of *Diprotodon* and *Thylacoleo*. According to the estimate of Sir Edgworth David in 1923, the association dates back to a period 7,000–12,000 years ago.

The fossil has been discussed by Krefft (1870–74), Etheridge (1890–1916), David (1923) and Anderson (1933), all of whom have accepted its human origin.

Recently, the human origin of the fragment has been questioned by Dr. T. D. Campbell, and I have considered *de novo* its possible relation to the lower mammals. To this end, the morphology of the fragment and the type and sequence of the attrition which have produced its crown pattern have been minutely compared with all indigenous Australian mammals, with all introduced and domestic mammals, and with many exotic species as well, which could possibly yield a dental fragment of the size of the fossil. Three chief results have accrued from this examination.

(1) The fossil is derived from a tooth possessing extreme functional brachydonty. At the same time, the occlusal surface exhibits large exposures of dentine in juxtaposition with broad enamel structures. While both features may be separately found in the molars of a few mammals, their concurrence in the same species is generally precluded by the structural ground-plan of the tooth. Consideration of this fundamental peculiarity of the fossil early led me to abandon the view that it was a molar tooth at all.

(2) On transferring attention to premolar teeth, close analogies in structure were soon found to exist between the fossil and the third and fourth premolars of the Macropodinæ, in an advanced stage of wear. In particular, the highly characteristic pattern of the occlusal surface of the fossil is very closely reproduced in the premolars of the black-tailed wallaby (*Macropus walabatus* L. and G.), and a study of the successive stages of attrition through which such teeth have passed correlates in the clearest way all the main structures of the fossil, with their originating centres in the unworn premolar.

(3) After direct comparison with relevant material, and with the above general conclusions as a guide, I have no doubt that Krefft's find was derived from the posterior half of the upper fourth premolar or seccator, of the right side, of *Macropus* (*Protemnodon*) *anak*, Owen, a giant Pleistocene 'wallaby', remains of which are already known from the caves, and which occur also in profusion in beds of similar and earlier age over a wide area of eastern and south-eastern Australia.

A detailed, illustrated account will follow.

Origin of the Golden Hamster *Cricetus auratus* as a Laboratory Animal

The golden (Syrian) hamster *Cricetus auratus* is now being bred in scientific institutions in Europe and America and has proved useful for various experimental investigations. Workers from different countries have written to me inquiring about the origin of the golden hamster, which is now widely distributed in many laboratories. Some of the correspondents are interested in using *Cricetus auratus* for genetics, others in the history of this hamster as a laboratory animal.

In 1930 the late Prof. Aharoni, of the Department of Zoology of the Hebrew University, Jerusalem, went on a zoological expedition to Syria (he was particularly interested in the fauna of Antioch). We were engaged on investigations for the Royal Society on Mediterranean kala azar, and the only suitable experimental animal then known was the Chinese hamster, which had to be imported from the Far East and had the additional disadvantage of not breeding in captivity. Stocks could only be replenished by importing, and lengthy experiments in the Middle East were imperilled by epidemics of *Pasteurella* to which this animal is very susceptible.

Prof. Aharoni undertook to bring specimens of *Cricetulus phœus* for our work. In addition to specimens of *Cricetulus phœus* (which were also unsatisfactory because they did not breed in captivity), Prof. Aharoni brought back a litter of eight golden hamsters collected near Aleppo which he reared and presented to the Department of Parasitology in July 1930.

Four of the animals escaped, one female was killed by a male and only three animals—one male and two females (all litter mates)—remained. From these three animals Mr. H. Ben Menahem succeeded in raising litters, and it was quickly established that this species breeds readily in captivity. It was first used for investigations on kala azar in November 1930, and was afterwards found valuable for work on tuberculosis and brucellosis. As soon as this was realized, I decided to distribute the animal as widely as possible and avoid the risk of maintaining a valuable species in one laboratory. (The animal is very susceptible to *S. typhimurium*, and wherever there is a danger of contamination with this *Salmonella*, it is advisable to vaccinate.) I brought specimens to the Collège de France (Prof. Nattan Larrier), to the Medical Research Council and to the Wellcome Bureau of Scientific Research, where Dr. E. Hindle succeeded in breeding them. Shortly before the Second World War I sent animals to India for kala azar research, and the late Prof. I. J. Kligler sent a batch to America. I also sent several batches recently to Egypt. During the War, animals infected with kala azar were sent to the United States at the request of the American Army authorities for experiments on chemotherapy; but these animals were probably not used for breeding.

To the best of my knowledge all the golden hamsters now in use as laboratory animals in Europe and America originate from the above-mentioned three litter mates—one male and two females brought to the Department of Parasitology of the Hebrew University of Jerusalem in July 1930.

It would be interesting to collect more wild specimens from the neighbourhood of Aleppo, and I hope that some worker favourably situated for this purpose will succeed in doing so.

Determination of Plant Densities

IN surveying plant associations, it is usual to determine the valence by noting the presence or absence of each species in sample areas, and the density by counting the number of individuals of each species in the same, or other, sample areas. Two difficulties are frequently encountered in determining densities by this method, the length of time needed in the field and the intermingling of root systems of individual plants of the same species with consequent indecision as to the exact number present in the sample. The following method has the advantage of requiring one set of observations only, from which valence and density may be determined, and of avoiding counts within the sample areas.

Suppose the species has a density N/A plants per unit area and that a sampling area a is taken t times at random. Then the expected number of plants per trial will be aN/A, and the number y_0 of trials containing no individuals of the species would be expected to be given by the expression

$$y_0 = t \exp(-aN/A).$$

$$\text{Whence } \frac{N}{A} = \frac{1}{a} \cdot \log_e \cdot \frac{t}{y_0}.$$

If the number of trials is 50 and the sampling area 0·1 square metre, a graph relating density and y_0 can be drawn and shows a remarkable sensitivity for densities 33 per sq.m. to 3 per sq.m. By increasing the sampling area to 1 sq.m., the density values on the graph are reduced ten times, and we have a sensitive range from 3·3 per sq.m. to 0·3 per sq.m.

Much time has been saved in the field and results are reasonably in accord with densities found by the more laborious method.

Metabolism of α : β-Dihydroxy-γ-(2-methylphenoxy)propane ('Myanesin')

IN a recent communication[1], Wyngaarden, Woods and Seevers have shown that 'Myanesin' administered intravenously to dogs appears in the urine mainly in combination with glycuronic acid, while a small amount is excreted without change. We have found that after intravenous administration to humans or rabbits, a portion is oxidized and excreted as α-hydroxy-β-(2-methylphenoxy)propionic acid. The acid may be isolated by acidifying the urine to *p*H 3, extracting with ether continuously for 24–48 hours, transferring from the ether extract into sodium bicarbonate solution and recovering from the aqueous solution by acidifying and extracting with ether. The ether-soluble product is crystallized first from carbon tetrachloride, then from water and finally from chloroform. The pure acid melts at 146–147° (corr.) (found: C, 61·2; H, 6·1; $C_{10}H_{12}O_4$ requires C, 61·2; H, 6·1 per cent). The acid is not optically active. It is identical with the acid obtained by condensing *o*-cresol with β-chlorolactic acid (found: C, 61·1; H, 6·1 per cent).

We are indebted to Dr. F. Barnett Mallinson for supplies of urine from patients who had received 'Myanesin'. Our thanks are also due to the directors of the British Drug Houses, Ltd., for permission to publish this note.

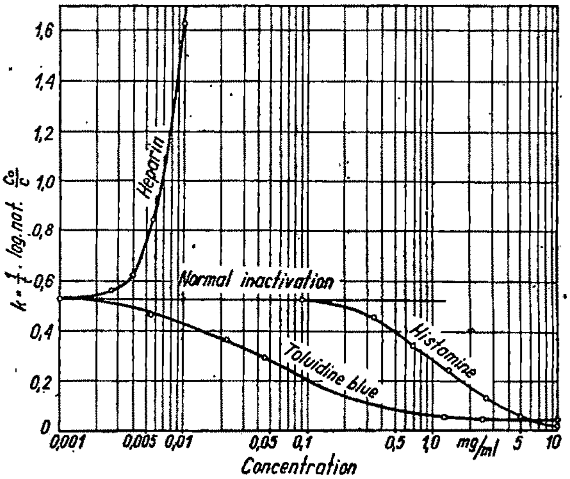
Histamine – Heparin – Thrombin Chain Mechanism

EARLIER experiments of ours have shown that the organism regulates the coagulability of the blood by the inactivation of thrombin[1,2]. Many factors take part in the system causing the thrombin to disappear. We distinguish an adsorption effect and a fermentative inactivation process, and indicate the inactivating process by its reaction velocity factor.

We have worked out a simple and rapid process for investigating the inactivation[3]. We put thrombin of a known activity into the serum under investigation, and after an incubation period of 1, 2, 3, 5 or 10 min., we determine the time in which samples taken from the mixture make the fibrinogen coagulate. As a result of the inactivation we get increasingly longer clotting-times. From the clotting-times we determine their thrombin activity on the basis of an empirical relation, and from the data thus obtained we calculate the reaction velocity factor ($k = 1/t$ log. nat. co/c).



Change in thrombin inactivation reaction-velocity constant under the effect of heparin, toluidine blue and histamine respectively, in rabbit serum

Heparin increases the reaction velocity of the inactivation (see graph). If we bind the heparin with toluidine blue, the velocity of the inactivation diminishes decidedly[4]. We find that histamine, both *in vitro* and *in vivo*, likewise strongly decreases the inactivation, and thereby shifts the clotting capacity of the blood towards coagulation[5]. We have also shown that histamine and heparin bind one another, and have obtained a colour reaction from this[6].

As histamine and heparin are both constantly present in the blood in physiological circumstances, it must be supposed that the normal coagulability of the blood is regulated intravasally by histamine – heparin equilibrium. If this equilibrium shifts towards histamine there is a diminished inactivation and the blood coagulates better, which in certain cases can lead to intravasal fibrin precipitation. But if there is a preponderance of heparin the effect of the inactivating system increases and the blood does not clot so well. These phenomena have been thoroughly observed in pathological[7,8] and experimental[2,9,10] conditions.

Jancsó demonstrated in 1931 that a preliminary condition for the accumulation process of reticulo-endothelial systems was that the colloids to be eliminated from the blood are enclosed in a covering of fibrin, and that this colloid-fibrin complex becomes attached to the endothelium[11]. It was later also found that this occurs also as an effect of histamine[12]; but intermediate links in the chain were lacking to explain how, as an effect of histamine, the fibrin appears in the blood.

But on the basis of the foregoing, the route of the chain mechanism would appear to be briefly that histamine is produced as an effect of the foreign substances introduced into the blood. This binds the heparin and thus inhibits the inactivation of thrombin. This in turn leads to the formation of thrombin and causes intravasal fibrin precipitation. The precipitating fibrin carries off the colloids, which attach themselves to the walls of the endothelium, where their phagocytosis begins. When this phenomenon has taken place, the increasing liberation of heparin compensates for the increased clotting capacity of the blood.

On this basis, the physiological sphere of thrombin must be extended. The function of thrombin is not only to bring about extravasal clotting, but also to fulfil an at least equally important task intravasally, in starting the accumulation in the reticulo-endothelial system as one of the links in the chain of the whole process. This also throws a new light on the problem of thrombosis. Thrombosis occurs when the organism cannot, by increased liberation of heparin, restore to normal the lowered thrombin inactivation required for colloid accumulation.

Hæmoglobin – Methæmoglobin Mixtures

WE[1] have recently had an opportunity of confirming, in a case of familial methæmoglobinæmia, the shift to the left in the oxygen dissociation curve of hæmoglobin which Darling and Roughton[2] found in hæmoglobin – methæmoglobin mixtures. They suggest that the shift in the curve may be explained by the existence of intermediate compounds, the affinity of which for oxygen is greater than that of hæmoglobin. On this assumption, the formation of methæmoglobin from hæmoglobin does not take place in a single step; but the four iron atoms of the hæmoglobin molecule may be oxidized separately and successively. If the iron in the hæmoglobin (or oxyhæmoglobin) molecule is represented as $(Fe^{++})_4$, the iron in the intermediate mixed molecules would be $(Fe^{+++})(Fe^{++})_3$, $(Fe^{+++})_2(Fe^{++})_2$, $(Fe^{+++})_3(Fe^{++})$, and that in methæmoglobin itself $(Fe^{+++})_4$. As the shift in the dissociation curve is fairly large, it is evident that quite appreciable amounts of the intermediate compounds would be present in methæmoglobin – hæmoglobin mixtures, and might afford spectroscopic evidence of their presence. Apart from its theoretical interest, the question is of some practical importance, for alterations in the absorption spectrum due to this cause would necessitate modifications in the estimation of blood methæmoglobin made by optical methods, for example, that of Evelyn and Malloy[3].

We have looked for spectroscopic evidence for the presence of the intermediate compounds by making differential measurements of the absorption at the red end of the spectrum (where methæmoglobin shows a strong absorption band), comparing optical and physical mixtures of hæmoglobin and methæmoglobin in a Spekker absorptiometer. Using two pairs of closely matched 1-cm. cells, we first filled one member of each pair with a definite volume of methæmoglobin solution containing 1 gm./100 ml. pigment. (The solution was prepared from toluene-laked, washed ox erythrocytes by the action of a small excess of sodium nitrite. It was filtered and exhaustively dialysed at 4° in a rocking dialyser and diluted with *p*H 7·4 phosphate buffer.) The other cells were filled with the same volumes of a separately dialysed, filtered and buffered solution containing 1 gm./100 ml. oxyhæmoglobin. Each oxyhæmoglobin-containing cell was then examined in conjunction with a methæmoglobin cell.

The difference in optical density between the pairs of cells (using 2 mm. Hilger red No. 1 and 2 mm. Calorex filters) was 0·002, representing the difference between the pairs of glass cells. On mixing the contents of one pair of cells, to give a 50 per cent mixture of oxyhæmoglobin and methæmoglobin, the change in absorption was not greater than 0·001, nor was any further change found in readings taken up to 18 hr. after mixing. The total absorption under the conditions used was 0·805, so that the change on mixing was less than 1 in 500 of the total absorption, that is, well within experimental error. Examination of the solutions (diluted 1 in 5) with the Hartridge reversion spectroscope also failed to show any difference between the optical and physical mixtures in the position of the methæmoglobin band in the red part of the spectrum.

If the explanation of Darling and Roughton for the shift in the dissociation curve is correct, it would appear, therefore, that the absorption spectrum of hæmoglobin derivatives is determined not by the molecule as a whole, but by the sub-molecules containing one iron atom.

Crystal Structure of Nitronium Perchlorate

We have made an X-ray examination of the nitronium perchlorate of Goddard, Hughes and Ingold[1] and find, in agreement with Millen's observations on its Raman spectrum[1], that the crystal structure contains the ions NO_2^+ and ClO_4^-.

The crystals are monoclinic, the unit cell having dimensions $a = 9{\cdot}25$ A., $b = 6{\cdot}99$ A., $c = 7{\cdot}34$ A., with $\beta = 113{\cdot}5°$, and containing four molecules of $NClO_6$. The existence and general arrangement of the ions was discovered from two-dimensional Patterson syntheses of the intensities of X-ray reflexions in the three principal zones, and confirmed by comparison of observed and calculated structure amplitudes; the chlorate and nitronium ions are arranged alternately along twofold axes, in accordance with the space group $C\ 2/c$, the nitrogen and chlorine atoms lying on the twofold axes, with all the oxygens in general positions. By using $\{hkl\}$ structure amplitudes in sectional projections[2] we find that the NO_2^+ ion is linear with N—O $\sim 1{\cdot}1$ A., and the ClO_4^- ion approximately tetrahedral, with Cl—O $\sim 1{\cdot}5$ A. Successive Fourier refinement is now being applied to obtain more accurate values of these bond-lengths.

We are indebted to Prof. C. K. Ingold and Mr. D. R. Goddard for providing crystals specially prepared for this work.

Emissivity of Small Particles in Flames

It is a striking fact that solid (or massive) carbon behaves as a black body, whereas small carbon particles which are responsible for the luminosity of hydrocarbon flames have an absorption coefficient which is strongly dependent on wave-length. This difference is important in the measurement of the colour temperature of luminous flames. It has been shown theoretically by Mie[1] that the absorption coefficient is strongly dependent on wave-length when particles are smaller than a wave-length, an effect which is analogous though not identical with the dependency of scattered light on wave-length.

We have made some optical measurements on a stationary flame of aluminium flakes in air. These experiments differed from the often repeated measurements on photo-flashes since the flame had a greater depth (5–10 cm. diameter). The intensity distribution in the flame was unusual. The radiation consisted of weak AlO bands and a strong continuum which extended from the red far into the ultra-violet regions. The colour temperature was about 3,600° C. It may be shown theoretically that the enthalpy of the exhaust gases permits the temperature of the flame to reach the boiling point of aluminium oxide (Al_2O_3), which is 2,980° ± 60° C., and that nearly all the oxide is vaporized. When we threw an image of the anode of the carbon arc on to the aluminium–air flame, we observed very weak absorption in the visible and increasing absorption towards the violet region. At 3100 A. all light from the arc was absorbed. The emission coefficient, therefore, became very nearly equal to unity in the ultra-violet. By comparing the brightness of the flame at 3100 A. with the brightness of the carbon arc anode, we estimated a brightness temperature which was a little below the calculated (theoretical) temperature. Line reversal measurements (ordinarily a little high on account of the scattering effect) gave a slightly greater value than the calculated temperature.

The close agreement of these results satisfied us that the temperature of the flame was actually the boiling point of aluminium oxide. If we adopt this value, however, an explanation is needed for the high colour-temperature observed, or in other words, for the strong dependency of emissivity on wave-length. We believe that most of the aluminium oxide formed in the flame is initially in the gaseous state. The radiation may therefore originate from gaseous aluminium oxide or other gaseous products (excited thermally or by chemiluminescence), but no continuum of gaseous origin is known which extends so far. Moreover, it is perhaps significant that the conditions are very similar to those in the luminous hydrocarbon flame, where emission is undoubtedly due to small particles.

We suggest, therefore, that small droplets of aluminium oxide are the emitters in the aluminium flame, and that these particles are formed by condensation in the flame. Produced in this way, the particles are finely dispersed and very small. Their temperature is identical with the gas temperature, even if catalytic reactions occur on the surface, because the heat transfer numbers of such particles are extremely high. Some of these particles are no doubt smaller than the wave-length of light (Shechter *et al.*[2] have produced evidence of this), and the absorption and emission characteristics of such particles will behave in the same way as radiant soot. The abnormally high colour-temperature is again attributed to the optical properties of very small particles. Moreover, the colour temperature depends upon the thickness of the optical layer, because the thicker the layer the more the radiation will approach black-body conditions.

Magnesium behaved in a similar manner.

Application of Measurements of Semi-conductivity to Heterogeneous Reactions

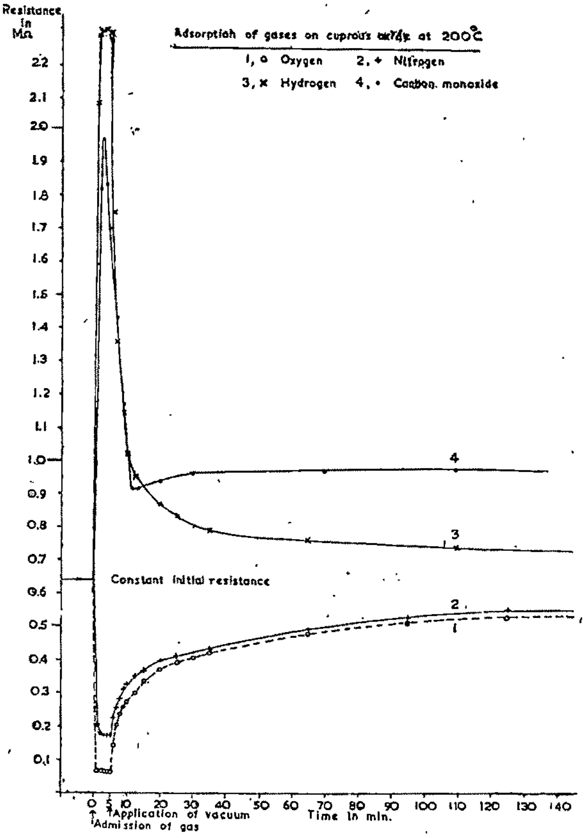
In the present investigation pure oxide films are obtained by the oxidation of evaporated metal films. Normal high-vacuum precautions are observed in the use of all-glass, greaseless systems with precise temperature control. The method of investigation which has been developed is based on the semi-conducting properties of these oxide films. Simultaneous pressure and resistivity measurements are made during the adsorption and desorption of various gases on the oxide films over a range of temperatures between 0° and 250° C. While variations in conductivity of bulk semi-conductors on exposure to air have been previously observed and reported (Anderson *et al.*), the effect has not previously been applied to the problem of catalysis. Preliminary investigations which have been carried out on copper oxide films have demonstrated the efficiency in obtaining reproducibility of the film during periodic oxidation and reduction.

On oxidation of the copper film during the initial period of oxidation the resistance measurements are effectively those of the residual copper layer, being of the order of one ohm in typical cases. This period is characterized by a parabolic uptake of oxygen. At the end of this period, which occupies several hours at 200° C., there is an extremely rapid change in resistance over a period of a few minutes before stabilizing at a high value, 350 k.ohm in a representative case. After this there is a slow exponential change in resistance to a final value corresponding to that of pure cupric oxide obtained after approximately 25,000 min. at 200° C. In this final state the film shows no increase in resistance on sustained pumping at 10^{-7} mm. mercury pressure.

On hydrogen reduction there is an induction period, after which the resistance increases to a very high maximum value, corresponding to the formation of cuprous oxide in the non-conducting state. Further reduction gives a rapid fall in resistance to a value of about 50 k.ohms in a typical case, at which point erratic readings are obtained, fluctuating between that value and a few hundred ohms. This continues for a period of about 15 min. and corresponds to the embrittlement phenomenon reported by Garner and Stone[1], probably due to the escape of water from the film. After this characteristic period the resistance falls exponentially until after about 30,000 min. the original resistance of the copper film is obtained.

For studying the effects of adsorbed gases, the films were employed in the semi-conducting region corresponding to a stoichiometric ratio lying between cuprous oxide and cupric oxide. When the film had been oxidized to the required composition it was subjected to prolonged pumping at 10^{-7} mm. mercury pressure, during which there was an increase in resistance to a constant value, 650 k.ohms in a typical case. The value of this maximum corresponds very closely to the final value of the pure cupric oxide film and did not vary significantly over a wide range of composition. This corresponds with the observations of Anderson and others on the effect of the evacuation of bulk semi-conductors.

Quantitative and qualitative information has been obtained concerning the effect of the adsorption of oxygen, nitrogen, hydrogen and carbon monoxide on the semi-conducting films in this condition. Admissions of oxygen at a series of temperatures and at pressures varying between 10^{-3} mm. and 0·3 mm. mercury pressure have shown that there is an immediate fall in resistance of great magnitude taking place within the first five seconds, followed by a slightly slower change over a few minutes (curves 1 and 2). The films are only exposed to the oxygen for a few minutes and are then subject to hard vacuum, 10^{-7} mm. pressure being attained in approximately 15 sec. During evacuation there is an increase in resistance, a very rapid second-order change at first, but becoming exponential after about 30 min. The final value obtained after about 2,500 min. is, for temperatures above 200° C., identical with the initial value; but below this temperature very protracted pumping fails to re-establish the original equilibrium condition. All curves show a very high degree of reproducibility.



The effect of nitrogen is qualitatively the same as for oxygen, while helium, which has no effect alone, modifies the effect of both adsorption and desorption by slowing down both processes to a marked degree.

On the adsorption of carbon monoxide or hydrogen the resistance increases rapidly to a very high value (curves 3 and 4). In the case of hydrogen the process is reversible, but in the case of carbon monoxide the removal of the gas, possibly as carbon dioxide, is complicated by the apparent immediate reduction and sintering of the surface, which completely alters the film characteristics. After adsorption of carbon monoxide it is possible to return the film to its standard state only by oxidizing the film completely, reducing to copper and reoxidizing. Only after this drastic processing does the film reproduce earlier results. This effect has been reported by Garner and Stone on bulk copper oxide.

The investigation is being extended to a range of temperatures enabling temperature coefficients of the various processes to be established, and to various other oxides. Precision measurements of gas adsorbed and desorbed are being introduced, and the significance of substrate is being investigated.

Although too early to embark on any rigid theoretical consideration of the significance of the results, it is clear that providing the general picture of semi-conduction as given by Mott is accepted, then these measurements must yield direct information of the nature of the catalytic processes occurring, as related to adsorbed gases on semiconducting oxide catalysts.

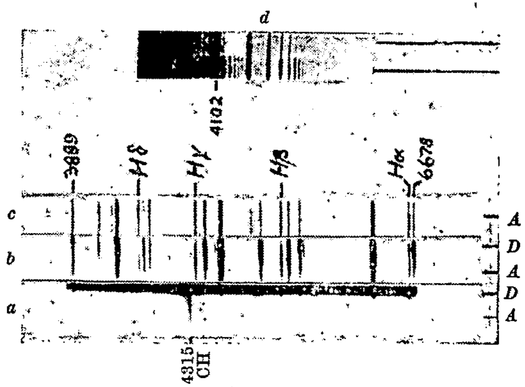
Afterglow of the Balmer Spectrum of Hydrogen

IN a paper published during the War the late Lord Rayleigh reported some new experiments about the hydrogen spectrum, indicating a duration of Balmer lines of more than 10^{-5} sec., which is roughly one thousand times greater than the values calculated from quantum mechanics and experimental results with positive rays. The method consists in producing a strong luminosity induced by a powerful condenser discharge in an electrodeless glass tube. Each discharge produces a jet of luminosity, squirting out of the electric field by thermal expansion into a side tube where the decay of the Balmer lines is observed and measured[1].

Lord Rayleigh did not attempt any explanation of this result and apparent discrepancy. Jablonski has remarked that the mean duration of lines is not always identical with the mean life in initial states of corresponding transitions. After having considered the various mechanisms which can produce atoms in the upper level, he thinks that the persistence of the luminosity results from the radiative recombination of atomic hydrogen ions[2].

Born, Fürth and Ladenburg[3] prefer to believe that Lord Rayleigh's experiments can be understood on the basis of the known relatively long life of free hydrogen atoms and their re-excitation "by radiation and, especially, by the diffusing electrons and positive ions". The rise of the relative intensity of the blue-green H_β lines (4861 A.) observed by Lord Rayleigh with decreasing luminosity is ascribed to the sensitivity of the eye, which has a maximum in the green part of the spectrum.

In view of making a choice between the two above interpretations, new experiments were performed on the hydrogen afterglow. The experimental arrangement is the same as already described[4]. It permits a careful separation of the light of the discharge from that of the afterglow one. The excitation energy used in our experiments is weak and is not sufficient to show the persistence of the luminosity in pure hydrogen. But when this element is diluted in neon or helium a strong afterglow can be observed. In the case of helium, traces of hydrogen almost always present are sufficient to give the phenomenon. Other impurities like CO and CH destroy the afterglow: the spectrum *a* shows that only the band 4315 of CH persists in this case. The impurities are eliminated either by producing a powerful discharge between two magnesium electrodes or by immersing the discharge vessel in liquid nitrogen.



D, discharge ; *A*, afterglow

Spectrum *b* shows the modification of the emission of helium containing traces of hydrogen when the discharge is cut off. The Balmer lines suffer less variations than He I lines, and the relative intensity of H I increases with time. This later variation can be seen easily by comparing the spectrum at the beginning of the afterglow with spectrum *c* emitted 10^{-3} sec. after breaking the discharge. The duration of the lines increases with the quantum number *n* and the intensity of distribution of the Balmer spectrum varies with time (compare spectra *b* and *c*).

By measuring the decay of luminosity with the time, we have evaluated the duration of the H_γ line at 10^{-4} sec. after breaking the discharge.

It is possible to show that the emission in question follows the capture of electrons by ions by studying the afterglow at the limit of the Balmer series. The discharge and the afterglow were photographed in the ultra-violet region with an Arnulf – Lyot spectrograph. The results are illustrated by the spectrum *d*. In the afterglow, the hydrogen spectrum is extended further than in the discharge; at the same time, the higher level lines of He I grow in intensity.

The above results, although they do not allow a direct comparison with Lord Rayleigh's experiments, show that hydrogen atoms can radiate the whole Balmer series in afterglow. The persistence of the lines at the limit of the series seems to be conclusively in favour of an emission by radiative recombination between ions and electrons.

Decay Scheme of ^{181}Hf

IN continuation of our previous analysis of the decay scheme of ^{181}Hf [1], we have carried the work further with higher resolving power and using a spectrometer with a thin Geiger–Müller window. We have also carried out delayed coincidence measurements to study the metastable state reported by De Benedetti and McGowan[2]. We have attempted to eliminate various possible decay schemes which have been proposed[1-3], in favour of one to be discussed here.

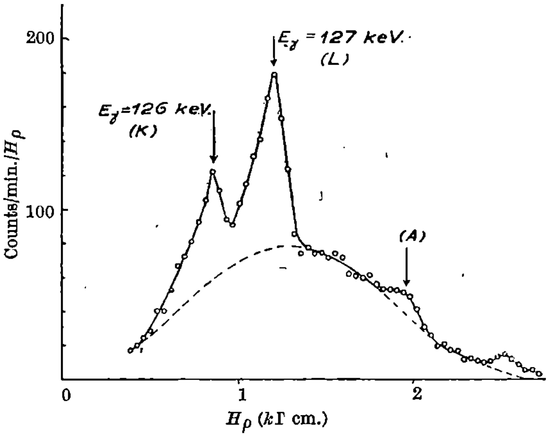

Fig. 1. The β-spectrum of ^{181}Hf (resolving power 4 per cent)

The measurements of the β-spectrum were repeated with the same spectrometer as formerly[1]. The resolving power was, however, increased to 4 per cent and the window thickness reduced to $\sim 0\cdot5$ mgm./cm.^{2}. The β-spectrum is shown in Fig. 1. It will be seen that the conversion line (A) of the 342-keV. γ-quantum which could not be discerned in the previous measurement now appears distinctly. Otherwise the two spectra are in good agreement.

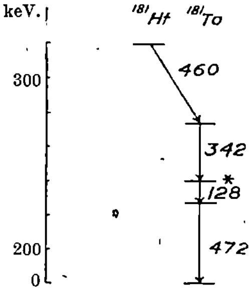

Fig. 2. Decay scheme of ^{181}Hf (all energy values given in keV.)

Delayed γγ-coincidence measurements were carried out in our standard arrangement[1], where a time-delay of $\sim$ 10 μsec. was introduced in one channel. The sample was enclosed in a lead shield 1 mm. thick. The soft radiations (the unconverted 128-keV. γ-quantum and the corresponding X-radiation) were thus practically cut off. Under these conditions, a γγ-coincidence effect amounting to $(k_{\gamma\gamma}/n_\gamma) \times 10^3 = 7 \times 10^{-3}$ was found. This effect is about half the chance coincidence effect. The experiments were repeated many times, and the chance coincidence effect was checked, after each measurement, by ^{60}Co of the same counting-rate in the tubes. These results support the decay scheme given in our previous paper[1] and reproduced here in Fig. 2. The magnitude of the coincidence-rate is in agreement with that computed (from the geometry of the arrangement, the efficiency of the γ-tubes, the half-life of the metastable state and the delay and resolving times of the amplifier).

According to the conclusions of De Benedetti and McGowan[2] the metastable state should follow directly the β-transmission. This is not in agreement with our suggestion. The reason why they have not found any effect of the γ-ray which precedes the metastable state may be due to the fact that its energy is less than the one which follows the metastable state.

Errors of Treatment Comparisons when Observations are Missing

In a randomized block experiment with J blocks and K treatments, for which σ^2 is the variance of the random component of the observations and for which no observations are missing, the estimated difference of the means of two treatments has variance $2\sigma^2/J$. For the case where some observations are missing, Yates[1] has shown how the missing values may be estimated, a valid analysis of variance carried out, and an unbiased estimate of the difference of means of two treatments obtained. He has given the variance of this estimate for the case of only one missing observation, and has suggested an approximation for use in other cases which may be expressed as follows.

If J_A observations are present for treatment A, and j_A of these are in blocks which contain no observation for treatment B, and if J_B observations are present for treatment B, and j_B of these are in blocks which contain no observation for treatment A, then the variance of the estimate of the difference of means of A and B is $\theta_{AB}\sigma^2$, where

$$\theta_{AB} = \frac{1}{J_A - \frac{1}{2}j_A} + \frac{1}{J_B - \frac{1}{2}j_B}; \text{ approximately.}$$

I have derived exact formulæ for θ_{AB} for all cases where not more than three observations are missing, and have compared the exact and approximate values for a wide range of values of J and K. The agreement is reasonably good when K is small but poor when K is large. The formulæ suggest that a closer approximation would be given by

$$\theta_{AB} = \frac{1}{J_A - \dfrac{1}{K-1}j_A} + \frac{1}{J_B - \dfrac{1}{K-1}j_B},$$

and this is confirmed by numerical calculation. If not more than three observations are missing and J and K are both greater than 3, the error of the approximation only exceeds 4 per cent in a very few cases. These all occur either where there are three missing observations and $J = K = 4$, or where practically all observations of one treatment or one block are missing. In most cases the error is very much smaller than this.

In practical applications an analysis of variance would first be carried out to test if there were any significant differences between treatments. If so, any pair could be tested and would be judged to differ significantly if the difference of their means exceeded $t\sqrt{\theta}\,s$, where s^2 was the error mean square with n degrees of freedom, and t was the appropriate percentage point of the t-distribution with n degrees of freedom.

Development of Spark Discharges

IN a recent communication[1] concerning the mechanism of growth of the leader strokes preceding spark discharges, Allibone has stated that the leader stroke develops behind a voluminous corona discharge and that the concentrated bright streamer, which is readily photographed, is in the nature of a 'core' to this corona. The same view has been expressed by ourselves on various occasions and in earlier reports[2], and not only have we succeeded in demonstrating beyond doubt the existence of this diffuse corona discharge forming the head of the leader stroke, but we have also been making extensive investigations of its characteristics during the past eighteen months.

From consideration of the rotating camera records[3], which show the existence of diffuse corona discharges in association with the brighter filamentary streamers, it became clear to us some time ago that the photographic methods of observing the development of leader strokes have certain limitations and require to be supplemented by other techniques[4]. Allibone has referred to experiments made with Lichtenberg figures, but in such measurements, where stationary recording systems are used, it is difficult to determine the sequence of the processes observed, particularly because of the diffuse nature of the discharge. Similar difficulties occur in the interpretation of rotating camera photographs, where a distinction between spatial and temporal displacements is confused when the photographed object is diffuse.

Because of the various limitations of the photographic measurements, we decided to study the growth of leader strokes by arranging for the light emission from the discharge to fall on the sensitive cathode of a photomultiplier, the output from which is amplified and is reproduced on an oscillograph screen[5]. With this technique, a very high resolution in time is possible, of less than 10^{-7} sec., and the sensitivity to light is greater than that of a photographic emulsion. Further, the intensity of the light can be determined more accurately than in the photographic method, where there is a failure in the reciprocity law when light pulses of short duration are being recorded.

With this technique we have observed the corona discharge occurring in a discharge gap between a positive point and a negative plane, for impulse voltages below that required to cause breakdown. Under these conditions, for a 50-cm. gap in air at atmospheric pressure, the corona discharge produces a light pulse as shown in the oscillogram of Fig. 1. The corresponding current pulse in the gap is of the same shape. Both pulses rise to their peak amplitude in a time 5×10^{-8} sec. and decline to a small value after 4×10^{-7} sec. By the use of slits placed between the gap and the photomultiplier the light distribution with corona has been examined, and we have found that the light is emitted from a roughly hemispherical volume, with the positive point at the centre of the plane face of the hemisphere, which is parallel to the negative plane, and with the curved face directed towards the plane. The light intensity decays continuously with distance from the point.

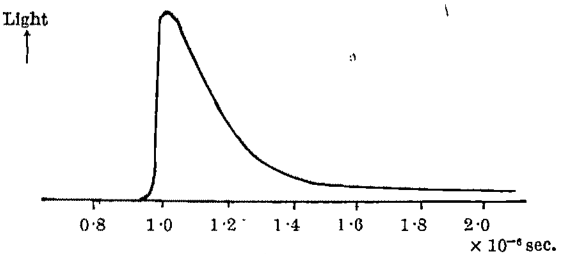

Fig. 1

When the impulse voltage applied to the gap is raised to the breakdown value, or to higher values, a leader stroke develops from the point and initiates a spark. The growth of this leader stroke has been studied by placing between the gap and the photomultiplier an opaque screen containing a slit, the position of which can be altered, so that changes of light in different parts of the gap can be recorded. As the leader stroke passes the slit it produces an increase in the light reaching the photomultiplier through the slit, and consequently a deflexion is produced on the oscillograph screen. The occurrence of the main stroke also causes a deflexion, and from measurements of the amplitude of the various deflexions and the time intervals, both the distribution of light in the leader stroke and its speed of growth can be determined. A typical oscillogram is reproduced in Fig. 2. The discharge commences as an impulse corona which is too small to appear on this oscillogram. Afterwards the light intensity passing through the slit increases gradually as shown to a peak which corresponds to the passage of the 'core' of the leader stroke across the slit. The light then decreases rapidly to a small value and increases again very suddenly when the main stroke occurs. From this evidence it is clear that the leader stroke does not consist of a point source, as this would give a sharp light pulse of duration about 10^{-7} sec., but that it is formed by a diffuse discharge which increases in intensity to a central 'core'. The distribution of the light in the leader stroke, and its size, is generally similar in appearance to the impulse corona mentioned above. Emission of light can be detected up to a distance of the order of 10 cm. ahead of the central 'core'.

Besides the measurements of the light distribution, in space and time, the speed of the leader stroke at different stages in its growth across the gap has been determined, and the current flowing in the leader stroke has been recorded oscillographically. The investigations have been made in air, at atmospheric

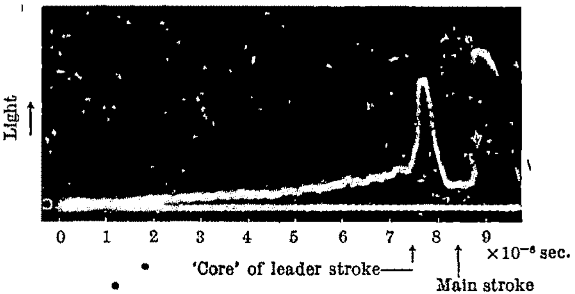

Fig. 2

and reduced pressures, and also in several other gases. A full account of these investigations will be published elsewhere.

[5] Prime and Saxe, *J. Inst. Elect. Eng.* (in the press).

THE object of my recent experiments[1] was to bring out photographically what we have known for many years. With an adequate background of visual observation of spark formation, there is no difficulty in determining in general terms the sequence of occurrence of the different kinds of discharge. As the voltage applied to a point/plane gap is increased, the corona extending therefrom increases (I would not have described the volume of discharge as hemispherical in shape; Fig. 5 in ref. 2 is a very typical shape for such a discharge), and near breakdown the concentrated bright streamers or leader strokes first become obvious extending over part of the gap as described in my communication in *Nature*[1]. The technique of chopping the spark with another spark gap in parallel enables the development of the leader stroke to be followed.

Prof. Meek and Mr. Saxe's technique will be invaluable in providing quantitative data on the corona and leader stroke currents and the light emitted by these discharges; but the facts they describe are well known though not well supported by photographs. The simple Lichtenberg figure technique which I have described gives the best photographic record of the leader stroke developing out of the corona discharge; it might even be more sensitive than the photomultiplier, because Fig. 2 of ref. 2 shows unmistakable evidence of corona one metre ahead of the leader stroke, whereas the multiplier has recorded light emission only 10 cm. ahead of the central core or leader stroke.

Internal Pair Conversion

WHEN a γ-quantum, emitted from the nucleus of a radioactive atom, is absorbed by the same atomic system, an ordinary electron and a positron may be liberated if the energy of the γ-quantum is greater than $2mc^2$. This effect has been calculated by Jaeger and Hulme[1] on the assumption that the γ-ray is electric dipole or quadrupole radiation. I have performed the corresponding calculation for the magnetic dipole radiation and the element $Z = 84$. In calculating the coefficient, Dirac's exact wave equation of the electron is used and the process is interpreted as the transition of an ordinary electron from a negative energy to a positive energy state. The results are given in the accompanying table, where the energies are expressed in units of mc^2 and N is the number of positrons (which is, of course, equal to the number of the pairs created) per unit energy range.

Energy distribution of the electron pairs

$h\nu = 2{\cdot}62$ MeV.	$\dfrac{E_+ - 1}{h\nu - 2}$	0·159	0·383	0·612	0·840
	$N(h\nu - 2)10^4$	7·10	9·70	14·9	26·2
$h\nu = 8{\cdot}00$ MeV.	$\dfrac{E_+ - 1}{h\nu - 2}$	0·073	0·366	0·635	0·926
	$N(h\nu - 2)10^4$	31·3	48·8	77·6	58·7

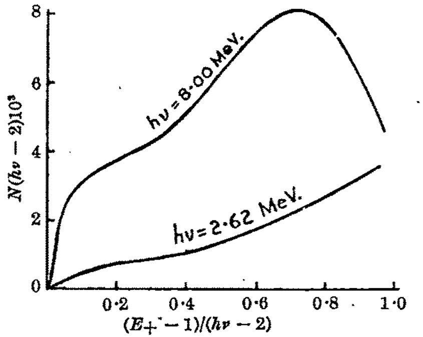

Fig. 1

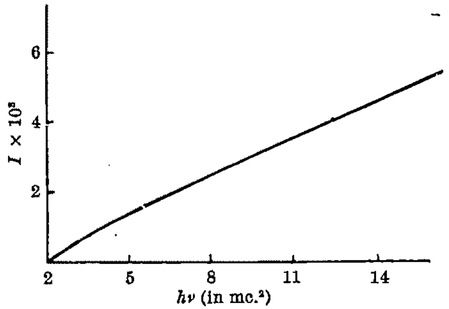

Fig. 2

In Fig. 1, $N(h\nu - 2)$ is plotted against $(E_+ - 1)/(h\nu - 2)$. The marked difference in the average energy of the electrons and positrons is due to the Coulomb forces acting on the two particles. Moreover, the curve, for $h\nu = 8{\cdot}00$ MeV., shows a maximum near the highest positron energy, as would be expected. By integrating over these curves, the coefficients of the internal pair conversion of the γ-rays are deduced. The results are:

$$I = 1{\cdot}5 \times 10^{-3} \text{ for } h\nu = 2{\cdot}62 \text{ MeV.,}$$
$$\text{and } I = 5{\cdot}6 \times 10^{-3} \text{ for } h\nu = 8{\cdot}00 \text{ MeV.}$$

If we plot I against $h\nu$ (Fig. 2), it is found that a straight line connecting these two points nearly passes through the point ($I = 0$, $h\nu = 2mc^2$).

In conclusion, I want to express my gratitude to Mrs. B. Jeffreys and Dr. N. Kemmer for their valuable discussions.

ISOLATION FROM ARGEMONE OIL OF DIHYDROSANGUINARINE AND SANGUINARINE: TOXICITY OF SANGUINARINE

By S. N. SARKAR
Department of Biochemistry, Oxford

ARGEMONE oil has received considerable attention during recent years on account of its alleged etiological role in epidemic dropsy[1-4]. I pointed out[5] certain anomalies of the mustard oil – argemone oil theory of epidemic dropsy and stressed the fact that a definite solution of the problem could only be arrived at by isolating the active principle from argemone oil and the suspected mustard oil, and then showing that these are chemically identical and possess similar toxic properties. Lal *et al.*[2] could not produce any satisfactory evidence on this aspect of the problem.

In a report of some preliminary work done, Sarkar and Rahman[6] stated that it was possible to precipitate the nitrogenous bases present in argemone oil as crystalline picrate, and from the crude picrate at least two fractions could be separated each of which when converted into the hydrochloride proved toxic to rats by oral administration, causing heavy mortalities. With the view of clearing up some of the important points, a detailed investigation was undertaken by me under the direction of Prof. R. A. Peters, and the relevant findings are reported here.

The main alkaloid of argemone oil has been purified by chromatographic analysis on an alumina column followed by crystallization from alcohol – benzene mixture. The purified compound (I), m.p. 190–91°, agreed in formula and properties with dihydrosanguinarine (found: C, 72·11: H, 4·54; N, 4·22; $C_{20}H_{15}O_4N$ requires C, 72·07; H, 4·51; N, 4·21 per cent). It is clear, therefore, that the formula $C_{19}H_{15}O_4N$ proposed for this compound by Mukherji, Lal and Mathur[7] is not correct. An authentic sample of dihydrosanguinarine obtained from the laboratory of the late Prof. Späth, when further purified by the present procedure, melted at 190–91°, and the mixed melting point with compound (I) did not show any depression.

Compound (I) could be readily oxidized by ferric chloride in presence of hydrochloric acid giving beautiful orange-red crystals of sanguinarine hydrochloride (II). This compound is identical with the compound obtained before in the ferric chloride test for the detection of argemone oil developed by me[8]. By the identification of the compound, the theoretical basis of the test is provided. Compound (II) was easily converted into the pseudo-cyanide, m.p. 238–39° (decomp.), and this could be reconverted into the original hydrochloride. The authentic sample of dihydrosanguinarine also behaved in the same way with ferric chloride.

Further confirmation came from the oxidation of compound (II) to oxysanguinarine, isolation of a zinc-dust distillation product, m.p. 135–135·5°, giving the fluorescence test of Graebe[9] and agreeing with the formula of α-naphthaphenanthridine, and also from the transformation of (I) into 3.4.6.7-tetramethoxy-11.12-dihydro-N-methyl-α-naphthaphenanthridine, m.p. 183–85°, and giving a mixed melting point, 182–84°, with an authentic sample, m.p. 181–83°.

Sanguinarine has been isolated from argemone oil by chromatographic analysis of the oil on a silica column, and also from the crude precipitate obtained by passing dry hydrogen chloride into an ethereal solution of the oil; the amount of sanguinarine hydrochloride obtained by the latter procedure is 0·44 mgm./c.c. of oil. In this sample of oil, dihydrosanguinarine accounted for about 87 per cent and sanguinarine for about 5 per cent of the total alkaloids present.

When sanguinarine hydrochloride was injected intraperitoneally to albino rats in a dose of 2 mgm./100 gm. body-weight, there was 100 per cent mortality. In contrast to this, dihydrosanguinarine at about two and a half times this dose, or oxysanguinarine at about four times this dose, did not kill any of the rats injected. Sanguinarine hydrochloride was also toxic when fed by mouth, and by following a suitable procedure, young albino rats (40–96 gm.) could be killed usually within a week by administering 1 mgm. of the poison daily.

In further studies of the toxic effects of sanguinarine, the eyes of two albino rats about to die from a lethal intraperitoneal dose of the hydrochloride were removed by Dr. Pirie and Dr. Jackson, and sectioned. The sections, compared with those from normal eyes, showed that there was great congestion of the capillaries of the iris, choroid and retina.

Sanguinarine hydrochloride is toxic to some enzyme systems also. It has been found, for example, that it can inhibit the oxidation of pyruvate, lactate and succinate by pigeon brain preparations. In fact, the effect on pyruvate oxidation was very marked, and with the pigeon brain homogenates used in this laboratory, about 30–35 per cent inhibition of the total oxygen uptake in presence of added pyruvate was noticed with 0·041 m*M* concentration of the poison. Addition of cocarboxylase could not prevent this inhibition.

The observed inhibition of pyruvate oxidation strongly suggests the possibility that there should be accumulation of pyruvate in the blood of persons suffering from dropsy due to argemone oil poisoning. This agrees very well with an observation of Wilson and Ghosh[10] that there was a significant rise in the bisulphite-binding capacity of the blood in epidemic dropsy cases. In a preliminary experiment carried out here, a definite rise in blood pyruvate has been noticed in rats after a heavy dose of sanguinarine hydrochloride intraperitoneally.

The inhibitory effect of sanguinarine hydrochloride on some —SH enzymes suggested the possibility that it was probably combining in some way with the essential —SH groups. This was confirmed by the observation that when B.A.L. or monothioethylene glycol was treated with an excess of sanguinarine hydrochloride at *p*H 7·4, there was a precipitate containing sulphur and the filtered solution gave negative nitroprusside test. It has not been possible as yet to purify these compounds; but analysis of a nearly pure compound with monothioethylene glycol confirms the presence of sulphur in the compound and indicates also that very probably one molecule of the base is combining with one molecule of thiol.

In vitro experiments with the pigeon brain homogenates showed that if mixed before, 50 μgm. of B.A.L. could completely protect the pyruvate oxidase system from the toxic effect of 100 μgm. of sanguinarine hydrochloride—even 20 μgm. of B.A.L. could afford about 70 per cent protection. However, B.A.L. could not reactivate the already poisoned enzyme.

These results were confirmed by *in vivo* experiments. When albino rats were injected with an excess of B.A.L. (intramuscularly) 15–20 minutes before the administration of a lethal dose of the poison (2 mgm./100 gm., intraperitoneally), there was almost complete protection and about 85 per cent of the treated rats survived.

Since B.A.L. will not reverse the *in vitro* damage to enzymes, it is unlikely to reverse any toxic effects already established by sanguinarine, but it might be useful in preventing further damage due to any unreacted poison.

The poisonous nature of sanguinarine was known before and its pharmacological effects were studied by Meyer[11].

A detailed account of the work will be published at an early date.

My grateful thanks are due to Prof. R. A. Peters for his continued interest and help and for the facilities provided. I am indebted to Dr. A. Pirie and Dr. C. R. S. Jackson for examining the eyes of some of the experimental rats, to Prof. L. Ebert for samples of dihydrosanguinarine, sanguinarine nitrate and the tetramethoxy compound, to Dr. L. A. Stocken for the sample of B.A.L. and to Prof. S. N. Bose for the argemone oil. My thanks are also due to the Government of India for a research grant, and to the Carnegie Grants Committee of the University of Oxford for some financial help.

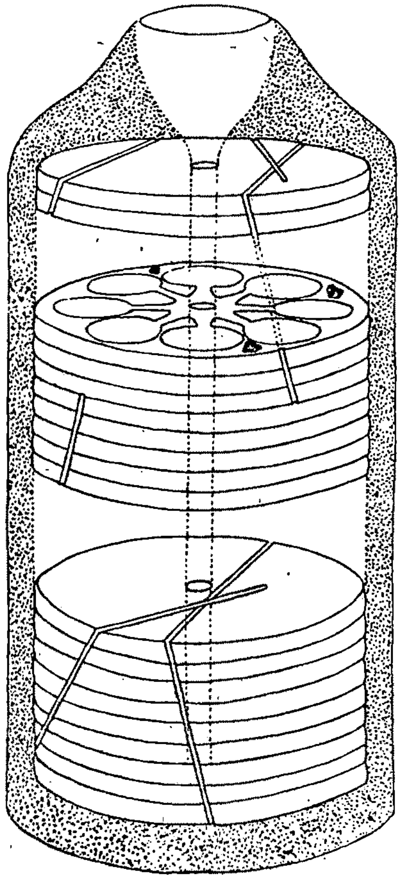
THE TECHNIQUE OF CASTING COINS IN ANCIENT INDIA

THE chance discovery by Prof. Birbal Sahni at Rohtak, some forty miles west-north-west of Delhi, in 1936, of a clay mould for the casting of a coin, later led to the discovery of many thousands of fragments of similar moulds. The bronze coin, about 19 mm. in diameter, of the Yaudheya series, has been dated about 100 B.C. From the very large amount of material available, Prof. Sahni has been able to work out in the greatest detail the entire story of the casting technique employed[1].

The accompanying figure illustrates the manner in which the mould was constructed. A pouring basin at the top leads to a central vertical runner, 7 mm. in diameter, from which, at successive levels, eight radial runners communicate with moulds for the same number of coins. The disks containing these moulds were 87 mm. in diameter and were built up into a pile, perhaps a foot or so in height. Around this there was a jacket of clay admixed with fragments of unhusked grain. When the mould was complete it was heated up to a surface temperature of the order of 600°–650° C., as a result of which the organic material was charred, leaving the jacket in a porous condition through which the gases could escape.

There can be little doubt that the moulding technique was carried out in the following manner. Around a wooden baseboard of the same diameter as the disks, and with a central peg 7 mm. thick fixed in the centre, a cylindrical container was placed, and a slab of plastic clay, sufficient for one disk, introduced. On this the side runners were first moulded from an 8-spoked metal pattern about 1½ mm. thick. At the ends of the spokes the coin moulds were pressed into the clay, a very large number of such patterns being employed, and any obstruction between the individual runners and the mould being removed. This disk was then dusted with a parting powder, such, for example, as wood-ash, and a second one prepared on top. In order to ensure exact register of the two surfaces of the disks, small irregular fragments of stone or brick were introduced into the lower disk while still plastic, producing a corresponding depression in the overlying surface. In this way a set of up to a dozen disks was produced, the upper and lower surfaces of each complete set being blank. On the removal of the surrounding cylinder, an oblique groove was marked across the upper surface of the disks and obliquely down the side. In most cases two such grooves are marked and the re-assembly of the disks (after drying) in their correct order thus facilitated. After air drying, the disks were re-assembled and a series of sets piled one on another to produce a mould of appropriate size.

This, after being covered with the jacket, was baked in some sort of furnace and the casting carried out while the mould was still hot, probably while still in the fire, with the pouring basin alone exposed.



When cold the mould was broken open and the coins broken away from the runners. The author suggests that on one of the two opposing faces an obstruction was often deliberately left between the side runner and the coin mould, providing a small notch which enabled the coin the more easily to be detached.

The question as to whether this coin foundry was legitimate or not is discussed by the author, who concludes—possibly on somewhat scanty evidence—that these moulds were not, in fact, the product of a forger. Whether this be so or not is quite immaterial, however, from the point of view of the most interesting information provided regarding a technique employed at this very early date. A comparison is also made with other conjectured reconstructions of Indian and other coin moulds of different dates and localities. In the latter cases, however, more material is needed to settle the details of the process with the same certainty which has been possible in the case of the Rohtak procedure. To the metallurgist and numismatist alike, this contribution is one of outstanding interest.

F. C. THOMPSON

ATOMIC ENERGY EXHIBITION: THE ATOM TRAIN

AFTER a tour lasting six and a half months, during which the Atomic Energy Exhibition, organised by the Atomic Scientists' Association, visited twenty-five of the main centres in England, Scotland and Wales, the exhibition came to a close on May 28. Efforts to secure an extension in Great Britain failed; but the exhibition will continue its existence abroad. The Council of the Atomic Scientists' Association, as well as the Ministry of Supply and other owners of equipment, have agreed to lend the exhibits to the United Nations Educational, Scientific and Cultural Organisation and the Lebanese Government for incorporation in an exhibition at the Unesco Conference in Beirut in October. Later it will probably tour several countries in the Middle East and, possibly, various European countries. Although the administration of the tour is left to Unesco, the Atomic Scientists' Association will be closely connected with it, and the atomic energy part of the exhibition will be known as that of the British Atomic Scientists' Association.

In Great Britain the exhibition was an outstanding success and excelled all hopes. It was visited by more than 146,000 people, making an average daily attendance of 1,000, which is 80 per cent of the maximum capacity. In many places people were queueing up for several hours. 85 per cent of the visitors came especially to see the exhibition, many of them making long trips for this purpose.

The reaction of the public was learnt from the answers of more than 1,100 people to a questionnaire handed out to a random sample of visitors. They show that the visitors represented a fair cross-section of the British public as regards occupations, with a slight bias in favour of the intellectual classes. 95 per cent of the public thought it worth while coming, and 91 per cent said that they had learnt something from the exhibition. The most interesting parts were found to be the counters and models (32 per cent) and the peaceful uses (24 per cent); the atom bomb section was the main item of interest for only 7 per cent. Quite a large number of people expressed surprise that atomic energy could be used for constructive purposes as well. The main criticism of the exhibition was that it was not big enough and too crowded.

The guide book to the exhibition sold extremely well. Altogether more than 50,000 copies were sold or presented, making it the most popular and widespread publication on atomic energy.

The performance of the technical equipment, most of which was very delicate and tricky to operate, was extremely satisfying. Some of the experiments were demonstrated publicly for the first time and only a few years ago could not have been made to work reliably even with the best care in the laboratory. Here they were subjected to the most adverse conditions, to the movement of the train on a 1,900-mile journey, to differences of temperature ranging from 30° to 100° F., to a wide range of voltages in the various places and, above all, to the heavy hands of about 130,000 adults and 16,000 inquisitive children.

Not only has the equipment withstood the test magnificently, but also it has beaten all records for endurance of this type of apparatus. The scaling units are supposed to have a life-time of 200 hours, and yet during the 1,600 hours of operation of five scaling units, only one valve had to be replaced. Throughout the whole tour, each Geiger counter had to be replaced only once. The total time when the exhibits were out of commission amounted to less than 1 per cent and the total expenditure on maintenance of equipment, including replacement of films, fluorescent tubes, etc., was less than £50.

All this is evidence of the good quality and high-class workmanship of the British firms who manufactured it; it is also a tribute to the technical staff who looked so well after the maintenance of the equipment.

The Atomic Energy Weeks, which were organised in conjunction with the exhibition, were also very successful and the lectures and film shows were well attended.

Summing up, it can be concluded that the exhibition achieved its main object—that of educating an appreciable fraction of the British public in matters of atomic energy.

ROTHAMSTED EXPERIMENTAL STATION

REPORT FOR 1946

THE return to peace-time activities at Rothamsted Experimental Station enabled much of the fundamental and long-range work to be resumed, and the report for 1946 now issued includes a short account of such investigations, as well as of new work undertaken by the various departments. There are departments of physics, chemistry, soil microbiology, botany, crop physiology, statistics, plant pathology, biochemistry, entomology, insecticides and fungicides, and one for the study of bees. This list of departments indicates the very wide scope of the work at Rothamsted, and it is impossible not to be impressed by the advantages that must accrue from the ready contacts that are possible between the workers in the various sections. The experimental farm, together with that of Woburn, one on heavy and the other on light soil, offers every facility to the research worker, and the work of the Statistical Department enables field-work to be carried out with the maximum of effect. Field-work is not confined to the two farms, many careful experiments being carried out at various centres in the country; thus the main set of tests on the manuring of sugar beet, for example, involves some twenty commercial farms annually.

In a note of this length, it would be impossible to do justice to the work of so many departments; a reviewer can but mention one or two out of many significant lines of work. The experiments on deep ploughing and on cultivations have interested scientific men and farmers for some years, and the resumption of this work is welcomed. Results available before the War indicated that much time and money are lost on the farms of Britain in excessive cultivations; but farmers and Rothamsted workers alike felt that such unexpected results needed more corroboration. It has generally been considered that, in so far as yield of crop is concerned, the more and the deeper the cultivation the better; we used to point out the large, if expensive, crops raised in some gardens, where trenching is carried out, etc., and where no expense is spared on the preparation of the seed bed. The work at Rothamsted, however, which included experiments at many centres in 1944 and 1945, did not indicate any advantage from deep ploughing or from sub-soiling for potatoes or beet, and very little for wheat. Observations of root development and of the physical properties of the soil showed that none of the properties was influenced by deep cultivation.

The theoretical and experimental work on the movement of water in soils, and on evaporation, is also of great interest. Most of us have had the experience of observing small patches of a crop that have made far better growth than that of the surrounding plants, due to some physical character of those portions of the seed bed; for example, consolidation as the result of pressure from a tractor wheel, or greater pulverization on a headland where some implement may have been turned round, and where upward movement of water in the soil was presumably facilitated. On other occasions, under different weather conditions, these excessively consolidated or pulverized areas have carried the poorest plants. It is not easy for even the most experienced farmer to achieve the optimum seed-bed condition every season, and there will always be an element of chance about this until more fundamental knowledge is available about the physical properties of the soil, particularly in regard to water.

The Department of Chemistry commenced work in 1945 on forest nurseries, and interesting results are already available. It is interesting to note, for example, how the growth of Sitka spruce was improved by acidifying a slightly calcareous soil on which this species had consistently failed for a number of years. Work already carried out is sufficient to indicate that fruitful lines of research lie ahead in this field.

Work carried out in the Department of Soil Microbiology on the micro-organisms capable of the selective destruction of soil bacteria may be noted as of particular interest. The maintenance of satisfactory biochemical activity in a field soil depends on several factors, not the least important of which is the existence of micro-organisms that limit the numbers of useful organisms, either by competing with them for nutrients, or by producing toxic secretions, or by directly eating them. A number of strains of bacteria were subjected to attacks by five predatory organisms, and by three species that are destructive to bacteria by virtue of their secretions. It was found that any one species of organism could attack about half the bacterial species tested; the organisms, however, differed markedly as to which particular bacterial strain they attacked. It seems likely that very few species of bacteria exist in the soil that are immune to attack by some of the micro-organisms.

Current advances in the use of insecticides lend great interest to the Rothamsted investigations in that field. Experiments are in progress on various aspects of the use of D.D.T. and of benzene hexachloride, including the effect of these on bees.

Tables giving the detailed results of the experimental work have been omitted, since it is intended to issue these separately. The report includes a list of the scientific papers from each department, with a short note on the contents of each, and also a list of the publications of the Rothamsted Experimental Station.

PACIFIC SCIENCE BOARD

FIRST ANNUAL REPORT

THE first annual report of the Pacific Science Board (National Research Council, Washington 25), set up as a result of the Pacific Science Conference 1946, covers the year 1947, and outlines the steps being taken under the project for the co-ordinated investigation of Micronesian anthropology to fill gaps in our scientific knowledge of the Marshall, Caroline and Mariana Islands, and to provide the basic information required in setting up civilian government in these trust territories of the United States. A permanent Insect Control Committee has been appointed for Micronesia, and five entomologists have been sent to survey the distribution and destruction of coco-nut palms caused by the rhinoceros beetle (*Oryctes rhinoceros*), to study the coco-nut beetle (*Brontispa mariana*) and the giant African snail (*Achatina fulica*) and to search for parasites or natural enemies for the control of these pests. An entomological survey of the Palau Islands is also in progress.

Approval was given for eight other field projects and in general the Board's policy is to give stronger endorsement and higher priority to proposals for intensive and long-range research than to those for extensive but superficial surveys or short-term projects. In accordance with the desire to strengthen Honolulu as a centre for research in the Pacific, the Board generally recommends that reference collections from the area should be deposited with appropriate institutions in Honolulu.

The Pacific oceanic biology project is now actively engaged in studying, analysing and evaluating the data already available, with headquarters at the Woods Hole Oceanographic Institution; and plans are now being developed for establishing a new Hawaii Marine Laboratory on an island in Kaneohe Bay, Oahu. The Board also hopes to co-operate with the research council to be set up by the South Pacific Commission in developing plans for research in that area, and conservation planning in the Pacific should be greatly assisted by three forthcoming international conferences: the meeting of the Standing Committee for the Protection of Nature in and around the Pacific, at the Seventh Pacific Science Congress to be held in New Zealand in February 1949; the Economic and Social Council of the United Nations Scientific Conference on the Conservation and Utilization of Resources, to be held in the United States in May 1949; and the United Nations Educational, Scientific and Cultural Organisation's Conference on the Protection of Nature also to be held in the United States in May 1949.

Future activities contemplated include the encouragement of oceanographic and fisheries research in various parts of the Pacific, the initiation of a conservation programme for Micronesia, and the initiation of field studies in the Pacific area to further research bearing on problems in cancer and heart disease.

CARNEGIE UNITED KINGDOM TRUST

THE thirty-fourth annual report of the Carnegie United Kingdom Trust for the year 1947 emphasizes the increasing rate of expenditure, which rose from £120,000 in 1946 to £160,000 in 1947, thus exceeding the annual expendable income of about £133,000. The quinquennial policy for 1946–50 was framed on the assumption, however, that during the period a substantial part of the accumulated savings of the war years would be applied as annual revenue, and the Trustees are more concerned at a second feature of the period—the increasing proportion of expenditure allocated to the provision of services rather than buildings or capital assets.

The largest bulk allocations, totalling £150,000 each, for the Bureau of Current Affairs and for the development of amateur music and art, are wholly concerned with services, and this is also true of the £25,000 allocated to enable local organisers to be appointed by County Federations of Young Farmers' Clubs. Although the 'village hall' allocation of £100,000 is designed to help capital expenditure, payments have amounted to less than £7,500 in two years. Past experience of the Trustees indicates that grants for capital purposes have been more certain in their operation than grants for the early maintenance of services, and accordingly they regret the present restricted opportunities in the capital field. In view of the unsatisfactory position of the village halls scheme, it has been decided that when the Trust allocation of £100,000 has been exhausted by promises, subsequent schemes shall be eligible for consideration for Exchequer grants under the Physical Training and Recreation Act. For the village planning competition, forty-seven entries were received and the winning design is regarded by the adjudicators as quite outstanding. The Trust has also agreed to find up to £400 a year for a two-year programme of pioneer work for young women from the Channel Islands, partly by visits of expert organisers from England and partly by courses of instruction in England.

The report refers to the passing of the Irish Central Library for Students under an independent governing body, the Library Council established by the Public Libraries Act of 1947 (Eire). Grants to three county libraries in Eire have also been agreed in principle, and the committee set up to consider the future of the Scottish Central Library reported unanimously in September 1947 that the Library should not be merged with the National Central Library, although continuing to work in the closest co-operation and consultation with that Library. Some form of constitutional link between the two Libraries was recommended; but it was considered that the time was now ripe for establishing the Scottish Central Library on an independent basis, with its own trustees and governing body and an initial income of £5,000, in new premises in Edinburgh. The grant to the National Central Library has been progressively decreased to £3,000, £2,000 and £1,000 for the three ensuing years and will become extinct on December 31, 1950.

Sufficient progress has been made with the Shropshire Community House at Attingham Hall, near Shrewsbury, to justify the appointment of a warden, and the Highlands and Islands Film Guild has made a very satisfactory start and is now working on a programme of six mobile film units.

STANDARD FREQUENCY TRANSMISSIONS IN GREAT BRITAIN

THE question of radiating standard frequency transmissions from Great Britain has recently been under consideration. Such transmissions are of great value in connexion with the calibration of industrial and scientific frequency sub-standards, in connexion with work on radio wave propagation and also for survey purposes. At present, standard frequency transmissions of guaranteed accuracy are emitted by the U.S. National Bureau of Standards[1] continuously on the eight frequencies 2·5, 5, 10, 15, 20, 25, 30 and 35 Mc./s. from station WWV. Unfortunately, on account of radio propagation conditions, it is often difficult to make good use of the American transmissions in Europe and farther east. At the recent meeting of the International Telecommunications Union at Atlantic City, it was agreed that the first six of the above frequencies (namely, 2·5, 5, 10, 15, 20 and 25 Mc./s.) should be allocated on a world-wide basis for all future standard frequency transmissions. Hence, if undesirable interference between such transmissions is to be avoided, all new services of standard frequency transmissions will require very careful co-ordination with existing services.

In Great Britain, an experimental low-power transmission from station GMT, on a frequency of 2 Mc./s., has been set up by the Royal Observatory at Abinger, Surrey, to facilitate comparisons between quartz clocks used in the operation of the Greenwich time service. Details of this service have been published recently[2]. Since no other British standard frequency service is at present available, these transmissions have been fairly widely used, and a substantial increase in power is under consideration.

In existing circumstances the provision in Britain of a comprehensive service on a number of the available frequencies will take some considerable time; but arrangements are now under consideration whereby a limited standard frequency service on three frequencies will be operated by the General Post Office. It is hoped that experiments connected with the new service will demonstrate the feasibility and value of covering the United Kingdom and Europe in this way, and also the degree of interference from and with the WWV transmissions.

Details of this experimental service will be announced later; but meanwhile it may be mentioned that the frequencies of the following transmitters of the General Post Office and of the B.B.C. are maintained at their nominal values to a tolerance better than ± 1 part in 10^6.

Station's call sign	Nature of service	Location	Nominal frequency kc./s.
GBR	Telegraph	Rugby	16
—	Broadcast	Droitwich	200
GRO	Broadcast	Skelton	6,180
GSB	Broadcast	Daventry	9,510
GSV	Broadcast	Daventry	17,810

The B.B.C. medium-wave transmitters, with the exception of that on 583 kc./s. (514 m.), are also maintained on their nominal frequencies to a tolerance of approximately ± 1 part in 10^6.

ELECTRIC CONDUCTIVITY OF ROCKS AT HIGH TEMPERATURES

H. P. COSTER has described the results of measurements of the electric conductivities of various rocks (*Mon. Not. Roy. Astro. Soc.*, Geophys. Supp., **5**, No. 6, January 1948). The conductivity was determined on specimens of rock cut in the shape of a cylinder, by measuring the resistance between the electrodes in a D.C. bridge circuit; the current in the bridge was reversed after balancing, with the object of detecting potentials due to polarization of the rock by electrolysis. Although a small effect was usually found, its influence on the resistance was never more than a few per cent. The conductivities determined for different rocks showed that they could be classified as semi-conductors, and in many semi-conductors the relation between the conductivity and the absolute temperature T is given by

$$\sigma = A_1 \exp(-\varepsilon_1/kT) + A_2 \exp(-\varepsilon_2/kT) + \ldots,$$

where k is Boltzmann's constant, $\varepsilon_1, \varepsilon_2$, etc., are the activation energies of the various processes to which the conductivity is due, and A_1, A_2, etc., are constants.

The results of the experiments are shown graphically, $\log_{10} \sigma$ being plotted against $10^3/T$, for eight different rocks—all Scottish—which Prof. C. E. Tilley placed at the disposal of the author. The curves show that the conductivity of most of the rocks is due to at least two mechanisms: one with an activation energy of about 0·7 volt and the other with an activation energy of the order of 2 volts, the latter appearing at higher temperatures; experiments on the nature of the conductivity suggest that in this case it is caused by moving ions.

The theoretical implications of the results with regard to the conductivity in the interior of the earth are discussed, and the following suggestions are made. At a depth of a few kilometres where the rocks are probably dry, the conductivity is lower than it is nearer the surface; but as greater depths are reached, where the temperature is higher, the conductivity should start to increase. Assuming that pressure has no effect on the conductivity, a value of 0·01 ohm^{-1} cm.$^{-1}$ should be reached at a temperature of 1,200–1,400° C., possibly at a depth of 160 km. The effect of pressure is, however, a serious source of uncertainty in the investigation; but using the temperatures and pressures given by Bullard and Bullen, respectively, Coster has compiled a table which shows the variation of temperature, pressure and conductivity with depth, though the relation cannot be regarded as anything more than an approximation. At depths greater than 200 km. the increase in conductivity is rather small, because the effect of increase in temperature is almost compensated by that of increase in pressure. The figures, though giving only a rough idea of the variation of conductivity with depth, nevertheless can account for the increase of conductivity with depth found by Chapman and Price.

MEXICAN VILLAGE LIFE

THE monograph under notice*, the sixth of a series dealing with the sociology of Latin America, returns to the Mexican Highlands and to the Tarascan pueblo of Tzintzunzan. This village, which at the time of the Spanish conquest was the capital of an empire second only to the Aztec in size, has now become a sleepy Mestizo community of 1,500 souls which is "probably typical of a vast number of small rural Mexican pueblos". "Empire's Children" is a very readable account of this engaging and happy-go-lucky community of potters and farmers where "the great majority of the villagers get down to work only with a tremendous exertion of will power and stop on the slightest pretext", and where "Russia, Communism, the United States and Protestantism are conveniently lumped together as enemies of the inalienable rights of man".

The author's purpose is to convey a general and comprehensive impression of the social and economic life of these people, and he has been more than usually successful in achieving this. The reader is neither overwhelmed with masses of unnecessary detail nor mystified by technical anthropological jargon, and yet practically every aspect of village life is covered—its history and prehistory, its domestic and its material culture, its trade and commerce and its social, political and religious institutions. His summing up and conclusions are not so impressive, probably because of his short acquaintance with the country (two years) and possibly because although he admits the essential unity of the Mestizo culture, he remains too preoccupied in distinguishing the Spanish and Tarascan traits which contribute to its 'total configuration'. However, this summary only takes up eight pages at the end of the monograph and is probably inserted for the benefit of the Mexican Government rather than for the general reader.

It is to be hoped that this preliminary survey will be succeeded by detailed studies of the more striking aspects of rural Mexican society, in particular, of the part played by the Church, a role so vital that Foster considers it the "socio-spiritual focal point of the culture".

SOIL IMPROVEMENT FOR FORESTRY

THE Reports of the Forest Research Institute of Sweden, Vol. 36 (Centraltryckeriet, Esselte AB, tockholm, 1948) contains papers of considerable terest. Omitting those dealing with volume and ther measurements made in different parts of the ountry, sample plots and yield tables, and papers n forest pests, an article of importance to other untries is that of Carl Olof Tamm entitled "Soil-mproving Measures Tried on a Poor Site". The ork is described as a final report on work started n 1922 by the Swedish Institute of Forest Research n co-operation with the Forest Protection Board of he district of Jönköping, following an initiative aken by W. Lothigius, who was at that time the oard's executive forest officer. The aim of the work as been to try some possibilities of raising the poor orest yield frequently found on sandy soils within the istrict and elsewhere in the province of Smaland. arlier reports have been published by O. Tamm, ho planned the experiments and was responsible for llecting data on the plots as long as he remained ith the Institute (up to 1938).

The plots are at lat. 57° 34′ N., long. 22° 12′ E. hey occupy an area known as the Mölna Field on a and flat that was formerly mostly covered by old orest. In the experimental field, the forest was felled uring 1918–19.

After describing the area and its previous vegetative overing, the methods of re-afforestation are treated y means of a number of experimental plots. Nine trips were laid out, numbered III–XI, each 50 mm. ide. Furthermore, the main experiment is divided n ten rows, crossing the strips at right angles. Row No. 7 is 37·5 m. wide, Row No. 8 is 62·5 m.; all other ows are 25 m. wide.

Strips Nos. III and V were sown in 1923 with pine ixed with spruce. In strip No. III the mor cover round each seedspot was loosened and mixed with he sand: no positive effect of this treatment was ver observed. At the same time, strip No. IV was lanted with birch (about 1,000 per hectare, side-hole lanting) and then sown with pine mixed with spruce. trip No. VI was planted with *Alnus incana* instead f birch, and sown with pine.

Strip No. VII and the following strips were planted n 1922, the former with pine 1/0 and spruce 2/0 ratio 2 : 1), No. VIII with birch as No. IV and pine nd spruce, No. IX with pine and spruce, No. X with *Alnus incana* as No. VI and pine, and No. XI with pine only. The conifer seedlings were planted y the slit method.

The number of seedspots per hectare was intended o be 6,000 all over the field, but this figure is rather pproximate. All pine and spruce seed used came rom the same province; but the birch and *Alnus ncana* seedlings originated from Bastad (Skåne).

In Strip No. VII each planting hole was manured with peat from a birch carr; seven or eight litres of eat were mixed with the earth in each hole before lanting. The other treatments were done in different ows. The rows Nos. 1, 3, 5 and 7 were controls no treatment). Within rows Nos. 2 and 6 the soil was ripped by a kind of harrow. Within row No. 4 bout 400 gm. lime (calcium carbonate was used rom the sulphate mill at Gotafors) was mixed in each ole. Within rows Nos. 8 and 10 tree-debris from the lear felling were removed and taken to row No. 9.

Most of the pines, planted or sown, grew well in the first few following years. The planted spruces grew well, too; but the spruce seed used had a poor capacity of germination. The birches and alder seedlings generally did not stand the hard conditions at Molna Field, especially the frosty climate. Within small areas seedlings of all kinds suffered, either from fungus injuries or from starvation. Attempts were made to fill blanks by repair plantings in 1926 and 1930.

Two diagrams give results from observations in 1932. The brush-manured row (No. 9) had a small number of seedlings but a high percentage of good pine. Many seedlings were spoiled by capercailzies that found shelter in the brush cover. The peat strip (No. VII) showed a slight excess over the others, both in number of seedlings and in percentage of good pine. None of these deviations is significant.

The paper should be consulted for full details. In summing up, the author writes: "The Mölna experiment has been helpful in drawing attention to some factors determining forest yield on poor sandy soils. Yet, in order to have a more definite idea of the parts played by humus conditions, on one hand, and by geology on the other, fresh data must be obtained on plots where the conditions at the start of the experiments are carefully determined. The problems at issue have proved much more complicated than was realized in 1920."

SOME FUNGI OF INDIA

SIX new species of fungi occurring in Mysore have been described by M. J. Thirmulachar (*Trans. Brit. Mycol. Soc.*, 31, 1; July 1947). *Sphaceloma santali* attacks the leaves of the sandal tree; *S. osyridis* parasitizes leaves of *Osyris Wightiana*; *S. oleanderi* produces an anthracnose on oleander, and *S. curcumæ* causes leaf-spot of wild turmerics. *Cladochytrium aneuræ* is an interesting species weakly parasitic within the thallus of a liverwort (*Aneura* sp.), and *Leptosphæria porellæ* causes wilting of the bryophyte *Porella*. Mycological descriptions of the new species are given. Two further new species of *Physalospora* attacking *Pterolobium indicum* and *Heterostemma tanjorense*, two species of *Septoria* parasitizing *Erythrina* sp. and *Thespesia populnea*, with *Cereospora adinæ* on its name host, are fully described by T. S. and K. Ramakrishnan (*Proc. Ind. Acad. Sci.*, B, 26, No. 1, 7; July 1947).

Several papers have also been published on *Phytophthora palmivora*, which causes a fruit rot of tomatoes and a seedling blight of *Hibiscus esculentus*. T. S. Ramakrishnan and C. K. Soumini have studied the fungus on tomatoes (*Proc. Ind. Acad. Sci.*, B, 25, No. 2, 39; Feb. 1947). They isolated the fungus, proved its pathogenicity, found it could enter unwounded fruits, and, as infection appears most readily on fruits in contact with the soil, suggested proper support of tomato plants as a simple means of prevention. M. S. Balakrishnan (*Proc. Ind. Acad. Sci.*, B, 26, No. 4, 142; Oct. 1947) established the pathogenicity of *P. palmivora* on *Hibiscus* seedlings. A minus strain was isolated, and did not form oospores until paired with a plus strain of the same species. Further studies on this heterothallism have been made by K. M. Thomas, T. S. Ramakrishnan, C. K. Soumini and M. S. Balakrishnan (*Proc. Ind. Acad. Sci.*, B, 26, 147; Oct. 1947).

R. P. Asthana has investigated several characters of *Sclerotium cepivorum* and *S. tuliparum* (*Proc. Ind.

Acad. Sci., B, 26, No. 3, 93; Sept. 1947). *S. cepivorum* grows best on an acid medium, whereas *S. tuliparum* favours neutral or slightly alkaline conditions. Both species have an optimum temperature of 20° C. Neither species is able to attack the host of the other; but *S. tuliparum* can infect several bulbous plants in addition to the tulip. Both species secrete pectinase, though there is evidence that each host type is more sensitive to the enzyme of its specific parasite than to that from the other.

A threefold chain of parasitism is described by S. Y. Padmanabhan (*Proc. Ind. Acad. Sci.*, B, 26, No. 3, 77; Sept. 1947), who found a species of *Fusarium* attacking pupæ of *Epipyrops*, which in the larval stage is a parasite of *Pyrilla*, a pest of sugar-cane. The fungus is variable in culture, but is regarded as *F. moniliforme* var. *subglutinans*. Six new hosts of the ergot fungus *Claviceps* are given by T. S. Ramakrishnan (*Proc. Ind. Acad. Sci.*, B, 26, No. 4, 136; Oct. 1947), who also describes the fungus upon each. Miss H. Sunanda Kamath investigated the life-history of *Puccinia ruelliæ* on *Ruellia prostrata*, a common perennial weed in south India. It was found to be a macro-cyclic, autœcious rust, and the sequence of development of all the spore forms was followed by inoculation experiments.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER IN BOTANY—The Registrar, The University, Nottingham (August 21).

DAVID BROWN SCHOLARSHIP IN AGRICULTURAL ENGINEERING—The Registrar, King's College, Newcastle-upon-Tyne (August 21).

PAINT AND VEGETABLE OIL CHEMIST (graduate) to take charge of research and to teach a small post-graduate class, and a GRADUATE TECHNOLOGIST to teach vegetable oil extracting and paint manufacturing processes, at the Instituto de Oleos, Rio de Janeiro—The Director, Personnel Department, British Council, 3 Hanover Street, London, W.1 (August 21).

PHYSIOLOGIST (male) with an Honours degree in Science, and a BACTERIOLOGIST with Honours degree, or an Honours Graduate in Science with experience in Bacteriology—The Secretary, Hannah Dairy Research Institute, Kirkhill, Ayr (August 21).

LECTURER (man or woman) IN AGRICULTURAL SCIENCES at the Cheshire School of Agriculture, Reaseheath—The Director of Education, County Education Offices, City Road, Chester (August 21).

FORD MOTOR COMPANY SCHOLARSHIPS IN AGRICULTURAL ENGINEERING—The Registrar, King's College, Newcastle-upon-Tyne (August 21).

LECTURER (Grade III) IN THE DEPARTMENT OF GEOGRAPHY (with special qualifications in Meteorology and/or Geomorphology)—The Clerk, Birkbeck College, Breams Buildings, London, E.C.4 (August 21).

DEMONSTRATOR OF PHYSICS—The Dean, Medical School, Guy's Hospital, London, S.E.1 (August 23).

SCIENTIFIC OFFICER (Zoologist, for work especially on plankton) at the Millport Laboratory—The Secretary, Scottish Marine Biological Association, 185 St. Vincent Street, Glasgow, C.2 (August 24).

LECTURER or ASSISTANT LECTURER IN STRUCTURAL ENGINEERING—The Registrar, College of Technology, Manchester 1 (August 30).

ASSISTANT IN ZOOLOGY FOR RESEARCH IN ENTOMOLOGY, with minor teaching duties—The Secretary of University Court, The University, Glasgow (August 31).

AGRICULTURIST IN THE SOUTHERN RHODESIA GOVERNMENT SERVICE—The Office of the High Commissioner for Southern Rhodesia, 429 Strand, London, W.C.2 (August 31).

LECTURER IN CHEMISTRY with special qualification in physical chemistry—The Secretary, The University, Old College, South Bridge, Edinburgh (September 1).

LECTURERS IN MATHEMATICS, and LECTURERS IN SCIENCE (physics, mechanical or electrical engineering, or chemistry), at the Royal Military Academy, Sandhurst—The Secretary, Civil Service Commission, Burlington Gardens, London, W.1, quoting No. 2254 (September 4).

LECTURER IN SOCIAL SCIENCE and Supervisor of Studies for the Diploma Course in Social Science—The Registrar, University College, Singleton Park, Swansea (September 11).

CARGILL CHAIR OF NATURAL PHILOSOPHY, tenable in the subject of Theoretical Physics—The Secretary of University Court, The University, Glasgow (September 11).

ASSISTANT INSPECTORS OF MINES AND QUARRIES under the Ministry of Fuel and Power—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2246 (September 11).

DIRECTOR OF MUSEUMS to take charge of the Museum Section of the Art Galleries and Museums Department—The Town Clerk, City Chambers, Glasgow, C.2 (September 15).

CHAIR OF APPLIED MATHEMATICS—The Registrar, University Colleg Southampton (September 20).

LECTURER IN GEOLOGY, within the Department of Agricultur Chemistry, and an ASSISTANT LECTURER IN PLANT DISEASES in th Department of Agricultural Botany—The Secretary and Registrar University College of North Wales, Bangor (September 25).

SMITHSON RESEARCH FELLOWSHIP—The Assistant Secretary, Roya Society, Burlington House, Piccadilly, London, W.1 (October 30).

TUCKER-PRICE SCIENTIFIC RESEARCH FELLOWSHIP in mathematic science or an allied subject—The Secretary, Girton College, Cambridg (January 15).

CHEMIST IN THE DEPARTMENT OF CHEMISTRY, Tanganyika—Th Director of Recruitment (Colonial Service), Colonial Office, 2 Sanctuar Buildings, Great Smith Street, London, S.W.1.

UNIVERSITY GRADUATES and QUALIFIED TEACHERS, with qualifications in mathematics, science, engineering, or in geography wit mathematics up to intermediate degree standard, for Short Servic Commissions in the Education Service, Royal Navy—The Director (P Education Department, Admiralty, London, S.W.1.

LECTURER IN MATHEMATICS to B.Sc. standard, a LECTURER I CHEMISTRY to B.Sc. standard, and a LECTURER IN PHYSICS to B.S (Special) standard—The Clerk, Northern Polytechnic, Holloway London, N.7.

TECHNICIAN FOR THE DEPARTMENT OF ZOOLOGY—The Clerk Birkbeck College, Breams Buildings, London, E.C.4.

LABORATORY TECHNICIAN (bacteriological technique essential) I THE PATHOLOGY DEPARTMENT—The Secretary, Welsh Nationa School of Medicine, 10 The Parade, Cardiff.

SOIL SURVEY OFFICER—The Secretary, Rothamsted Experiments Station, Harpenden, Herts.

RESEARCH METALLURGIST, and a SENIOR ASSISTANT IN THE INFORMATION DEPARTMENT—The Secretary, British Non-Ferrous Metal Research Association, 81–91 Euston Street, London, N.W.1.

ASSISTANT TECHNICIAN for university laboratory involving botanica and chemical work—Dr. J. W. Fairbairn, School of Pharmacy, 1 Bloomsbury Square, London, W.C.1.

SCIENTIFIC ASSISTANT with a knowledge of electronics for work i X-Ray crystallography—Dr. W. A. Wooster, Cavendish Laboratory Cambridge.

TECHNICAL OFFICER (with a degree or diploma in, and a soun practical knowledge of, horticulture)—The Curator, John Inne Horticultural Institution, 31 Mostyn Road, London, S.W.20.

VETERINARY RESEARCH OFFICERS (2) in the Sudan Veterinary Service, for supervising the preparation of various biological product and carrying out general research—The Sudan Agent in London Wellington House, Buckingham Gate, London, S.W.1, endorse 'Veterinary Research Officer'.

SCIENTIFIC OFFICER and EXPERIMENTAL OFFICER Grades in Ministry of Supply Research Establishments in the following fields of work Chemistry—Inorganic, Organic, Physical, Analytical, and Chemica Engineering (Ref.F.355/48A); Biochemistry, Physiology, Pharmacology (Ref.G.184/48A); Aerodynamics—subsonic and supersonic i wind tunnels and in flight (Ref.A.160/48A); Aircraft Structural Theor (Ref.C.301/48A); Gas Turbines, jet and rocket propulsion at supersonic speeds (Ref.C.299/48A); Physics, including optics, gas kineti and thermodynamics (Ref.A.159/48A); Radar (Ref.A.161/48A) Aircraft Instrumentation and electrical and radio accessories, etc (Ref.C.300/48A); Metallurgy, X-Ray diffraction, electron microscopy inter-crystalline corrosion, high temperature materials (Ref.F.356/48A) Mathematical Applications, including ballistics, statistics (Ref.A.158 48A)—The Technical and Scientific Register (K), York House, Kingsway, London, W.C.2.

THE ROCKEFELLER FOUNDATION

THE reviews of the work of the Rockefeller Foundation which we are accustomed to receive from its President are far more than mere summaries of the activities of the Foundation during the year under review. They represent an intellectual stock-taking—an assessment of the position of the creative forces of civilization, its moral and spiritual, as well as scientific, resources, and an attempt to appraise the directions in which special efforts are required. Dr. Fosdick's review of 1947 is no exception, and with insight and courage delineates the challenge which Western society faces to-day and the points at which special efforts are necessary to avert pressing danger.

Dr. Fosdick starts his review with a glance at the appropriations of the Foundation during 1947. Amounting to 23,413,615 dollars, or nearly four million dollars more than those in 1946, they represent the largest annual appropriation in the history of the Foundation. They include a single grant of ten million dollars to the China Medical Board for the support of the Peiping Union Medical College, another 2,225,000 dollars for public health, and 1,500,000 for medical sciences, 1,700,000 for natural science, 3,000,000 for social sciences and 1,500,000 dollars each for the humanities and for the General Education Board. Of this total 39 per cent was for work in the United States and 61 per cent for work in other countries.

The central issue to which Dr. Fosdick directs attention in this report is that of the misuse of knowledge, and while he recognizes that in the present situation an element of physical force is essential he insists that that alone will be of no avail unless we meet the challenge on an intellectual and ethical plane. Here the emphasis on the task of raising the material standards of living can be an obstacle. A solid material foundation may be an essential basis for a high civilization; but Dr. Fosdick points out that it is a basis and not a superstructure. So, too, our reverence for the physical sciences and acceptance of the doctrine that civilization can be bred to greatness and splendour by science hinders our responding to the challenge at a higher level. The gap between the physical sciences and the humanities and social studies, in terms of endowment, research facilities and teaching staffs, needs to be closed, whereas in fact it is growing wider.

Dr. Fosdick recognizes the debt which mankind owes to science in giving us the methods and patterns of research in human relationships; but he insists that to the problem of discovering a new set of human purposes, to the art of human relations, to the winning of wisdom, physics, chemistry and engineering contribute little. They are ethically neutral, and the issues of our time and of human destiny will be determined not at the physical but at the ethical and social levels. If this age is to achieve greatness it will not be through its physical triumphs, but through the discovery of an enlightened humanism and of new spiritual and moral values that lead men forward.

The immediate task, in Dr. Fosdick's view, is to discover the common interests, the areas in which collaboration is possible, where curiosity and sympathy, aspiration and mutual advantage overlap. The search for these rallying points, the development of new techniques and areas of co-operation where ideas and experience can be pooled and combined, lays the foundation of the ultimate structure of a unity never yet achieved in the world. In this connexion it should be noted that while representatives of the Rockefeller Foundation visited practically every country in the world in 1947, visas to enter Bulgaria and the Soviet Union could not be obtained and no contact could be established with their scholars and scientists. And in all the countries which representatives of the Foundation visited the passionate desire for peace, security and a better life formed the universal pattern of thinking and planning, whatever the differences of opinion as to the means by which these ends are to be achieved.

We have already noted in these columns Dr. Fosdick's comments on the unhappy effects of isolationism on science and the major responsibility which here rests on the Soviet Union. It is because medicine stands so clearly above political ideology that Dr. Fosdick justifies the large appropriation for the development of modern medicine in China at the present time, as he does the increasing support given in the field of public health. There also the widening horizons, the fading of the borderlines between curative and preventive medicine, are giving public health the stature of a social science in the service of society. Dr. Fosdick clearly looks upon the World Health Organisation of the United Nations as a real unifying force in the world and one vehicle through which our new knowledge and widening conceptions of public welfare may make health, if not infectious, at least within the reach of all men.

Another unifying factor, at least in the world of science, is what Dr. Fosdick describes as the cross-breeding of biology with physics as well as chemistry. Biophysics, in particular, with its demands for such expensive equipment as ultracentrifuges, X-ray equipment, spectrophotometers and cyclotrons, demands co-operation across national frontiers, and the Foundation made a number of large grants in this field in 1947, including 250,000 dollars to the Massachusetts Institute of Technology, 50,000 dollars to the California Institute of Technology, 85,000 dollars to Prof. W. T. Astbury at Leeds, and 21,000 dollars to Prof. J. T. Randall, director of the Biophysics Unit of King's College, London.

Of the grants in the field of social sciences and in the humanities, Dr. Fosdick observes that they are intended to assist a more adequate analysis and understanding of the issues in international relations, to widen the horizons of the political and economic life of men, to extend the frontiers of the mind in time as well as in space. The programme of research assisted from this point of view also has claims upon the interest of the physical as well as of the social scientist. One particular problem is of exceptional interest at the present moment and is a challenge to this country which is unmistakable.

During 1947 Dr. R. J. Havighurst, of the Universit of Chicago, made an extensive study for the Found tion of the situation in Germany as regards tl universities, primary and secondary schools, librarie youth problems and policies, teacher training, co tacts with the outside world and so on. Dr. Fosdic summarizes very briefly the observations and recon mendations of this report, stressing the poverty Germany and the utter isolation which affects mar men of goodwill in Germany, and asserting th nevertheless the foundations for a peaceful ar productive democratic society are present in Germar to-day. Moreover, the two prerequisites to tl development of such a democratic society—t restoration of communications between the Germa and the people of other countries, and the develo ment of younger leaders who know the world outsi of Germany—are steps no less needed in Austria ar Italy, as well as in all the countries where peop have been cut off from free and natural intercour with the people of other countries.

In addition to its regular European programm the Rockefeller Foundation in 1947 set aside 500,0 dollars for work in this field of European reconstru tion. The examples of these appropriations cited Dr. Fosdick indicate the challenge that the Found tion's work represents to Britain, which no less th the United States bears responsibility for administr tion in Germany. The sum of 120,000 dollars h been given to the University of Chicago to set up American faculty in the University of Frankfu From six to ten university professors from Chicag selected primarily from the field of the social scienc and the humanities, will be constantly in residence Frankfurt for periods of at least six months. grant of 60,000 dollars over three years to tl Germanistic Society of America is for the supp of scholarly periodicals to fifteen German and thr Austrian university libraries, and a grant of 25,0 dollars to Columbia University is intended to facilita the establishment of German radio as a public servi free from political control by bringing to Gre Britain, the United States and Canada, leadi German personnel from German radio stations acquaint them with the rights and responsibilities British, American and Canadian radio.

These are precedents which deserve to be mark and studied by the British Government and unive sities as well as men of science. As Mr. Kenne Lindsay has urged, it is a time to increase and not restrict, as has been done, for example, with bo imports, cultural relations of all kinds, at lea between those countries within the Marshall plan a the United States. To be fully effective, politic and economic organs must be matched with t acceptance of common values which in general ter must permeate the schools and the universiti Moreover, the universities carry a large measure responsibility for establishing a community of ide and ideals.

An important factor to both these ends is t interchange of teachers and students. That int change has been sadly interrupted during the pa year by travel restrictions, direct and indirect, a though the British Council is doing something in this field, as has been pointed out in *The Universities Quarterly*, its postgraduate courses for American and other overseas students at British universities are prohibitive in their cost for most students from European countries. Here it would seem is an opportunity for Government action to relax restrictions at least. Again, it may be asking too much of any one British university at the present moment to establish faculties in German universities on the scale which, through the Rockefeller Foundation, the University of Chicago has done at Frankfurt. But can nothing on these lines be done corporately by the combined universities ? Rather we might ask, can this country afford not to do so ? General Robertson has recently set up a Commission of eleven members, of which the Master of Balliol is the one British member, to examine the state of the universities and technical schools in the British zone in Germany. That Commission will function with essentially the same freedom as a Royal Commission in Britain and may be expected to address itself with wisdom and energy to the task of university reform. Its composition should dispel any fears that reforms will be recommended which break drastically with the past and the German idea of a university as a home of mature learning and research.

But if the German universities are to meet the demands which will be made upon them in the reconstruction period, if the younger teachers are to be enabled to take the part which they could usefully play in the government of academic life, if that isolation to which all observers bear witness is to be removed, interchanges on such lines must make a large contribution. Books and periodicals have their place; but the interchange of staff and of students is as important for the revival of learning and the development of the German universities to meet their new opportunities as it is for the presentation and interpretation of the constructive side of British policy and of the British way of life.

Significantly enough in the recent debate on Overseas Information Services that aspect of the question escaped notice, though it might well have been one compelling reason for the Government to relax some of the restrictions hampering such interchange if not for encouraging them by direct financial support.

Large as is the measure of responsibility resting upon the Government here the main driving force to action must come from the man of science and those nurtured with him in the universities who in those seats of learning have not only entered on the great heritage of Western civilization but have understood how great are the issues in the threat to liberty of thought, of investigation and of utterance in the modern world. In his passage dealing with the problem of Germany Dr. Fosdick crystallizes the essence of that challenge not only to Germany and Western Europe but also to the rest of the world, and he indicates some of the ways in which the man of science might work to overcome the lack of will and the lack of light by which, as John Masefield has warned us, 'one great land after another may be herded into a Dark Age in a very little time. The misuse and disuse of knowledge will only be averted as men of science answer that call, and, no longer content to enlarge the boundaries of knowledge in the laboratory, insist also on clearing the blocked channels of communication of knowledge and ideas, and seek to foster that cultural fellowship and intercourse in which the greatest and noblest elements in the heritage of the West find full and free expression.

REACTION KINETICS IN SOLUTION

The Kinetics of Reactions in Solution
By Dr. E. A. Moelwyn-Hughes. Second edition. Pp. viii+424. (Oxford : Clarendon Press ; London : Oxford University Press, 1947.) 25*s*. net.

WHEN the first edition of this book appeared in 1933, it was not generally believed that reaction kinetics in solution could be profitably interpreted on a molecular basis, and there was relatively little planned experimental work of high accuracy. The author then attempted to show that a simple kinetic picture would account for a large number of the observed facts, and the success of this attempt provided an important stimulus for later theoretical and experimental work on reaction kinetics in solution. The amount of such work during the last fifteen years is very large, and the task of producing a second edition of the book must have been a formidable one.

In many respects the new edition reflects the great expansion which the subject has undergone : thus it contains 144 tables of numerical data, and references to original papers by more than a thousand authors. It is an admirable feature of the book that the data for many reactions are examined in detail, with a clear analysis of possible experimental errors and complications due to reversible, competing and consecutive reactions. The book thus provides a valuable and critical guide to a large range of experimental work, including related topics such as reactions taking place at a liquid–solid interface, reactions in surface films, and enzyme reactions.

On the theoretical side it is no longer necessary to wage a crusade for the application of molecular kinetics to reactions in solution, and the task is rather that of conducting a comprehensible tour through the many alternative formulations and refinements which have arisen since 1933. Dr. Moelwyn-Hughes has given pride of place to a particular type of development, namely, the elaboration of the simple collision theory by adding electrostatic terms for the mutual interactions of ions and dipoles, the solvent being regarded as a continuous medium. This procedure produces at least the appearance of a quantitative theory, and the present book derives and compares with experiment a large number of electrostatic expressions. Unfortunately, most of these expressions contain one or more adjustable parameters which have to be derived from the kinetic data, and all that can be demonstrated is that these parameters usually have a physically plausible value. In these circumstances many would prefer to adopt a superficially more qualitative treatment, which gives a picture of the part played by the individual molecules of solute and solvent and avoids the use of a macroscopic dielectric constant of doubtful significance.

It is remarkable that the terms 'transition state' and 'critical complex' do not occur in an index with more than 700 entries, and that the quasi-thermodynamic method is scarcely used at all in the book. It is true that the statistical equations of the transition state method are worked out in an appendix, but (as the author himself points out) they are of little service in predicting absolute reaction-rates in solution. The value of thermodynamic analogy does not lie in detailed calculation, but in the insight which it gives into the parallel effects of various factors (temperature, pressure, solvent, etc.) on reaction velocities and on equilibria. This aspect of the matter has not been clearly dealt with, and the chapter on "Equilibria" is concerned chiefly with the reverse process of explaining equilibrium constants in terms of kinetic considerations. At best, this procedure provides a derivation of familiar relations which is cumbrous and of limited validity, and at times it produces some curious results, for example (p. 196), an expression for an electrolytic dissociation constant which involves the viscosity of the solvent. This chapter might with advantage have been curtailed, or even omitted altogether.

It is possible to criticize a number of the author's detailed statements; for example, that an observed reaction order of two shows the slowest step to be bimolecular (p. 49), and that the slowness of esterification reactions in the gas phase must be due to a low collision factor (p. 242). However, in spite of this, and the more general criticisms indicated above, the author has given a useful survey of much recent material. If he has at times failed to give a clear picture of its significance, this is due, at least in part, to the great bulk of experimental work, and to the many and diverse interpretations which have been advanced.

R. P. Bell

PROPERTIES OF SLOW ELECTRONS IN GASES

Electrons in Gases

By Sir John Townsend. Pp. viii + 166. (London: Hutchinson's Scientific and Technical Publications, n.d.) 25*s*.

DISCHARGE phenomena, which may be as varied as lightning, the operation of counters, or the growth of photo-electric currents, all depend upon the mechanics of electrons in gases. Any picture of those processes which involve electron and atom collisions must be built upon experimental determinations of such factors as the atomic cross-section and the fractional loss of energy in collision. Further, the related entities of electron-drift speed and energy of agitation, or temperature, and probably the process of attachment also, depend upon those factors through the electron-energy distribution function. This function depends upon the electric intensity, the gas concentration, and on the variation of atomic cross-section with velocity, and thus varies from gas to gas in a manner which, for any given case, is at present best found experimentally.

For this reason the subject-matter of "Electrons in Gases" is of fundamental significance. The experimental work described is mainly that carried out by Sir John Townsend and his collaborators in Oxford since the publication of his treatise "Electricity in Gases"; and the present book, which is a research monograph, makes an interesting sequel. The description of the determinations of the mean electron energies and the atomic cross-sections for slow electrons by the diffusion method is very useful, as this technique has proved to be powerful and of wide application. In the higher energy range the results are fundamental in discharge physics; but recent work on the interaction of radio waves in the ionosphere shows that the technique is also capable of giving important data in this field, where the electron energies are comparatively low and do not greatly exceed thermal values.

The book is confined mainly to giving the theory of the experimental methods and the results obtained: space does not permit full discussion of theoretical derivations of energy-distribution functions when considerable excitation and ionization occur. Except for a treatment of the electric spark at low pressures, other discharge phenomena lie outside the scope of the book: such applications have been treated in Townsend's earlier treatise and in later books on the subject by others. On the other hand, valuable data on the ionization coefficients in pure monatomic gases are given, and the book, which unfortunately lacks an index, can be strongly recommended to those engaged in research in this field.

F. Llewellyn Jones

PARTHENOGENETIC PATERNITY IN CENTRAL AUSTRALIA

Aranda Traditions

By T. G. H. Strehlow. Pp. xxii + 181 + 10 plates. (Melbourne: Melbourne University Press, 1947.) 17*s*. 6*d*. net.

IN the early days of the discovery of Australia by the whites, the aboriginals, or black fellows, were stigmatized as degenerate, treacherous and quite untamable. More sympathetic study of these people has, however, rather changed this uncompromising attitude, and once the language difficulty is overcome a far juster estimate of their character can be made. The author of this book was brought up in close contact with the Aranda, able not only to speak their language, but even to think in it. He is able, therefore, to describe their ceremonies and transcribe their chants and folk-tales accurately and feelingly, combining the point of view of the participant with that of the observer. Some previous students of the Aranda have not realized the extent to which the northern, western and southern divisions varied from each other, so that little generalization can be made as to customs and ceremonies as a whole. But by limiting the study to one area (in the first section of the book the northern Aranda area in Central Australia) the author is able to give a reasonably full account of the myths and religion of a strongly patriliniar group.

These myths are mostly brief accounts of the lives of totemic ancestors handed down by word of mouth by the old men to young initiates, usually on the occasion of a visit to the local spot where the *tjurunga* or sacred sticks and stones are hidden. By the power of their superior knowledge, the old men hold absolute authority in all matters of religion and custom, and there is no outlet for any creative impulse in the younger generation. Every possible site in the territory has already been assigned its own spirit or myth, and there is nothing left to the oung men but to follow the traditions of their ders—a stultifying state of affairs.

Mr. Strehlow gives a detailed account of the visit initiates to one of these sacred caves, an account hich recaptures the spirit of the occasion, and he llows this with a number of northern Aranda myths. is interesting to see various threads running through em all, or at least through the majority. For ample, the manner of origin of men from their temic ancestor, in these cases so 'patrilinial' as to spense altogether with any female intermediary, e sons being 'born' from the armpits of the father, if the original inventors of the myth were unwilling admit any possible claim on the part of women. nother point which is brought out is the hostility tween the original father and his sons, leading to oss cruelty and frequently even to cannibalism.

The second part of the book deals with the three anda sub-groups already mentioned, distinguishing e customs of each group, especially those connected th *tjurunga* and initiation ceremonies.

The third part is concerned with *tjuruŋga* ownership, arrels about which were frequent during the rformances of the sacred ceremonies. The term *uruŋga*, as differentiated from *tjurunga*, is very definite and covers at least eleven different items, jects of stone or wood, sacred ground paintings or en sacred chants. In this section the author gives ncise accounts of initiation festivals and also tails of the laws governing *tjuruŋga* ownership.

The photographs illustrating the book are rather all and not very clear, but nevertheless give a od impression of the scenes they portray. The ok itself is a valuable addition to our rather iguous knowledge of this interesting and diminishing ce.

K. RISHBETH

LTERNATING-CURRENT POWER TRANSMISSION

grandi linee di trasmissione d'energia
lcolazione elettrica. Per A. Dalla Verde. Pp. xi + 6. (Milano: Cesare Tamburini, 1947.) 1700 lire.

AT present, the all-important problems of power transmission are those relating to long-distance ergy transport and interconnexion of high-power tworks. Examples of the first class are transission from Norway to the Continent of Europe or Great Britain, from the Victoria Falls to the dustrial areas of South Africa, from Tasmania to stralia, from the Lower Danube to Central Gerany. In the second class the realization of a ropean Grid system is the most imminent.

Quantitatively, these problems resolve into the ansmission of total powers of the order of 1,000 to 00 MW. over distances of 600 km. and upwards. ansmission by alternating current at high voltage the method which has been most fully developed. is system has become commonplace at voltages up 220 kV. The maximum voltage at which extensive actical experience is available is 287 kV.—the volte used for transmitting power from the Boulder Dam Los Angeles. Sweden is constructing a 380 kV. wer line more than 600 km. long, and a 220 kV. e in France has been designed with the view of ilitating its conversion to 400 kV. in the future. progressing from 287 kV. to 400 kV., detail oblems relating to the conductors and insulators ve to be examined, such as corona losses, and transient voltages arising from switching or from natural causes.

Costs of transmission lines and apparatus rise so rapidly with voltage that every component has to be examined with the view of attaining maximum overall economy. The costs of the transmission lines themselves are so great that there is also incentive to study alternatives to the established three-phase, 50-cycle systems, such as D.C. transmission.

These generalities should make it evident that new authoritative work on electrical transmission is worth serious examination.

The appearance of an Italian treatise is specially opportune as Italy has done much individualistic pioneer work in electrical transmission at very high voltages, in conditions which demand the closest attention to economy. The volume under review deals with alternating-current transmission in seven main sections: fundamental line constants, electrical calculations of line characteristics, vector and circle diagrams, voltage regulation, static and dynamic stability of three-phase systems, and choice of the fundamental elements of a transmission system.

Two appendices—hyperbolic functions and symmetrical components—give an easy review of the mathematical aspects of the subject.

The treatise is remarkably clear and objective, and in the reviewer's opinion takes a very high place among works of the kind. There are minor blemishes in printing, and some of the illustrations are difficult to decipher; but on the whole it is a pleasure to read the book. It covers adequately all electrical aspects of alternating-current transmission, and enables any conscientious reader to design a high-voltage transmission line which would be both safe and economical. Even with the best guidance from books, it has to be recognized that special tests must be made on site before finalizing designs of transmission lines. Two examples illustrate this point. In the case of 70 kV. lines erected more than twenty years ago on the coast of French Morocco near Casablanca, early experience showed that no normal type of insulator would withstand the salt-laden atmosphere which provoked flash-over on such a scale that it appeared probable that the transmission project would have to be abandoned. A remarkably bold and successful solution was found by the local engineers, who improvised oil-filled insulators which saved the situation.

The second case is that of the British 132 kV. Grid lines, which were originally insulated in accordance with the requirements of the empirical formula $(U/15 + 1)$ = number of disks per chain recommended by Signor Dalla Verde. Even with 20 per cent additional insulation, which was provided for in the mechanical clearances, flash-over troubles were so prevalent during fog in industrial areas that the degree of continuity of supply was altogether inadequate. In this case the situation was saved by the use of specially shaped anti-fog insulators which a British firm had developed. The lesson to be deduced is that experience at lower voltages in Great Britain and at the same voltage in other countries proved insufficient warning of the electrical difficulties arising from our peculiar atmospheric conditions.

It is to be hoped that engineers will have an opportunity of bringing to reality some of the projects mentioned at the beginning of this review. Young engineers who may be interested in them could find no better guidance than that provided in Signor Dalla Verde's book.

C. W. MARSHALL

Chymia

Annual Studies in the History of Chemistry. Tenney L. Davis, Editor-in-Chief. Vol. 1. (Edgar F. Smith Memorial Collection, University of Pennsylvania.) Pp. xiv + 190 + 16 plates. (Philadelphia: University of Pennsylvania Press; London: Oxford University Press, 1948.) 3.50 dollars.

THIS handsome volume, which is a worthy memorial to the late Prof. Edgar F. Smith, well known for his publications in the field of the history of chemistry, contains fourteen articles covering various aspects of the subject. All but one are in English. After a foreword, the essays take up the subjects of Frederick Accum, C. A. Browne, an English alchemical poem, Thomas Thomson, French chemists about 1840, Mendeléeff, potassium chlorate in pyrotechny, the early history of calomel, the concepts of substance and element, the water controversy, Scottish alchemy, the Karlsruhe Congress, and Dulong. There are several plates, and the text is unusually well printed, which, with the attractive binding, makes it a pleasure to read the volume. It is proposed to issue a volume annually, and if further volumes are as good as the first, the editor-in-chief, Prof. Tenney L. Davis, whose own historical publications set a very high standard, may well feel satisfied. All concerned in the production deserve the thanks of chemists who are interested in the history of their subject. The series should be acquired by all chemical libraries, and is a notable contribution to scientific literature.

Chemical Synonyms and Trade Names

A Dictionary and Commercial Handbook. By William Gardner. Fifth edition, revised and enlarged by Edward I. Cooke. Pp. viii + 558. (Kingston Hill: Technical Press, Ltd., 1948.) 50*s*. net.

THE only satisfactory method of reviewing a reference book such as this is to make continued use of it over a period of time, for only in that way can its value really be determined. Following this course, the reviewer has been surprised at the frequency with which trade names turn up during the course of a day, and has been equally surprised at the completeness with which the dictionary has met all demands made upon it. Only very occasionally has it failed; for example, it makes no mention of sulpha drugs, such as sulphapyridine; but the constancy with which it succeeds makes its failure a notable event.

The book will prove of great value to all who have to deal with chemistry and chemicals, and its information is not confined to any particular field of chemistry but embraces all. It is well printed on good paper and is stoutly bound, as a reference book should be.

Organic Syntheses

An Annual Publication of Satisfactory Methods for the Preparation of Organic Chemicals. By R. L. Shriner, Editor-in-Chief. Vol. 27. Pp. vi + 121. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1947.) 13*s*. 6*d*. net.

TO the large number of organic chemicals for which reliable preparative methods have been given in this invaluable publication a further list of thirty-nine is now added. As typical examples may be mentioned 3,5-dimethyl-2-cyclohexen-1-one from acetaldehyde and acetoacetic ester, ethyl α-isopropylacetoacetate from isopropyl alcohol and acetoacetic ester in presence of boron fluoride, 3-penten-2-ol from magnesium methyl chloride and crotonaldehyd stearolic acid from methyl oleate, and tetraiodop thalic anhydride from phthalic anhydride and iodi in presence of fuming sulphuric acid. The stateme of directions and precautions, the bibliography f each preparation, and the printing of text a formulæ are all admirable and remarkably free fro errors. The cumulative index covers volumes 20–2

J. R.

The Rare-Earth Elements and their Compounds

By Prof. Don M. Yost, Horace Russell, Jr., a Asst. Prof. Clifford S. Garner. Pp. ix + 92. (N York: John Wiley and Sons, Inc.; Londo Chapman and Hall, Ltd., 1947.) 15*s*. net.

THIS little book on the elements of the rare ear group, or lanthanides as they are now calle contains chapters on (*a*) electronic structures a oxidation states, (*b*) magnetic properties, (*c*) abso tion spectra, (*d*) evidence for the existence of eleme No. 61, (*e*) separation of the rare earths, and (*f*) chem cal and physical properties of these elements. The is also an appendix on nuclear properties of the ra earth elements. Since the chapters noted above cov only 69 pages, it is inevitable that the subject-matt has been very much condensed, a fact more evide in descriptions of chemical than physical properti Apart from this limitation, the volume contains mu useful and interesting information about this gro of elements. The rare earths have received m attention from chemists following the discovery th some of them are formed directly or indirectly nuclear disintegrations. This book provides a use introduction to the study of a very interesting ser of the chemical elements.

Elements of Nomography

By Prof. Raymond D. Douglass and Asst. Pr Douglas P. Adams. Pp. ix + 209. (New York a London: McGraw-Hill Book Co., Inc., 194 3.50 dollars.

THAT a straight-edge laid across three coplan linear scales will serve to express a multiline functional relation between the indicated sc readings is obvious; if the linear scales are n uniform, more complex relationships can be de with. But the step from these simple ideas to t construction of the alignment charts used increasing in engineering, industry, business and other fields considerable, and demands skill in design a draughtsmanship as well as in orderly computati Profs. Douglass and Adams are anxious that t young nomographer should not try to run before can walk, that he should realize "how small a porti of his entire problem the theoretical solution rep sents". Thus they begin with a painstaking discussi of scales, occupying six chapters, before starting th discussion of the simpler alignment diagrams in series of nine short chapters, the last of which de with the hexagonal diagram for the relation

$$1/x + 1/y = 1/z.$$

There is a short chapter on the use of a circul nomogram for the relation $xy = z$, and a final lengt chapter on a variety of more complex alignme diagrams, wherein curved scales are employed.

The casual reader who merely wishes to learn little about nomograms would probably find the pa of this book too slow. But a novice with some stro incentive urging him to master the topic should pro from the careful and detailed discussion, with i valuable practical illustrations.

THE ROYAL SOCIETY SCIENTIFIC INFORMATION CONFERENCE

Introduction

THE Scientific Information Conference held by the Royal Society during June 21–July 2, which was attended by about a hundred and thirty delegates from organisations in the United Kingdom and thirty from the Overseas Commonwealth and the United States in addition to about a hundred observers, was the outcome of a recommendation passed by the Royal Society Empire Scientific Conference of 1946 to examine, in this way, the possibilities of improvement in existing methods of collection, indexing and distribution of scientific literature and of the extension of existing abstracting services.

The importance of the questions involved arises from the overwhelming mass of the literature, which is estimated to total anything up to one million published items a year, apart from the unpublished reports and memoranda which multiply within every scientific establishment and may locally be even more important. This makes it impossible for any individual to scan more than an infinitesimal fraction of what currently appears even within a limited field, or to be sure of finding retrospectively those references which are the most apposite to his own work, unless the indirect means of doing so are highly organised.

Various aspects of the problem have, over many years now, been receiving attention on behalf of the scientific worker through such bodies as ASLIB (a union of the Association of Special Libraries and Information Bureaux with the former British Society for International Bibliography), the International Federation for Documentation, the British Standards Institution and latterly the Technical Information Services Panel of the Committee on Industrial Productivity appointed by the Lord President of the Council. Much useful discussion is to be found in the published proceedings of the first two of these organisations; but along some lines of development—as, for example, mechanical methods of selecting literature references—the position reached is that inventors of machinery and documentary devices have progressed ahead of the ability of the users to tell them what they actually want done. Hence the value of a conference representing primarily the beneficiaries rather than the organisers of information services, and particularly of one at which the special problems that beset scientific men working at isolated posts overseas could receive their due share of attention.

The Conference was organised in four sections to appreciate and discuss what can be done to improve and rationalize the arrangements for:

(1) Publishing and distributing original scientific papers (Editor: Prof. J. D. Bernal).

(2) Issuing and using abstracts to convey current awareness of the availability and relevance of such papers (Editor: Sir David Chadwick).

(3) Consolidating abstracts or other forms of reference into continuously cumulative indexes and using these and other library services for the retrospective searching of the literature (Editor: Dr. J. E. Holmstrom).

(4) Producing and utilizing periodical reviews of progress in designated fields of science (Editor: Prof. H. Munro Fox).

The editors were appointed some months beforehand to take charge of each of the four sections, and they had, with assistance from others, prepared much material for consideration. Terms of reference had been drafted for forty-two specific subjects of study by sixteen working parties. At the opening plenary sessions of the Conference the background to these questions was explained by the editors and the membership of the working parties was made up, each consisting of six to eight persons having special knowledge of the groups of questions they were to answer. In some cases panels of consultants were also listed from which the working parties could co-opt additional members when considering particular questions. The working parties then met separately—except for a few joint meetings where the interests of several overlapped—until the final plenary sessions, when their conclusions and draft recommendations for action on each question were reported to the Conference as a whole for adoption, amendment or rejection. In this way altogether some seventy recommendations were finally sent forward by the Conference to the Royal Society, proposing positive actions either by the latter directly or through appropriate named organisations.

Section 1: Publication and Distribution of Papers Reporting Original Work

Section 1 of the Conference had to deal with the publication and distribution of papers containing reports of original work. Papers referring to this prepared for the Conference were essentially of two kinds: those setting out suggestions or expressing opinions, and those containing numerical and statistical information on publication and reading habits. In the first category were the group of papers on Prof. J. D. Bernal's proposed scheme for centralized distribution of scientific papers, criticisms of it by the Physical Society and by the editors of some biological societies, and comments on these views. In the second category were studies on the average length and scatter of papers in different periodicals, on the variety of formats in journals taken at the library of the Royal Botanic Gardens, Kew, on delays in publication; and lists were prepared, after consultation with societies, of the chief journals published in different fields in the United Kingdom and the Commonwealth.

In addition to these, the results of two surveys, one organised by Mr. Urquhart on papers inquired for at the Science Library, and the other of a special questionnaire sent out to research workers in Cambridge, the Department of Scientific and Industrial Research, Rothamsted Experimental Station, the Medical Research Council and various industrial firms. The steering committee of the Section eventually drew up a set of terms of reference for five working parties:

Working Party I/A: (i) To examine the present format of scientific publications and to make recommendations as to the adoption of suggested standards. (ii) To review methods of reproduction of scientific papers and to make recommendations as to the applicability of each.

Working Party I/B: To study the importance of editorial distribution and other factors in relation to the length of scientific communications and to make recommendations as to any desirable changes.

Working Party I/C: To consider whether any advantage would be gained from a more rational subject grouping of scientific communications within existing journals.

Working Party I/D: To consider the general question of the organisation for publication of original papers and the mechanism for their distribution, and to recommend any steps which may be taken through the co-operation of existing bodies towards achieving any desirable improvements.

Working Party I/E: (i) To examine the present causes of delay in publishing original scientific work and to make recommendations. (ii) To review existing difficulties in the availability of scientific information to men of science, and to make recommendations.

In order, however, to give greater coherence to the work of the Section, the first and last meetings of 'working parties' were joint working parties, and joint meetings of working parties of different sections were arranged on the subjects of photographic reproduction methods and classification.

At the opening plenary session on June 21, with Sir Alfred Egerton in the chair, short statements were made by the editors and the leaders of the working parties and a general discussion followed, with the purpose of conveying to the 'working parties' the views of the members of the Conference. On June 23 there was a special plenary session to consider the replies to the questionnaire already referred to, and to another sent out by Sir David Chadwick on abstract services.

The major conclusions of the questionnaires were of a very decisive character and modified considerably the type of proposals put before the Conference. The most important of these results was that emphasizing the large reliance of research workers on libraries, principally departmental libraries, three-quarters of their reading being derived from this source and the relatively small proportion of reading derived from journals subscribed to by the research workers themselves. It would appear that the average research worker looks through some nine papers a week and reads three carefully, making notes and usually keeping a card index. The paper was read, in 37 per cent of the cases, on account of a reference in another paper and only in 18 per cent on account of an abstract. Reprints furnished 6 per cent of the general reading, but 12 per cent of the careful reading. There were some significant differences between the reading habits of the different sections, those in the applied sciences reading on the whole fewer papers than their more academic fellow workers, and senior workers looking through more papers, but reading fewer carefully, than junior workers. The distribution of reading in various journals was significant: 2,000 papers described as carefully read during the course of the inquiry were derived from 430 different journals; but the distribution of papers consulted among journals varied enormously, one-quarter of the papers being found in six journals, half in thirty, and the last quarter in 330 different journals. This emphasizes a law derived by Bradford from studies of the actual distribution in journals of papers covering particular topics, and shows that his conclusions apply equally strongly to papers actually read. It is also notable that more foreign papers were read than British, and that the great majority of these were American. The major conclusion that can be drawn from these results is that, in the absence of any rational system of distribution of papers by subject, the libraries are the essential agents in the distribution of scientific publications.

The 'working parties' each held a number of meetings which were on the whole remarkably free from controversy, and came to conclusions and recommendations for the most part unanimously. The position of working party I/A was fortunate in that its chairman, M. Lemaitre, had just returned from a meeting of the International Standards Organisation at Geneva and was able to refer the Conference to resolutions already taken on the standardizing of the format of periodicals. The advantage of a limited number of sizes was admitted, and the resolution passed that once these standards were accepted societies would be urged to adopt them whenever they were changing their format. Similar considerations were given to the layout, particularly on such questions as the form of reference and the desirability of beginning each separate paper on a right-hand page to facilitate the issue of reprints and the division of the journal into papers for reference purposes. On questions of reproduction, it was agreed for the most part that printing is the most suitable for large numbers, but that new methods, particularly lithography and the diazo reflex process, might be increasingly used when small numbers are required. The 'working party' put its weight behind the general recommendation for further research on, and development of, methods of reproduction.

'Working party I/B' was on much more controversial ground in its study of the lengths of papers. While there was general agreement that too many papers of a repetitive nature are written, and that papers are longer than they need be, results incorporated in the general resolution of the Section, there was more discussion on the suggestion of extending the practice, already adopted by the Institution of Electrical Engineers and some other bodies, of issuing with the journal a full précis of a length from one-twentieth to one-quarter the original length of the paper, to be issued together as précis-journals covering a cognate group of sciences. The argument for such précis-journals was that they would provide digests of material lying outside the immediate field of any particular worker which would not, in fact, be read unless presented in this shortened form. The argument against it was that the proposal involved the issuing of still further publications and that the field would be covered as adequately by informative abstracts. The 'working party' finally agreed to put forward the suggestion for consideration by the proposed consultative committees of editors suggested by 'Working party I/C'. 'Working party I/B' further considered the need for making provision for the preservation and permanent availability on demand of copies of scientific documents and reports which are too long for publication in the ordinary way. It recommended that some system of deposit similar to that of the Science Service in the United States should be established.

'Working party I/C' was concerned with the grouping of scientific communications within existing journals. This question is very closely connected with that of the classification of science considered more particularly in the other Sections. It was recognized that the scatter of papers on essentially the same subject in journals is very wide; but the 'working party' did not feel competent to indicate precisely how it should be reduced. It is suggested, however, that this could best be done by the setting up of standing consultative committees of editors in cognate subjects, as is already the case for the Biological Council. These editors might by negotiation arrange among themselves what subjects fell properly within the scope of the particular journal, and which might equally well appear in a small number of journals. In the latter case some provision of exchange of lists of forthcoming papers might present the reader of any particular journal with information as to what is going on in his field far wider than he gets from the journals he can take and far more rapidly than he can get from abstracts. This 'working party' also considered the whole question of the formation of new journals or the extension and division of old ones. It concluded that the latter procedure is on the whole preferable, and that in any event it should not be penalized through the present control of paper supplies.

'Working party I/C' also dealt with two other questions of a more financial nature. It is clear that additional functions for editors, together with the responsibility of producing a paper in a better form (discussed above), would increase the work laid on them. It was recommended that means should be found to provide secretarial and other assistance to editors of journals, particularly smaller journals. The weak financial position of nearly all publishing bodies is clear from the proposal to extend the practice already prevalent in the United States of asking authors to pay for insertion of papers in journals ; this was supported by the 'working party' only in exceptional cases, while the Conference itself by a decisive vote was against requests for payment in any circumstances. This, of course, leaves the position exactly where it stands, and if rising costs are not to mean actual restriction of the amount published without regard to quality, the only solution can be through increased grants, either direct from Government or by some form of levy.

'Working party I/D' dealt with the very wide question of organisation of publication of original papers and mechanisms for their distribution. It was originally thought that this working party would deal with the detailed proposals of Prof. Bernal on reprint circulation ; but as he himself (as he explained), in the light of the questionnaire on the subject, considered that distribution through libraries is far more important than distribution to individual research workers, this did not come up for discussion. Instead the 'working party' concentrated on the means of obtaining separates directly from publishing bodies or by subsequent copying. The resolution as finally passed by the Conference, after emphasizing the importance of separates to scientific workers, called for a special exploration of the possibility of societies, libraries or commercial enterprises acting as agents for obtaining and distributing such separates. The question of copying separates, which is widely practised in individual cases, came up under the general question of copyright, at a special discussion at the Conference. 'Working party I/D' also emphasized the importance of library and information services, and particularly stressed the need for immediate Government action to provide for the enlargement of central scientific libraries and information services, and for providing for the effective functioning of these by an adequate staff having special qualifications in librarianship and science. It here made special reference to the Patent Office Library, the space in which has not been increased for many years, and to the Science Library. To increase the effectiveness of libraries it also proposed that library committees should co-operate to a greater extent than at present to prevent duplication.

'Working party I/E' had the task of exploring delays in publication and the availability of already published scientific material. It came to the conclusion that the best way of eliminating the former was by closer co-operation between the printing trades and the scientific societies, and in a resolution called on the Royal Society to organise a permanent liaison committee between industry and scientific publishing bodies. The technical means of more rapid publication by alternative methods, particularly lithography, were discussed and the matter referred to a proposed standing committee on the development of reproductive methods (referred to below). Another point stressed by this 'working party' and incorporated in the general resolution of Section 1 was the need to increase the speed of every stage of the process of the production of a scientific paper, beginning with its actual writing, and passing through its examination by heads of departments, its refereeing and the various stages of actual reproduction and correction. Delay at any stage was felt to have a psychological effect, increasing the probability of delay at other stages. As to availability, particularly in the Commonwealth, this matter was felt to be very largely one of discovery of the whereabouts of the material, and therefore depended on indexing and abstracting. Here proposals for the preparation of lists of titles and abstracts, particularly those emanating from Dominions and Colonies, were made and incorporated in other resolutions of the Conference.

In the general meetings of the Section many points were raised by different 'working parties' so interrelated as to make it desirable to include them in one general resolution. It was proposed that the Royal Society should initiate a vigorous and sustained campaign to improve the preparation and presentation of papers. This would involve action all along the chain of preparation, beginning with the research worker himself, who should be better trained than at present in the technique of writing and preparation of papers for publication. In turn, directors of research might be able to save very much editorial time and trouble at a later stage by careful pre-editing. Editors themselves, or the publication committees of their journals, were urged to take a more severe line than at present on the acceptance of papers for publication, eliminating so far as possible those that were merely repetitions with variations of papers appearing elsewhere, or those lacking in brevity or clarity of expression.

The recommendations of the 'working parties' were communicated to the plenary session of the Section on June 29, where they were subjected to lively but on the whole friendly discussion. They were for the most part, after certain amendments, accepted by the Conference as a whole, the only point of dispute being the question of the proposed précis-journals which, being a relatively new idea, certain of the delegates would have preferred to be omitted altogether from the resolution.

The full bearing of the recommendations of Section 1 can only be fully appreciated in relation to the general work of the Conference ; but it may be claimed that although no radical changes were proposed, the sectional recommendations indicate in a precise manner what should be done by other bodies to improve the production and distribution of original scientific material. The technical questions were appropriately referred to representative committees which have some reasonable chance of getting their recommendations accepted. On the more general issues of improved distribution of reprints and a more concentrated and more rational grouping of papers in journals, much will depend on how far it is possible in practice to set up effective working committees of editors who, with the greatest knowledge of their respective subjects, will be most able to set their particular house in order. It is to be hoped that members of scientific societies will also, as a result of the Conference, take more interest than they have in the past in the mechanism of publication, realizing that it is in their own hands to modify, and that it is not some divinely imposed order which they must accept without complaining.

J. D. BERNAL

Section 2: Abstracts and Abstract Journals

On the shelves of the Athenæum Club is a series of annual volumes, politely styled, "The Works of the Learned". The date of the first is 1699. They are informative abstracts, longer than those now usual yet true to type. Abstracts of scientific papers are certainly not new. Yet the decision of the Royal Society to devote one main section of its Conference to the consideration of abstracts and abstracting services is likely to prove timely.

The keynote of the Conference was service to science and to the scientific worker. Abstracts exist to serve the scientist. That is their sole justification. The English-speaking peoples are the chief producers of scientific abstracts. The journals of some of the United Kingdom abstracting services have appeared without a break for more than seventy years. The number of those services has increased markedly in the last twenty to thirty years. Yet this Conference was the first occasion on which representatives of most of those services had met together as a group to consider how far they were serving the needs of science as a whole, how their methods and techniques agreed or differed and in what respects such variations detracted from extended use of their journals and labours. What also was most certainly new was to have available at such discussions the assistance and criticism of scientific workers of most varied interests and of representatives from the Dominions overseas, from the United States and from the United Nations Educational, Scientific and Cultural Organisation. This alone ought to make this Conference worth while in the long history of abstracts; but what was really surprising came out in the early days of preparation for the Conference, namely, the almost complete lack of factual information about the existing abstracting services, and of how scientific men, in their differing circumstances and in their different branches of science and its applications, actually used abstracts and for what purposes. Was their chief purpose to provide 'current awareness', making speed of issue the prime requisite and their useful 'life' comparatively short? Or were they often consulted over periods of five, ten or even twenty years, in which event obviously good subject indexes, and where possible consolidated five- or ten-year indexes, were a great advantage? Was it broadly true that while an informative abstract is invaluable to the scientific worker far from a good library, as one working in a Colony, the indicative type of abstract generally meets the needs of anyone in the United Kingdom? Precise answers to such questions must vary in different branches of science, but are enough facts known to afford any general guidance or lead to abstracting agencies as a whole?

Opinions were numerous on how abstracts should be written, how indexed, on their type, on their excellence in some cases and failures in others, on their 'gaps' and 'overlaps' and on the difficulties in borderline subjects; but facts were few. This was inevitable, for surprising though it may seem, no list of the abstract journals published in the United Kingdom was readily available; consequently, no ready information on the branches of science and of its applications they, as a whole, presumed to cover. It is not suggested that any scientific men could or would have occasion to refer to all the abstracting journals. He knows one or two, and may at times be referred by his librarian to others; but if no ready information of their general coverage is available, he can scarcely be expected to refer to a journal the title of which may be vaguely familiar to him although he may be ignorant of its scope. The plight of a scientific man overseas wishing to use United Kingdom abstracts is greater.

Factual information had been collected from many of the abstracting agencies. This was presented to the Conference in condensed form, also the results of some inquiries into the use of abstracts. The Conference, however, realized broadly how the present services had grown up, their general character, the experience gained and knowledge orderly accumulated. It referred the whole subject to three 'working parties'; one to examine the place of abstracts in the service of scientific workers, their relation to other forms of service, such as reviews, bibliographies, etc., and to review the existing services; a second composed mostly of representatives of the abstracting agencies to compare their methods, techniques and practices; and a third to look to the future.

A paper presented by the Science Library, London, showed that notices in abstracts probably cause most inquiries for copies of original papers (possibly a third of the total), closely followed by references to papers in other papers. Prof. J. D. Bernal's pilot survey in Cambridge and elsewhere placed it lower at one-sixth. A small-scale but very welcome voluntarily organised inquiry in the University of Birmingham showed a preference of more than three to one for informative abstracts, and that about one-third of new papers were discovered through abstracts. Other information suggested that informative abstracts were more used in the United Kingdom than might have been thought. But all these inquiries were on too small a scale to give any reliable indications. Also, to be useful, they would need to be broken down according to the different branches of science and its application. A diagrammatic representation of the inter-relations of science and the scope of existing abstract agencies which Dr. H. J. T. Ellingham had prepared showed at a glance present gaps and overlaps. Gaps, time-lag and indexing were the chief subjects of complaint.

One fairly recent change in the type of user came out, arising from the extended use of science in organised industry. This is the increased reliance of many scientific workers on the 'information officer' for help in searching and in obtaining literature. The information officer thereby becomes another and constant user of abstract journals. Also, such are the extensions of the use of science in industry that many abstracting agencies may not have included these officers as users of their journals. Abstracts have always been designed to serve particular groups of scientific workers directly, and the various abstracting services look on their work from that angle; but as his tendency extends, consideration of the needs of hese information officers as potential users of their ournals becomes important.

As regards the abstracting services, the facts ollected brought out several points. Most of the ublished abstracts are of the informative, that is, nger, more detailed, type. *British Abstracts*, the rgest single service, are of the brief, or indicative ind. Nearly all are on a non-profit earning basis. his means that behind each is some sponsor society r department. It thus follows that the phrase abstracting agencies or services' cloaks many variaions of functions or duties. The functions of any gency are those laid down or approved by its ponsor society or department. These may be onfined to the preparation and issue of abstracts, as ith *World Abstracts of Medicine*; or, as with the ropical Diseases Bureau and the Commonwealth gricultural Bureaux, they may be those of centres f information entailing aid in preparing reviews, in btaining reprints or copies of papers, or translations r even in identifications. The issue of the abstract ournal then becomes one of several duties and not a ole function. The agencies are not thus all of one ype or origin, capable of easy recasting or reshuffling. hey differ in function, type, scope and finance. But hey all have this basal characteristic in common: ach has been called into being at the instance of cientific men, engaged in some branch of science r of its application, to serve their particular eeds; each is responsible to (and ultimately conrolled by) scientific men in its sponsor society or epartment.

In each case responsibility for the abstract journal ests on scientific workers trained in that subject. ontrol may become difficult in particular cases; but he identification of a service with those engaged in particular branch of science or of its application hould foster service of a type suitable to its needs nd the maintenance of quality and accuracy. This dentification of a service with a particular group arries a corollary. The primary loyalty or allegiance f any abstracting agency is to the scientific workers n its sponsor society or department. The Conference howed no desire to disrupt such associations, or to ubject them to outside authority, for the sake of a eneral uniformity. To have done so would have een to ignore differences between the needs of ifferent branches of science, and the fact that in some gencies overseas interests are active participants; et an indefinite increase in the number of isolated ndependent services must lead, in the ever-increasing nter-relationships of science, to overlapping and onfusion rather than to clarification. Responsibility o a particular group or branch is in no way incomatible with better service to science as a whole. The perative portions of the Conference's terms of eference to the third working party, that looking to he future, were then: "To consider and report, with ecommendations if desired, on the advisability, cost, rganisation and functions for a Council on Abstracting, not to centralize all abstracting, but as a continuing agency, to promote co-operation between abstracting services, the elimination of gaps . . ."

It was with this background of facts and ideas that he 'working parties' started on their labours. It was impossible in the few days at their disposal to solve efinitely all the points which arose. This was especially so in the second 'working party' where, for the first time, abstracting agencies had met to examine their methods. Differences undoubtedly existed. To adjust those so as to secure a wider use of their journals is a continuing task and not one to be settled in a few preliminary meetings. They therefore presented their findings to the Conference chiefly in the form of conclusions, rather than recommendations. The first 'working party' also presented most of its findings by way of conclusions. The conclusions and recommendations were placed later before the Conference, were discussed, passed, amended, or rejected by it. The leaders of the three 'working parties' were Dr. H. G. Thornton, Mr. B. Fullman, and Dr. G. M. Findlay; the recorders Dr. M. A. Vernon, Mr. J. Beak and Dr. B. M. Crowther. All 'working parties' had the help of representatives from the countries overseas and from the United States. Mr. J. B. Reid, of the United Nations Educational, Scientific and Cultural Organisation, brought to Working Party No. 3, looking to the future, the latest information on international developments.

The conclusions reached by the Conference should, if followed, improve the general usefulness of abstracts. A few only can be mentioned here. Some overlapping between abstract services is desirable, when the services cater for readers having different interests. Such overlap is distinct from duplication. For this reason a single set of abstracts produced by a central agency would not suffice for universal use. Publication of abstract journals, covering identical fields and directed to the same type of user, constitutes duplication and is to be deplored. The quality of abstract indexes is frequently unsatisfactory. Abstracting services, unless combined with an information service, as is often desirable, cannot be expected to answer specific inquiries on literature. By way of comment on this point, it may be explained that this conclusion merely reflects the differing functions of these services, as already explained. All realized that the usefulness of abstracts is gravely impaired if the means for obtaining copies of the original papers are inadequate. This question kept reappearing in all sections of the Conference, and is undoubtedly one of prime importance.

Among the recommendations was a strong emphasis on the need for comprehensive subject indexes to be provided with each volume; and a recommendation that consolidated subject indexes be provided at intervals. But the chief recommendation adopted by the Conference was that on co-operation in the future. It was to the effect that the Royal Society be invited to consult the abstracting agencies to set up a standing consultative committee of abstracting organisations for mutual exchange of views and generally to promote co-operation. The Committee should consist of representatives of bodies responsible for the production of journals of abstracts. It should work on a voluntary basis and the cost be kept low. Among earlier matters for its attention were listed, increasing uniformity in the services in the methods of bibliographical citation, the maintenance of a comprehensive list of journals of abstracts, the question of its publication and the possibility of including in it an indication of the general scope of each journal, the possibility of co-ordination of systems of indexing, the determination of fields where readers' needs are inadequately met, and the maintenance of a panel of abstractors with special linguistic knowledge.

If this standing committee is formed—and all the main abstracting services were in favour of it—many questions besides those tabulated will come before it, though those when worked out should greatly extend the knowledge and usefulness of abstracts. Not only will this be the first time that these agencies have met to exchange information and experience, but also such meetings and consultations will have a definite object, namely, to promote co-operation in the service of science generally. An aim has been given. This recommendation may thus become among the most constructive from the Conference in this Section. It is certainly timely, in the light of the increase in the number of these services, the increased efforts in applying science, the general stir for better organised dissemination of information and the revived interest of the possibilities of co-operation on the international level. On this the Conference, while recognizing the difficulties, urged organisations covering similar fields to make efforts at closer collaboration.

The conclusions and recommendations of the Conference in this matter of abstracts may not seem so wide or so drastic as some might have wished; but though much testimony was given to the utility of present services, the striking characteristic of the Conference was this—no question was approached from a particularist point of view. The obvious desire of all was to secure better service to the scientific worker; to build on what had been learnt, but to harmonize and adapt it so as to be even more effective in the service of science. The long history of abstracts to meet the needs of science is not closed—perhaps, indeed, a new phase is opening; the particular services will continue, for the needs of scientific men in different branches and in different circumstances must vary. But while preserving all that is most useful in that respect, conscious collaboration in the interest of science as a whole will constantly grow, so that the journals become more widely known, more easily used, borderline cases provided for, and needless diversities of practice eliminated.

In all this the visitors from overseas played an active and stimulating part. When discussing abstracting, the needs arising from one's own local conditions and circumstances are apt to be so prominently and even fatally in one's mind as to distort the conception of what must be in some degree a general and not an individual service. The overseas delegates helped to keep this needed balance.

DAVID CHADWICK

Section 3: Indexing and other Library Services

Whereas Section 2 of the Conference was concerned in securing awareness of current publications, Section 3 dealt with the provision for retrospective searching: the problem of how to dispose literature references in such a way that those among them which may help to satisfy any particular quest for information liable to arise in the future will be turned up, when the time comes, with certainty and speed.

This problem includes what is normally understood by librarianship, and also goes far beyond it in magnitude and complexity. A librarian in the traditional sense is occupied with the procurement, store-keeping and cataloguing of books as complete units; but not with analysing their contents or indicating their relevance. Yet a single book, journal article or patent specification may touch on many subjects and be important from many points of view; and the mere fact that a library which holds a copy of it has catalogued it under its author and title, or even under such multiple subjects as may be implicit in the title goes only a very little way towards what is required. The problem of documentation is, in fact, to ensure that when a scientific man needs to find out what has already been done and thought regarding any topic whatever, he can quickly be given the most apposit references not only among the hundreds of thousands collected in his own departmental library but also among the millions available to him, by way of loan or photo copy, from the libraries of the world a large.

Any one of these may turn out to be the one which would best serve the interests of some future inquirer if only he knew of its existence, by enabling him to begin his own researches from a more advance starting point. There being no means, however, o foreseeing which item that will be, there are neede economical techniques for the mass processing of the greatest possible range of literature references to mee the contingency that any one of them may be of value. Fundamentally, there are four ways, each with its variations and its advantages and disadvantages, along which this central problem can be attacked:

(1) Indexing the names of subjects in alphabetica order. This is the usual system in books and at the end of each year's run of a journal; under certain conditions it is satisfactory also for card indexing But it involves many more difficulties and moot points than are apparent at first sight. It has the effect of dispersing logically contiguous items according to the letters of the alphabet with which their names happen to begin, and as the names are not standardized so as to make them mutually exclusive, a searcher is liable to look in vain for something which the indexer has buried elsewhere under a synonym.

(2) Classifying the subjects themselves under symbols which serve to pinpoint their positions in a logically constructed map of knowledge. Many such classifications are in use, some locally for special fields of subject-matter and some general like the Universal Decimal Classification, which is an internationally standardized extension of the Dewey system developed by librarians for shelving books. On this system, knowledge as a whole is divided into ten primary branches each denoted by a first decimal number, each of these into ten subdivisions denoted by a second decimal, each of the latter into ten sub-subdivisions denoted by a third decimal, and so on to whatever degree of particularization is required. As the sequence of subjects is ideographic, not alphabetic, an alphabetically arranged key (corresponding to the gazetteer in an atlas) is necessary for locating subjects when only their names are known.

(3) Coding the subjects under symbols which can be represented by patterns of holes punched in a card, or by patterns of dots detectable by optical means alongside a microfilm of the document under reference. Items so coded can be stored in random order and run through a machine, when required, which automatically picks out those of them which have been coded in any particular way.

(4) Coding the shapes of certain classes of objects under symbols which can be treated as above. The Dyson and the Gordon–Kendall–Davison systems of chemical notation enable this to be done for the arrangement of atoms in a complex molecule, which makes possible the mechanical selection of references to chemical compounds according to their molecular structures.

As staff and resources for bibliographical work are limited, the application of any of these methods must be governed by a proper balance of time and effort between indexing or classification on one hand and searching on the other. The greater the chance of references of a given kind being of future interest, the greater the justification for the labour of analysing them minutely and of consolidating those of different dates and sources into a single cumulative index. Where, however, a subject is unlikely or seldom likely to be of interest, it is more economic to rely on making an *ad hoc* search if and when the occasion for it arises, even though this may involve the tedious job of consulting the separate annually published indexes of many separate journals in which references might be found. Elaboration of indexing is, in fact, an insurance, and just how big a premium it is worth must depend on circumstances.

Two of the working parties in Section 3, dealing respectively with classification and with mechanical methods, drafted recommendations which the Conference adopted on various practical aspects of this central problem.

The Universal Decimal Classification, it was held, has both advantages and limitations. Among its assets are the millions of existing references so classified and the many thousands being published every year with the class numbers already printed on them; these are among the justifications for continued extension in its use. But the criticisms to which it stands exposed were recognized also and led the Conference to favour setting up a standing committee for fundamental research into subject classification of science without pre-commitment to any particular system. Further study and research on alphabetical arrangement were also recommended.

Similarly a full-scale experiment on mechanical methods of selection was urged, as well as encouragement of the Aslib committee which is studying and collating progress in this field. A particular device, exhibited at the Conference, which the working party found of interest though no positive recommendations was made about it at this stage, was the invention of Dr. J. Samain of Paris: this has a typewriter-like keyboard whereby up to 24 six-letter words can be punched directly in a single card, and a selector able to pick out those cards which carry any desired word or combination of words regardless of the position or sequence in which these occur on particular cards.

On the question of chemical notation suitable for punching on cards, the Conference recommended that the attention which appropriate bodies are giving to one system be extended also to others proposed.

Another working party studied photographic and other new methods of reproduction. These have many important uses in bibliographical work, and the Conference recommended the establishment of an advisory committee to stimulate and watch developments in Great Britain and in other countries. As an example, it is an obvious economy if index items or abstracts which are required to be circulated sequentially in page form and also to be cumulated separately in card form can be reproduced in both forms without having to typeset or typewrite them (and check them) twice over. In the United States this is now widely practised. Another recommendation of the Conference which depends for its economy on suitable methods of reproduction was the issue from a central source of guide cards bearing Universal Decimal Classification numbers, for insertion direct into card indexes instead of having to copy them locally from a list. Again, in the United States the Library of Congress issues printed catalogue cards for all the books it handles, which hundreds of other libraries can use instead of having to do the work over again locally. Steps to develop such a service in Great Britain were recommended.

Among the new methods of reproduction studied and commended by the Conference was a Dutch process of diazo-printing (much cheaper than photography using silver chemicals) which enables not only direct copying from single-sided translucent originals but also, by a reflex method, copying from double-sided or opaque originals including the pages of bound books. This system has the further immense advantage that processing of the exposed paper is dry (or practically so) and therefore instantaneous, so that one or many copies of any document can be obtained, as and when required, in an ordinary office.

Various questions affecting the use of microphotography were studied, including the supersession of continuous lengths of film by strips or other more convenient units. Apart, however, from technical points like this, the great possibilities latent both in microphotography and in full-sized photo-copying for assisting the dissemination of scientific literature are governed more than anything else by restrictions resulting from the present copyright law. To give only one instance: if these could be removed by legislative reform, or circumvented by some form of agreement with authors' or publishers' organisations, the production and distribution of separate offprints of articles printed in journals would be greatly facilitated. The copyright question was discussed by the Conference at considerable length, and a recommendation was put forward stating the necessity for the provision of single copies of extracts from books and periodicals for purposes of scientific research and inviting the Royal Society to initiate action in the matter.

A fifth working party, which considered data tables, reference books and guides to information services, compiled a useful bibliography of these works. The Conference recommended continued action to ensure that scientific compendia in all fields of science were available and up to date, and to assist their publication where necessary. Financial aid to speed a new edition of the "ASLIB Directory" was urged, and a hope expressed that the "World List of Scientific Periodicals" might be re-issued as early as possible. The Conference recommended compilation of a British work corresponding to "Industrial Research Laboratories in the United States and Canada", and also of a subject index to the research activities and specialized knowledge of individual men of science.

Some 40 per cent of the world's scientific publications are in languages other than English; hence the importance of the questions referred to the sixth working party of Section 3, which considered translation services. As a result of its labours the Conference recommended greatly increased publicity for the ASLIB Register of Specialist Translators, which enrols only persons who combine linguistic knowledge with knowledge of particular branches of scientific or technical work; also its extension to those qualified to act as interpreters, by the simultaneous method, at international scientific conferences. Other recommendations included the institution of university or other suitable diplomas in translating and interpreting, the establishment of a central location index to unpublished translations, and that the Government be asked to consider action to modify the Berne Convention on international copyright so as to allow organisations such as the Science Museum Library to make available any translations deposited with them.

J. E. Holmstrom

Section 4: Reviews and Annual Reports

Reviews of a critical and constructive nature, written by leaders in particular branches of science, are of the greatest value, and senior investigators should regard the production of these as an important ancillary to the pursuit of new knowledge. The fields covered by critical reviews depend upon the first-class reviewers available at any given time. Such reviews, written by specialists, can be made very informative to workers in allied fields by the inclusion of an introduction and conclusion of a general, and as far as possible non-technical, nature. The desirability of the inclusion of the titles of papers in the bibliography of reviews and other scientific papers varies with the science; it is desirable in biology, possibly less so in chemistry.

Annual or biennial reviews, progress reports and books on recent advances serve a useful purpose, especially if prepared as critical reviews rather than synoptic summaries. Reviews written by specialists for workers in other branches of science are of great importance and at present are insufficient. In the applied sciences there is also a need for more review publications. In this connexion considerable material could perhaps be made available for publication by the larger industrial concerns.

Reports on 'symposia' are recognized as a valuable contribution to the recording of progress in science but are not a substitute for reviews or annual reports. A wider distribution of copies of the more important review lectures is desirable.

H. Munro Fox

THE PALESTINE FLORA

By ERIC HARDY

THE trouble in Palestine sets back the clock on the recent efforts of both Arab and Jewish gardeners to develop the horticultural attractions of the Holy Land, for the palm boulevards of Jaffa, and the flower-growing settlements at Mishmar-Hasharon, etc., had attracted much praise and attention. The danger, however, goes deeper, for modern Palestine was not the primitive wilderness of brigand and bedouin as depicted in most of the Western religious books. Several excellent gardens and plant collections were in the country, and their future is threatened by the bitterness of war. There is, for example, the best of the attempts to create a typically English garden, with its lawns and roses, its rockery and its pergola, which was in the grounds of Government House on the dry and dusty hill outside Jerusalem. On besieged Mount Scopus the botanical department of the University of Jerusalem housed the finest herbarium of the Near East flora, with more than 300,000 sheets of specimens collected not only in Palestine, but also in Syria, Arabia, Transjordan, and in particular the desert regions. There was also the private collection of Palestine and Transjordan plants collected in the American Colony in Jerusalem by J. E. Dinsmore, editor of the second edition of Post's "Flora of Palestine and Syria", where also the garden of a score of varieties of Palestine irises was a famous feature in April. Another internationally famous private herbarium, the largest outside the University, is the Herbarium Boyko, housed at the village of Talpioth, between Jerusalem and Bethlehem, in the home of Dr. Hugo Boyko, its compiler, an official of the Mandatory Government's Department of Forests.

At Rehovoth, which has been subject to several air raids, are housed the laboratories, collections, trial gardens, etc., of the country's main horticultural research. Here Dr. Oppenheimer, Dr. Samech and others maintained the vast organisation of the citrus research and the fruit-growing industry, where East Malling ideas were developed and plants acclimatized and tested. The horticultural edition of the *Palestine Journal of Botany* is produced here under Dr. Oppenheimer's editorship, while the purely botanical edition is produced at the University of Jerusalem under Prof. Zohary's editorship.

In recent years the University of Jerusalem had established a botanic garden on Mount Scopus, mainly for shrubs and trees typical of the country's flora, and including a coppice of cedar of Lebanon. Under the Mandatory Government, the Departments of Forests and Agriculture maintained several stations existing from Turkish times, like the vineyards, date palms and orchards at the old Turkish horticultural station in Jericho, and they established others. Near Acre the Mandatory Government established its main stock farm and horticultural and field crop station; its station for deciduous trees, carobs, vines and pruning instruction was near Safad. At Farawana, near Beisan, in the middle Jordan Valley, it had a station for sub-tropicals, olives, vines and dates; another near the historic Jacob's Well at Nablus for olives, vines and pomegranates; an experimental station for miscellaneous work was at Majdel, and a forestry station at Gaza that has been planting a large acreage of wind-blown sand with tamarisk to check the inroads of the Sinai sandstorms. From these stations, Arab gardeners were taught Western ideas of grafting and pruning, particularly for olive cultivation. The famous Arab olive orchards at Beit Jala near Bethlehem, and their pomegranate orchards near Ramallah, were a tribute to the work.

On the cool and fertile shores of southern Galilee, the Jews maintained a remarkably interesting nature study and agricultural institute called Beth Gordon, in memory of a pioneer settler, Aaron Gordon. This was at Degania settlement, in the vicinity of much of the recent fighting between Tiberias Jews and the Iraqi Army. Beth Gordon (or Gordon House) was open to any visitors interested in natural history or horticulture irrespective of membership. It maintained laboratories, lectures, a card-indexed library of 12,400 books in several languages, a museum with 18,500 animal specimens and a herbarium of 3,400 named plants, all under the direction of M. J. Palmoni. This was mainly a teaching centre, whereas Rehovoth was the main centre of horticultural research and plant acclimatization.

For several years the European colony in Jerusalem maintained a Jerusalem Horticultural Society, and in 1928 it published an instructive little booklet on the cultivation of gardens under those high, dry, chalky conditions. But war has sapped much of its energy and activity. The municipality of Jerusalem had initiated a few excellent little public gardens in recent years, gardens of begonias, *Lantana*, *Iris* and a strange mixture of Western formality and sub-tropical flowering shrubs, together with a small nursery for re-stocking these gardens, placed at the foot of the Mount of Olives.

It is true that in recent years Palestine-grown flowers were on exhibition in London and at Detroit; but Palestine has nothing to compare with Egypt's famous Gardens of the Nile near the Delta barrage. Jerusalem is a difficult place for the gardener, as its high position entails a seasonal variation from almost sub-tropical summer to winter snows and frosts. But since the mandate the temperature of Jericho in the hot lower Jordan Valley has been made much cooler for its inhabitants by the extended cultivation of trees, for both their floral effects and their fruit, irrigated with the sparkling waters of Elisha's spring. The first cultivators of the Jericho desert were the Greek monks, whose monastery orchards adjoining the tamarisk thickets just north of the Dead Sea are several hundred years old. In more recent years the Jewish settlement at Beth Ha'arava, beyond the recently destroyed Palestine potash plant on the north shore of the Dead Sea, 1,300 feet below sea-level, has cultivated a former salt-desert by leaching the soil with pipe-borne sweet water pumped from the nearby Jordan. The French Trappist monastery at Latrun, scene of bitter fighting for the Jerusalem–Tel Aviv highway, has developed some of the finest vineyards and orchards in the country, and its wines are nationally famous.

The main problem facing horticulture in Palestine was lack of water; but in recent years I saw how much of this difficulty had been conquered by the establishment of concrete aqueducts in the middle Jordan Valley, pumping sweet-water on to the Dead Sea salt-lands, and damming up by earth and concrete reservoirs the occasional but heavy winter rain that filled the wadis in the southern Negev desert. Artesian wells were much used in the coastal area, where practically all the great citrus-growing orchards were cultivated; but a generation or two ago, sandy wastes covered this area.

The pomegranate, the vine and the fig were already under cultivation by the native Arabs when the ancient Israelites first invaded the Holy Land. The Israelites introduced the apple, the first fruit to be mentioned in any historical writings, for Ramsis II had planted this native of the Black Sea in his gardens in the Nile Delta. The Jews traditionally introduced the citron to Palestine from their Babylonian captivity, and the Arabs are said to have brought the lemon and the orange to the Mediterranean coast from Iraq in the tenth century. Modern research into the history of the citrus fruits has, however, shown that oranges and lemons were known in Palestine in Mishnaic times, and the coins struck by Simon Maccabæus shortly after he conquered Jaffa in 136 B.C. show the citron was then in cultivation there.

The Western world has been indebted to Palestine for many of its irises. I have seen iris Grant-Duffii, the laurel and *Lilium candidum* growing wild in the Carmel area. The profusion of the garden anemone, *A. coronaria*, *Cyclamen persicum*, *Tulipa montana*, *Narcissus Tazetta*, the golden *Sternbergia aurantiaca* and of *Cistus* shrubs has borne offspring to grace countless gardens in Europe and America.

OBITUARIES

Profs. Friedrich Oltmanns and Adolf Pascher

SOME tribute should be paid to Profs. F. Oltmanns and A. Pascher, both of whom died in 1945 after making substantial contributions to the advancement of algal studies during the present century.

The name of Oltmanns, who for many years occupied the chair of botany in Freiburg in Baden, will be remembered as that of the author of the first comprehensive account of the Algæ. His "Morphologie und Biologie der Algen", published in 1904, constituted a landmark in the study of the Algæ and, by making available an authoritative account of the group, stimulated and had a far-reaching effect upon algal investigation in many different directions. The more extensive second edition, which appeared in 1922–23, was less inspired, and its utility was marred by the inadequate and frequently erroneous literature citations. The extensive treatment accorded to algal biology in the third volume failed to give a clear insight into the many outstanding problems.

Oltmanns, however, has other claims for inclusion among the outstanding algal workers of his period. He was the first to elucidate clearly the role of the auxiliary cells in Florideæ, and we owe to him considerable contributions to the knowledge of the Fucales and of the conditions of life of seaweeds. A special volume of the *Zeitschrift für Botanik*, which he edited for many years, was published in 1930 when he reached the age of seventy years.

Pascher, who was born in 1881, spent the whole of his academic life at the German University of Prague, where, during the latter part of his life, he occupied the chair of botany. His influence on algology was of a different and more profound nature than that of Oltmanns. One of his earliest researches, published in *Bibliotheca Botanica* in 1907, was concerned with the morphology and behaviour of the swarmers of diverse filamentous Chlorophyceæ. It was probably these studies that aroused his interest in flagellate organisms, to the knowledge of which he was to make so great a contribution. His investigation of the rich flagellate and algal flora of the Central European uplands extended over a period of more than thirty years, and resulted in the description of innumerable genera and species new to science.

An early outcome of these studies was the recognition of the fact that flagellate groups like the Chrysomonadineæ and Dinoflagellata (Peridinieæ) include also coccoid and filamentous types, comparable to those already known among the Chlorophyceæ and Xanthophyceæ (Heterokontæ), though Klebs in 1912 had already to some extent advanced this point of view for the Peridinieæ. In the brief memoir entitled "Ueber Flagellaten und Algen", published by Pascher in 1914, however, the Flagellata as a whole were placed in their correct relation to the Algæ, and the theory of the flagellate origin of Green and Yellow-green Algæ, first propounded in 1901 by Bohlin, was extended to the new classes Chrysophyceæ and Dinophyceæ. Emphasis was also laid on the remarkable degree of parallelism evident between the various algal series emanating from flagellate sources. These diverse theses were more fully elaborated in a series of papers published during the next twenty years, dealing with Chrysophyceæ, Dinophyceæ, and Xanthophyceæ, in which fundamental knowledge of each class was appreciably extended.

The great debt which botanical science owes to Pascher is the elucidation of the diverse lines along which algal evolution from flagellate stocks has taken place and of the definite pattern followed in this evolution. His numerous papers, however, include many other important contributions to the knowledge of Protista. Outstanding among these are the extensive studies of amœboid and rhizopodial forms of Algæ, which first disclosed clearly the significance of amœboid organisation, the exposure of the manifold relations between pigmented and colourless flagellate organisms, and the recognition of the affinity between Diatoms, Chrysophyceæ and Xanthophyceæ.

Later generations will no doubt also acknowledge the debt owed to Pascher in respect of the publication of the "Süsswasserflora", which probably gave an even greater stimulus to freshwater algology than did Oltmanns' book. Pascher's own contribution to this series of volumes was very considerable, and includes some of the most valuable parts. It is much to be deplored that he did not survive to produce a second edition of the volumes dealing with the Flagellata, of which he had so unrivalled a knowledge. His last comprehensive publication was the volume on Heterokontæ in Rabenhorst's "Kryptogamenflora", which was completed in 1939.

Pascher's numerous papers are characterized by lucidity and by the excellence of the accompanying illustrations, although sometimes a little marred by hasty editing. Most of his work was published in the *Archiv für Protistenkunde* and the Beihefte of the *Botanisches Centralblatt*, of both of which he was editor for a long period of years. His was a lovable, though sometimes rather impetuous, personality.

F. E. Fritsch

Mr. H. Brearley

Mr. Harry Brearley, the inventor of stainless steel, died on July 14 at the age of seventy-seven. A native of Sheffield, and the eighth child of a family brought up in "Ramsden's Yard", of which he has given a vivid account in a delightful autobiography, "Knotted String", he had only an elementary school education and then worked as a cellar lad in a crucible steel works. He was fortunate in being taken from this to be a laboratory boy under a capable and kindly analyst, who persuaded him to attend evening classes. He married young, and quite early collaborated with Fred Ibbotson in a book on the analysis of steelworks materials. In 1914 he went to Riga, then a Russian town, as chemist in a steel works associated with Messrs. Firth of Sheffield, where he improved the technique of hardening armour-piercing shells, having also to act as managing director when the Russian Revolution came and many members of the staff left. On returning to Sheffield he took charge of the Brown–Firth Laboratory, installed jointly by two neighbouring firms. Difficulties in the making of armour plates led him to the further study of the thermal treatment of alloy steels.

His introduction of a steel containing chromium with low carbon was intended to provide a more durable lining for gun barrels, and it was the observation that specimens in the laboratory, under certain conditions of heat treatment, were highly resistant to corrosion that suggested their use for cutlery. A Sheffield firm, R. F. Mosley, produced knives made of this steel which were not stained by fruit acids or similar solutions. Difficulties arose over the ownership of the invention, and in 1915 Brearley left the firm and joined Messrs. Brown Bayley, also of Sheffield. For a time, the patents were controlled by a special organisation, the Firth–Brearley Syndicate. Patent litigation involved a visit to the United States. Brearley retired in 1925 to Torquay. He and his brother devised the method of studying ingot structure by casting and sectioning wax models. He was awarded the Bessemer Gold Medal of the Iron and Steel Institute in 1920.

Without a university training, Brearley had a remarkable command of lucid English, and his books are models of their kind. A man of sturdy independence, a lover of good literature, and a metallurgist who rendered great services to the steel industry and to the men employed in it, he has a strong claim to be remembered among pioneers in industry.

C. H. Desch

We regret to announce the following deaths:

Dr. William Cullen, well known for his work in mining engineering and explosives, on August 14, aged eighty-one.

Prof. Beatrice Edgell, emeritus professor of psychology, Bedford College, London, on August 10, aged seventy-six.

Dr. Alexander Smith, assistant mycologist at the Ministry of Agriculture and Fisheries Plant Pathology Laboratory, Harpenden, on July 23, aged fifty-four.

NEWS and VIEWS

Chair of Entomology, University of Illinois: Prof. G. Fraenkel

Dr. G. Fraenkel, lecturer in physiology in the Department of Zoology and Applied Entomology at the Imperial College of Science and Technology, London, has been appointed professor of entomology in the University of Illinois, Urbana, Ill., to take charge of the newly founded sub-section of insect physiology. Dr. Fraenkel, who was educated at the University of Munich, was an assistant in the Department of Zoology in the Hebrew University, Jerusalem, during 1928–30. During 1931–33, he was *Privatdozent* in zoology in the University of Frankfurt. From 1933 onwards, he has carried out research in insect physiology and the orientation of invertebrates at University College, London, and the Imperial College. Dr. Fraenkel has held his post as lecturer in physiology in the Imperial College since 1938. Most of Dr. Fraenkel's researches have been confined to insect physiology, including reflexes, pupation hormone of flies, function of halteres of flies, properties of cuticle and respiration. Since 1940 he has made a comprehensive study of insect nutrition supported by the Royal Society and, later, by the Medical Research Council. During the spring and early summer of 1947 he was guest professor in the University of Minnesota, where he gave a course of lectures on insect nutrition.

The National Radium Trust and Commission

With the coming into force of the National Health Act on July 5, the affairs of the National Radium Trust and the Radium Commission are being wound

p. The two bodies were established by Royal Charter issued under Letters Patent of July 25, 1929. The functions of the Trust were primarily to augment the supply of radium (and later, by supplemental Charter, other radiotherapeutic apparatus) for use in relation to the treatment of the sick in Great Britain" and "the advancement of knowledge of the est methods of rendering such treatment". The main duty of the Commission was "to make arrangements for the proper custody, equitable distribution, and full use of the radium . . . of the Trust with the object of promoting the treatment of the sick . . . and o make such arrangements for the supply on loan of the radium . . . as are necessary". When the Commission started work it was generally admitted that radium treatment in Great Britain had not ttained the standard then reached by such centres as the Fondation Curie and the Radiumhemmet. During the last nineteen years, however, some of the ational (university) radium centres set up by the Commission have achieved a reputation equal to the best anywhere in the world. At the same time, the standard of radiotherapy in general has been raised y the policy of centralization pursued by the Commission. Hospitals with small radiotherapy departments have been advised to make agreements with national centre for the treatment of their patients, nd the formation of small independent centres has been consistently discouraged. The present health organisation requires that the work hitherto done by the Trust and the Commission shall in future be undertaken partly by a Ministry of Health committee, nd partly by the regional hospital boards. It is deemed advisable, therefore, that the radium and other radioactive substances, apparatus, appliances, funds nd property belonging to the Trust and the Commission shall be dealt with by vesting them in the Minister of Health, or the Secretary of State for cotland, as may be appropriate. The Royal Charter and the three Supplemental Charters are to be surrendered.

Market Research

THE report of the Conference arranged by the Manchester Joint Research Council in Manchester on October 22, 1947, on "Market Research", has now been published (Manchester Joint Research Council. Market Research : Report of the Conference held on Wednesday, October 22, 1947, at the Albert Hall, Manchester. Pp. 108. (Manchester: Manchester Joint Research Council, 1948.) 2*s*. 6*d*.). It includes the full text of the three papers "The Technique and Applications of Market Research", "The Investigation of Trends of Consumer Tastes" and "Market Research and the Seller" submitted by Mr. O. W. Roskill, Mr. L. R. England and Mr. D. S. F. Vernon, respectively, together with their statements in presenting these papers and reports of the discussions. Summing up the discussions and the papers Mr. C. C. Renold said that, according to this composite picture, the broad purpose of market research was to provide answers to the questions, what does the customer, in fact, want, and, what is he likely to want in the future? These two questions immediately led to four others: who is the customer, what does he, in fact, buy, what is it that determines or influences his choice, and how much does he buy? The answers to some of these questions can be sought by statistical means; but, especially with consumer goods, other questions lead us into problems of psychology. The answers, too, have to be in two tenses—present and future—and they are determined not only by general movements of economics, trade or social habits, but also by the position of the manufacturer in relation to his competitors. The essential in market research was to select the subject most worth close examination by the techniques available. Mr. A. H. S. Hinchliffe, pointing out that the Manchester Joint Research Council did not itself undertake market research, referred to its information bureau as of possible service to firms unaware of sources of information or market statistics and as possibly able to advise firms on the best sources and consultants for carrying out particular pieces of market research.

Recently Introduced Fungicides

LIME-SULPHUR and Bordeaux mixture, both discovered in the last century, are still very effective and relatively cheap sprays for the control of fungus diseases. It is natural, however, to investigate the possibilities of other substances which might be either more effective or more economical. R. W. Marsh has carried out an extensive series of fruit-spraying trials with various new fungicides (*J. Pom. and Hort. Sci.*, **23**, 3 and 4, Dec. 1947). Phenyl mercury chloride was approximately equal to standard lime sulphur for the control of apple scab; in Grade E oil emulsion, it also gave promising inhibition of sporing of *Monilia fructigena.* Ferric dimethyldithiocarbamate and tetramethylthiuram disulphide are not phytotoxic, but are inferior as fungicides to lime sulphur. Heptadecylglyoxalidine equalled lime sulphur for apple scab control, and did not damage sulphur-sensitive varieties. The last substance, with dichlornaphthoquinone and dithiocarbamate sprays, gave satisfactory control of *Pseudopeziza* leaf-spot of black currants. Spread of brown rot infection of apples was reduced by ferric dimethyldithiocarbamate; but hydroxyquinoline sulphate showed no fungicidal value for apple scab.

Diseases of Mushroom Cultivation

THE Mushroom Growers' Association is a body formed by a particular section of the horticultural industry in order to solve its own pressing problems. Some interesting features relating to mushroom diseases have recently appeared in the Association's Bulletin (Nos. 11 and 12, April and July, 1948). 'Cobweb', caused by overgrowth of beds by *Dactylium* species, is briefly described by Fred C. Atkins. The control of 'bubble', caused by the fungus *Mycogone perniciosa*, is outlined by Edmund B. Lambert. He regards as necessary a complete programme: burning sulphur and fumigating with formalin before the mushroom houses are used, taking water direct from uncontaminated deep wells, attaining a temperature of 120° F. for 48 hr. in the final fermentation of manure and casing soil, and general methods of hygiene. A new leaflet of the Association (No. 3) describes the general characters of *Mycogone* disease. A detailed account of the invasion of mushroom beds by truffles is contributed by A. M. Kligman, and, as control of most mushroom diseases involves rigid methods of hygiene, the necessary measures are considered in detail by R. L. Edwards and C. J. la Touche.

Cosmic Phenomena of the Past

IN a paper, "Further References to Cosmic Phenomena in the Kitāb Al-Muntazam of Ibn Al-Jauzī, and a Few in Tārīkh-E-Rāḥat Afzā (India)", a reprint from *Islamic Culture*, April, 1948, Mohd. Abdur Rahman Khan provides a short account of thirteen fireballs from A.D. 983 to A.D. 1031; three comets from A.D. 974 to A.D. 1056; a comet in A.D. 1741, a detonating fireball in A.D. 1742, and another one in A.D. 1757 and an earthquake at the same time (it is conjectured that the earthquake may have been due to the impact of a large meteorite with the ground), and a slight earthquake in A.D. 1759. This information is additional to that published by the same author in his brochure "Meteoric Showers, Past and Present", some of which was discussed by him in the *Islamic Culture Magazine*, **20**, 4 (1946).

Scottish Conference on Road Research

An all-day conference to discuss road research problems will be held in Glasgow at the Royal Technical College on September 24. The conference is being called, with the collaboration of the Ministry of Transport, by Dr. W. H. Glanville, director of road research of the Department of Scientific and Industrial Research, in association with the Glasgow and District Association of the Institution of Civil Engineers, the Scottish branches of the Institution of Municipal Engineers and the County Surveyors' Society, and the Scottish Accident Prevention Council. The chairman of the conference will be Sir Patrick Dollan. The purpose of the conference is to bring the work of the Road Research Organisation before Scottish engineers and others concerned with roads and road traffic, and to provide an opportunity for discussing which research problems are of particular interest to Scotland. In addition to short papers by the director of road research and senior members of his staff, followed by an open discussion, there will be an exhibition of some aspects of the work of the Organisation. The morning session (deputy chairman: Colonel T. U. Wilson) will be devoted to materials and methods of construction, and the afternoon session (deputy chairman: Mr. G. J. Sherriff) to road safety and traffic flow. Owing to limitations of space, admission will be by ticket, obtainable from the Director of Road Research, Road Research Laboratory, Harmondsworth, West Drayton, Middlesex.

University of London: Appointments

The following appointments in the University of London have recently been announced: Dr. T. Crawford, University professor of pathology in St. George's Hospital Medical School as from October 1. Since 1946 he has been director of pathological services at St. George's Hospital and Medical School; Mr. D. V. Davies, University professor of anatomy in St. Thomas's Hospital Medical School as from October 1. Since 1944 he has been fellow and College lecturer at St. John's College, Cambridge, and in 1945 was Arris and Gale Lecturer at the Royal College of Surgeons; Mr. A. V. Judges, University professor of history of education in King's College as from January 1, 1949. Since 1938 he has held the title of reader in economic history in the London School of Economics and Political Science; Dr. R. T. Williams, University professor of biochemistry in St. Mary's Hospital Medical School as from October 1. Since 1942 he has been senior lecturer in biochemistry and during 1943–44 was in charge of the Department of Biochemistry at the University of Birmingham; Dr. G. L. Clark, University reader in mathematics in Bedford College as from October 1. Since 1947 he has been senior lecturer in mathematics at University College, Cardiff; Mr. T. A. Rodger, University reader in psychology in Birkbeck College as fron October 1. He is at present senior psychologist t the Admiralty, consulting psychologist to the Centra Juvenile Employment Executive and a lecturer i Birkbeck College.

Announcements

Mr. Derek Allan Hough has been appointe general secretary of the Institute of Petroleum wit effect from September 1. Mr. George Sell has bee appointed as editor of the Institute's publication with effect from August 1. Mr. Sell has been publications secretary since March, 1946.

Prof. Walter H. Bucher, of Columbia Universit has been elected president of the American Geophy ical Union to fill the unexpired term of the lat Oscar E. Meinzer. This term will expire on June 3 1950.

Mr. F. A. Secrett has resigned his position a honorary adviser to the Ministry of Agriculture an Fisheries on vegetable production, with effect fro August 1. Mr. Secrett, who is himself a leadin vegetable grower, has held this appointment sinc August, 1942. He will continue his membership the Agricultural Improvement Council.

In recognition of his studies on "Sludged Blood the College of Physicians of Philadelphia has awarde the Alvarenga Prize for this year to Dr. Melvin I Knisely, of the University of Chicago. Th Alvarenga Prize was established by the will Pedro Francisco da Costa Alvarenga, of Lisbo Portugal, an associate fellow of the College, "to b awarded annually by the College of Physicians o each anniversary of the death of the testator, July 1 1883".

The Electronics Division of the U.S. Electr chemical Society is making preparations for symposium on luminescence, to be held during i meeting in Philadelphia, from May 5 until 7, 194 Further information can be obtained from Dr. R. M Burns, Electrochemical Society, 235 West 102 Stree New York 25, New York.

The Nuffield Foundation has provided funds f the establishment of a research fellowship in extracti metallurgy, which will be awarded in consultati with the Institution of Mining and Metallurgy a the Royal School of Mines, London, and will tenable at the Royal School of Mines for a period five years. The funds are sufficient to provide small specialist staff and the necessary equipment addition to adequate remuneration for the fello Further information can be obtained from t Secretary, the Institution of Mining and Metallurg Salisbury House, London, E.C.2.

The Medical Research Council announces that has awarded Rockefeller travelling fellowships medicine to the following, for the academic ye 1948–49: Dr. K. W. Donald, Medical Professor Unit, St. Bartholomew's Hospital, London; D L. P. R. Fourman, Nuffield Department of Clinic Medicine, University of Oxford; Dr. R. H. Girdwoo Department of Medicine, University of Edinburg Dr. A. Isaacs, Department of Medicine, University Sheffield; Mr. A. I. S. Macpherson, Department Surgery, University of Edinburgh; Dr. H. Stoner, Department of Pathology, University Sheffield; Mr. S. F. Taylor, Department of Surger Postgraduate Medical School, London.

Origin of Some Plant Viruses

POTATO paracrinkle virus, discovered by Salaman and Le Pelley[1], has been found in every plant of the variety King Edward that has been examined, but never in other varieties in the field, although it can be transmitted to them by grafting. The inference is that it has no natural means of spreading, and must have been present in the original seedling from which the variety King Edward came.

It is reasonable to infer that the virus was in the seedling because it was a seedling, and either is part and parcel of the clonal variety, or arose during some phase in the life of the seedling not shared by plants propagated vegetatively. The first alternative is ruled out because the virus is not transmitted by seed and behaves in general like other viruses, as Carson *et al.*[2] pointed out in reply to Darlington's suggestion[3] that the virus was a protein constituent of the variety. This leaves the second, which means that the virus arose in the germinating seed or very young seedling, because these are the only phases in the life of a seedling that are not shared by plants propagated vegetatively.

There is evidence for the belief that potato paracrinkle virus is not unique in its origin, and that other plant viruses may have arisen in germinating seed. The biochemical processes during germination are to some extent the reverse of those during the formation of the seed—food reserves built up in the seed are broken down during germination—and if viruses arose during germination there would be a fair chance that they would be destroyed in the seed as it forms. This is precisely what happens, for destruction of those viruses that manage to enter the seed seems universal, even if it is sometimes incomplete. The suggestion that viruses have arisen from occasional syntheses during germination is the simplest explanation of this destruction.

It might be argued that the prevalence of viruses in plants propagated vegetatively is against the suggestion; but this is not so, because one can usually trace a connexion with propagation by seed. Consider the largest two groups of plant viruses: those of stone fruits and of potatoes. Stone fruits are usually (but not invariably) budded on seedling stocks; and, granted a susceptibility of *Prunus* towards viruses, there is (on the present suggestion) the ideal combination for the establishment of new viruses: seedling stocks to produce them and vegetative propagation of varieties to give them a less poor chance of survival. Potatoes are nowadays raised from seed only for the production of new varieties (with the consequence in King Edward already noted). But the raising of new stocks from seed was once common in Europe as well as in the original home of the potato; and it may be significant that, whereas several of the viruses of stone fruits discovered in recent years were not only previously unrecorded but, on local evidence, apparently new, there is no evidence that outside South America the potato viruses, with the exception of paracrinkle virus, are modern.

On following the line of thought in the second half of the previous sentence, it was found that the number of virus diseases first recorded in the literature after the publication of K. M. Smith's "Textbook" in 1937, relative to the number recorded before, is significantly greater for plants usually grown from seed or on seedling stocks than for plants usually propagated only by vegetative means. Details of the test of independence are given in Table 1, which is based on the 156 viruses contained in Wiltshire's[4] list published in 1946, the classification being made on the host plants which give the viruses their common names, and on the dates when the diseases were first recorded, irrespective of whether they were then ascribed to viruses or not. An identical trend is also shown in Table 2, which, to remove any bias that vegetative propagation may give to the detection of virus diseases, is confined to vegetatively propagated plants, and compares plants like peaches, which are usually on seedling stocks, with plants like potatoes, which are usually propagated by simple vegetative means, or, like roses, on stocks raised vegetatively. The records of plant virus diseases are still fragmentary and perhaps unrepresentative, and the host plants after which the viruses are named are sometimes clearly not the original hosts, but the difference between the two sets of records as they now stand is unquestionable. Closer analysis of the effect of time revealed no evidence that the choice of date, 1937, had much to do with this difference.

Table 1. Number of first records of plant virus diseases. Figures in parenthesis are for woody and herbaceous plants respectively

	Plants grown from seed or on seedling stocks	Plants propagated vegetatively	Total
Before 1937	68 (19, 49)	52 (18, 34)	120 (37, 83)
1937 and after	31 (13, 18)	5 (3, 2)	36 (16, 20)
Total	99 (32, 67)	57 (21, 36)	156 (53, 103)

χ^2 for all plants = 10·35; for woody plants = 4·17; for herbaceous plants = 6·80. The 1 per cent and 5 per cent points are 6·64 and 3·84 respectively.

Table 2. Number of first records of virus diseases of plants which are usually propagated vegetatively

	Usually on seedling stocks	Usually vegetative propagation only	Total
Before 1937	12	52	64
1937 and after	11	5	16
Total	23	57	80

χ^2 = 15·62; 1 per cent point = 6·64.

It is not supposed that all diseases recorded since the beginning of 1937 are new, even if, to allow for the inevitable lag in time between the synthesis of a virus and the discovery and record of the disease it causes, one interprets the adjective as covering the last few decades. But it is possible that enough viruses are new enough to influence the date of discovery of the diseases they cause, and thus, if they arise in the seed, to give the records the trend they have. Fortunately, the analysis is one which will automatically improve as records become less fragmentary, and time will allow one to give the possibility a better test.

To conclude, it is suggested that the synthesis in healthy tissue of enough virus to effect further multiplication is a rare event which happens in the protein-rich seed during the intense chemical activity of germination. Rarity is a clear demand of the statistical argument, one successful synthesis followed by successful dispersal being all that is really needed for each virus; and this demand allows a theory of heterogenesis to conform with the substance of the teachings of Pasteur.

Rh Genes Allelomorphic to *D*

Stratton[1], in 1946, described an *Rh* gene allelomorphic to D and d, to which he gave the name D^u. He demonstrated that this allelomorph was inherited in the same way as the other *Rh* genes. During the last two years we have had the opportunity of testing twenty-eight samples of blood of the genotype $D^u d$, nineteen of which were from unrelated English persons.

The tests were exhaustive; they included titrations in saline and in albumin against numerous anti-D sera, and tests by the anti-globulin and by the elution techniques. We consider a sample of blood to be $D^u d$ if it gives some of, but not all, the reactions expected of D when tested by these various methods against the battery of agglutinating and incomplete anti-D sera. The homozygote $D^u D^u$ must be very rare in England, and in the heterozygote $D^u D$ the presence of D^u is masked by that of D.

The reactions of the blood of the nineteen unrelated English persons with twelve anti-D sera are shown in the accompanying table. The twelve sera had each disclosed slight variations in the specificities of their anti-D when they were tested against the nineteen samples of blood. About thirty antisera were used; but the rest appeared to give the same reactions as one or other of the twelve. Conversely, the antisera defined twelve different types of $D^u d$ blood, and presumably if the battery of antisera had been larger, more of the nineteen samples of D^u blood would have been distinguishable.

Examination of the families of ten of the nineteen persons confirmed Stratton's views of the inheritance of D^u; but it went further, and left very little doubt that the fine distinctions between the different types of D^u are also genetically determined, for with one exception the blood of related persons gave identical D^u reactions.

The apparently unlimited number of D^u allelomorphs, together with the very arbitrary way in which the antisera were reacting with them, recalled the work of Dubinin on the many allelomorphs at the scute locus in *Drosophila melanogaster* (as described by Waddington[2]). The problems seemed to have sufficient in common to stimulate us to seek, by rearranging our results, for some such pattern as that into which the scute results apparently fitted. This could be done by cutting up the original most bewildering table first vertically for the sera; then, having decided on their order, redrawing the table and cutting it horizontally for the ordering of the cells. The result was the striking pattern shown in the table. It will be seen that two samples of blood do not fit in at all, but that the remaining seventeen show a horizontal and vertical contiguity of positive reactions uninterrupted by intervening negative ones. There is only one exception to this, in the horizontal direction, about halfway down the table.

It is difficult to decide whether the pattern is a chance one. If it is significant, then the horizontal conjunction of positive signs seems to impose a linear order on the different forms of D^u. It suggests that if the differences between the D^u's are due to mutations, then the mutations may be additive in nature. The vertical conjunction of positive reactions would suggest that an anti-D antibody is built up according to a progressively expanding plan.

It should be mentioned that D^u is much too rare to have been the antigen responsible for the immunization of the twelve mothers whose sera are shown in the table. Probably all these anti-D sera were made in response to the antigen D. It should also be made clear that all twelve antisera would agree in giving positive or negative reactions with at least 99 per cent of blood samples. It is only over the rare D^u bloods that they disagree. The range of an anti-D serum in agglutinating D^u cells is not wholly dependent on the titre of the serum, though there is a positive relationship between range and titre.

The different D^u samples can be graded from those that are agglutinated in saline by most anti-D sera down to those which can only be recognized as having any D^u component by giving a positive anti-globulin test with incomplete anti-D serum. Blood of the latter type will usually have been classified as Cde/cde or cdE/cde.

The C or c, E or e genes with which D^u is usually combined in England strongly suggest that the mutation to D^u, if it is a mutation, occurs to a D gene rather than to a d gene.

The type of blood called $R'r$ (and the same applies to $R''r$) consists of two groups probably differing fundamentally in origin. One group, perhaps the larger, is really antigenically low-grade D^u and is of the genotype CD^ue/cde, which we consider has arisen by mutation in a CDe chromosome. The other group contains the true Cde/cde, which, according to the suggestion of Fisher for which there is some striking support, has arisen as a cross-over between CDe and cde chromosomes.

A detailed account of the family and serological investigations will be reported elsewhere.

We are indebted to many *Rh* workers for sending us samples of D^u blood and anti-*D* sera. Particularly we would like to mention Dr. F. Stratton, Dr. F. S. Stewart, Mr. I. Dunsford and Dr. A. E. Mourant.

[1] Stratton, F., *Nature*, 158, 25 (1946).

[2] Waddington, C. H., "Introduction to Modern Genetics" (London, George Allen and Unwin, 1939).

IN 1945 a cell sample was discovered reacting with only a proportion of anti-*D* sera. This suggested a new allele of *D* which was called D^u [1]. 209 *Rh* antisera stored at − 20° C. for periods up to several years have been tested with D^u cells of types CD^ue and cD^uE, selecting the appropriate cell to avoid the effect of anti-*C* and anti-*E* agglutination in sera containing more than one antibody. 102 of these sera contained anti-*Rh* agglutinins, and 37 of these (36 per cent) agglutinated D^u cells, some weakly, some very strongly. These sera all contained anti-D + D^u agglutinins; anti-D^u by itself has not been detected. 71 of these agglutinating sera were free from anti-*C* and anti-*E* agglutinins, and 27 of these (38 per cent) agglutinated D^u cells. These 27 comprised 13 per cent of all the sera tested. The remaining 107 sera contained incomplete antibodies, many of which were weak; and 36 of them (34 per cent) gave positive Coombs tests with D^u cells. Eight of these gave positive albumin tests also, and five sera gave positive albumin tests only. In addition, strong incomplete *Rh* antibodies from ten cases of incompatible transfusion all gave positive Coombs tests with D^u cells, as did ten agglutinating sera which gave negative agglutination with D^u cells.

D^u cells vary in the strength of their reactions and in the number of agglutinating sera with which they react; and some are negative with all agglutinating sera, so that R_1 (CD^ue) and R_2 (cD^uE) may only be distinguishable from R' (*Cde*) and R'' (*cdE*) by the positive Coombs tests which they give with certain incomplete anti-*D* sera, especially those from cases of incompatible transfusion. A series of strongly positive albumin tests, on the other hand, suggests that the cell is an ordinary *Rh* positive one and does not contain D^u, since D^u only rarely gives positive albumin tests with incomplete anti-*D* sera.

The best method of investigation has proved to be the comparison of the reactions of various cells with a large number of sera, and we have examined fifty cell samples mostly thought to be R' (*Cde*) and R'' (*cdE*) in the first instance. They were tested with forty-nine agglutinating sera, and with fourteen incomplete anti-*D* sera, employing the Coombs test and albumin test. Detailed results will be published elsewhere; but a selection is given in the accompanying table. D^u cells vary in strength from very weak reactors to those which are scarcely distinguishable from ordinary *D* positive cells.

It will be observed that the D^u antigen in cell No. 39 can only be detected by the Coombs test. This cell gave negative albumin tests even with three specially selected incomplete anti-*D* sera which gave strong albumin tests with more strongly reacting D^u cells, such as cell No. 13.

Several samples of maternal blood of group R' (*Cde*) or R'' (*cdE*) containing *Rh* antibodies were examined; but no evidence of the presence of D^u was found. For this reason, and since van Loghem[3] found that D^u could be antigenic to an *Rh* negative person, D^u is considered to be *Rh* positive and should be excluded when selecting *Rh* negative blood donors. The most practical way to do this as a routine is by the use of anti-*C* and anti-*E* sera in addition to the use of several anti-*D* sera. This will exclude the vast majority of D^u positive cells. D^u also has a practical importance in that R_1 (CD^ue) and R_2 (cD^uE) cells are readily mistaken for R' (*Cde*) and R'' (*cdE*); and if such cells are used for testing purposes, one may falsely be led to suppose that agglutinating or blocking sera contain anti-*C* or anti-*E* antibodies in addition to anti-*D*.

Inheritance of D^u has been demonstrated, but we are at present making more family studies to substantiate the hypothesis that D^u is a term covering a series of alleles or modifications of the *D* antigen at the *D*—*d* locus.

Since sera which agglutinate D^u cells do so to a lower titre than the same sera agglutinate cells containing the ordinary *D* antigen, and since absorption of sera with either *D* or D^u cells does not effect any separation of the antibodies anti-*D* and anti-D^u, it might be thought that the phenomena were quantitative and dependent on a varying amount of the *D* antigen in the cell. However, this cannot be the case since the sera which agglutinate the greatest number of D^u cells are not always those with the highest titres when tested against cells containing the *D* antigen, and since cases have been found where, of a pair of sera, only one agglutinated one sample of D^u blood while the other agglutinated the second.

	Agglutinins								Incomplete antibodies						
Type of serum	Anti-*C*	Anti-*D*						Anti-*E*	Coombs test Anti-*D*			Albumin test Anti-*D*			
Serum No.	19	35	37	40	20	28	16	43	11	7	9	11	7	9	
Cell No.															Conclusion
1	−	64	64	4	16	16	4	++++	++++	++++	++++	+++	+++	+++	R_2 (*cDE*)
13	−	8	8	1	1	−	−	++++	++++	++++	+++	−	−	−	R_2 (cD^uE). Strong reactor
23	−	2	1	1	−	−	−	++++	++++	+	++++	−	−	−	R_2 (cD^uE). Medium reactor
15	++++	W	−	W	−	−	−	−	++++	−	++++	−	−	−	R_1 (CD^ue). Weak reactor
39	−	−	−	−	−	−	−	++++	+++	−	++	−	−	−	R_2 (cD^uE). Weak reactor
14	++++	−	−	−	−	−	−	−	−	−	−	−	−	−	R' (*Cde*)
8	−	−	−	−	−	−	−	++++	−	−	−	−	−	−	R'' (*cdE*)

Number of +'s indicates strength of reaction. W = weak. − = negative. Figures indicate the titre of strongly positive reactions.

Nevertheless, it was found that the sera with the highest titres for D cells were frequently good agglutinators of D^u, so that it does appear that a serum containing a strong anti-D agglutinin is more likely to react strongly with D^u.

When antigens like D and D^u are closely related, the possibility of a cross-reaction of each antigen with antibodies produced against the other is high. This shows that while a quantitative element is involved, there are also distinct qualitative differences between D and D^u.

Viropexis, the Mechanism of Influenza Virus Infection

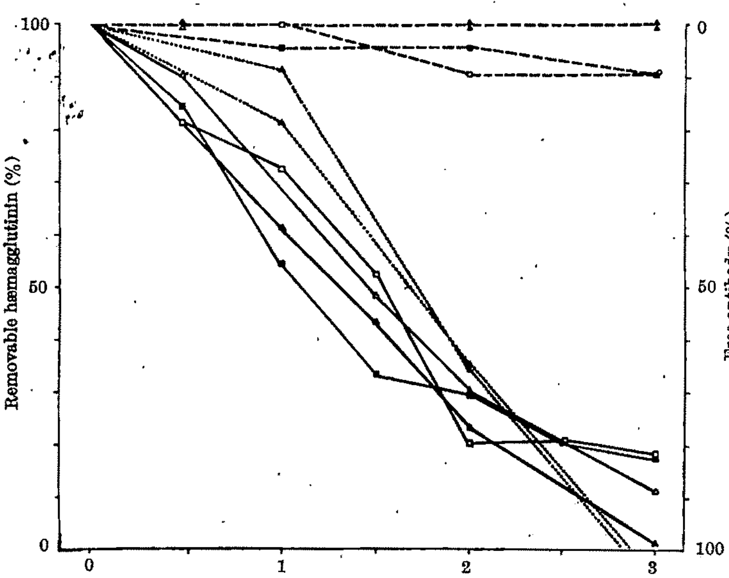
CELLULAR receptors capable of reacting with influenza viruses (such as those on erythrocytes, and the cells lining the respiratory tract of the mouse or the allantoic cavity of the chick embryo), when treated with appropriate amounts of periodate, still adsorb virus; but spontaneous elution does not occur nor can artificial liberation be induced by the 'receptor-destroying enzyme' of *V. choleræ*, an agent known to remove bound virus from normal receptors. On the basis of a detailed study, it was concluded that the substrate for the receptor-destroying enzymes of the virus or vibrio is altered by periodate ions without significant change in the adsorptive capacity of the receptor area, so that the contact of such treated cells with virus results in an irreversible receptor-virus combination[1]. In further experiments it was shown by four independent methods, both in mice and developing chick embryos, that despite 'modification' by periodate, infection takes place through such receptors; obviously, these conditions do not allow of any enzymatic action of the virus on the receptor substance[2]. The uptake of the particle adsorbed to the exoplasm of the future host cell is believed to be a process essentially similar to the phenomenon of colloidopexis.

Since the objection may be made that this mechanism is at work only on receptors previously modified by periodate, further experiments using heat-killed virus and normal receptors were carried out.

The allantoic fluid of living eggs was removed, and replaced by physiological sodium chloride solution containing a standard amount of active or heat-killed (30 min. 56° C.) Lee virus. At intervals ranging from 0 to 180 minutes, a potent receptor-destroying enzyme preparation was inoculated to remove virus still present at the surface of the cells. The fluids were harvested at the end of the fourth hour, and titrated for their agglutinin content. The experiment was repeated with eggs the allantoic lining of which had been killed by formaldehyde. The percentage of removable virus at different intervals is given in the accompanying graph.

In a second series of experiments, use was made of the fact that specific antibody combines with virus only outside the cell. The second inoculum in this case contained antiserum sufficient to neutralize the amount of virus—active or heat-killed—given in the first inoculum, and the drop in anti-hæmagglutinin titre served as a measure of virus present at the surface of the cells or in the fluid. The experiments were performed on normal, formolized and periodate-treated eggs.

From the graph it is clearly seen that both active and heat-killed viruses disappear from allantoic cavities with living cellular lining, irrespective of whether the receptors are normal or modified by periodate. In formolized cavities, that is, cavities lined with dead cells, all the virus is recovered. Obviously, the penetration by the virus of the cell membrane does not depend on the viability or enzymic activity of the infective particle, but only on the functional integrity of the host cell.



Percentage of recoverable virus (active and heat-killed) in allantoic cavities lined with living or dead cells

—— Untreated eggs, living; .... periodate treated eggs, living; - - - formolized eggs, dead.

□ active virus
■ heat-killed virus } receptor-destroying enzyme liberation technique

△ active virus
▲ heat-killed virus } antibody neutralization technique

Each point represents the average from 36 eggs

The 'enzyme-substrate combination hypothesis', recently reiterated by Hirst[3] on no better evidence than originally proposed[4], cannot be accepted in the light of the above findings. All Hirst's experiments to elucidate the mechanism of infection were performed on non-living systems or on non-host cells, the strongest proof in favour of his assumptions being the momentary lack of contradictory evidence.

The above results, taken together with the fact of influenza infection through periodate-modified receptors, suggest a different mechanism. Specific adsorptive combination between the cellular 'receptor area' and the viral 'combining area' ('B-spots' in the terminology of Burnet[5]) is followed by the ingestion of the infective particle. This phenomenon strongly recalls the uptake by cells of colloidal dyes, and may therefore be termed 'viropexis'. Enzymic activity and destruction of receptors—formerly postulated as prerequisites for the penetration of the virus into the interior of the host cell—do not seem to be essential, though possibly the invariable occurrence in natural infections with enzyme-possessing viruses.

Polyploidy in Bacteria?

IN the course of experiments on the bactericidal action of X-rays on the *R* and *S* phases of *Escherichia coli*, it was found that the survival-rate in three stocks (76, 111, *Ida*), irradiated twenty-four hours after seeding, was different[1]; one of them (stock *Ida*) was more resistant to the radiation as compared with the other two stocks. No significant differences were found between *S* and *R* phases of the same strains. According to the hit-theory of biological effects of radiation the survival-rate is a measure of the target volume, which has been assumed to represent the bacterial 'nucleus'[2,3]. If in the case of bacteria the so-called nucleoplasmic ratio of plants and animals holds true, and if, on the other side, the target volume obtained from X-ray experiments really represents the size of the bacterial 'nucleus', one would expect the size of the bacterial cells to be correlated to the target volumes. A biometric analysis of twenty-four hours old bacteria, carried on the projected images of photomicrographs of bacteria stained with Henrici's Congo Red method[4], has shown that *E. coli* with a larger target volume are larger than the ones with smaller target volume. The variability curves obtained for the three stocks were almost normal, and the differences found between their means were statistically significant. It is suggested that such correlation might indicate the presence of polyploidy among different stocks of the same bacterial species, as it has previously been found in other organisms. A detailed description of such experiments will be published elsewhere.

Occurrence of *Talorchestia brito* on the Coast of Northumberland

Talorchestia brito was originally described by Stebbing in 1891 from specimens collected on the north Devon coast[1]. No further records of its occurrence on the coasts of Britain can be found, though, according to Chevreux and Fage[2], it has been recorded from a number of scattered points on the Continent from the eastern English Channel to the western Mediterranean. It has now been found about three hundred miles north of any previous record near Blyth, Northumberland, being moderately common between high-water neap and high-water spring tides in the coarse sand to the south of the town. The species appears to be restricted to this stretch of about two miles, and has not been found on any other sandy beach in Northumberland or north Durham.

On July 6, 1948, the population of *T. brito* consisted of adults, including females carrying eggs, and recently hatched young. *Talitrus saltator* was also present, but was much less abundant.

Laminaria ochroleuca De La Pylaie Growing on the Coast of Britain

ON April 10, 1946, a *Laminaria* plant, trawled in Plymouth Sound and brought into the Plymouth Laboratory by Miss M. F. Sutton, Department of Biology, Chelsea Polytechnic, was identified by me as *Laminaria ochroleuca* De La Pylaie, a species of *Laminaria* that had not previously been recorded from the coasts of Britain. As trawling over the same ground on subsequent days failed to procure further plants of this species, the record was not published. A recent survey, however, has shown that this species occurs quite frequently in the more sheltered parts of Plymouth Sound. It is found on rocky ground from just below, down to eight metres below, low water spring tides, growing usually with *L. cloustoni* Edmondst. or *Saccorhiza bulbosa* De La Pylaie.

L. ochroleuca can be distinguished at any time of the year from *L. digitata* (L.) Lamour. and *L. cloustoni* Edmondst. by the colour of the base of the frond, which is always whitish-yellow, and by the smooth stipe which contains mucilage canals in the outer layers. During the spring and early summer, when frond growth is very rapid, the whole frond is a pale yellowish-brown; but during late summer, autumn and early winter, when growth is slower, the distal part of the frond becomes darker, the distinguishing whitish-yellow colour being noticeable only at the base.

L. ochroleuca (= *L. lejolisii* Sauvageau, *L. pallida* (Grev.) J. Ag. var. *iberica* Hamel, *L. iberica* (Hamel) Lami) is recorded from the western Mediterranean and from the north-eastern Atlantic. On the French side of the Channel it is recorded at localities from Finistère to Cotentin. There are also records of its occurrence in the Channel Islands.

Dr. Robert Lami, of the Muséum d'Histoire Naturelle, Paris, who has worked on the distribution of this species on the French coast[1], informed me in 1945 that he thought this species might have 'crossed the Channel' and invaded the south coasts of England and Ireland because of its abundance on the coast of Brittany. Plants up to five years old are now present in Plymouth Sound; but it is not known how long this species has been there. It was almost certainly not present up to 1900, otherwise it would have been recognized and recorded by Prof. T. Johnson[2], who made an intensive study of the marine algæ of Plymouth Sound during 1885–1900. I would, therefore, be grateful for any records of the occurrence of this species on the coasts of Britain, so that its distribution or its rate of migration can be followed.

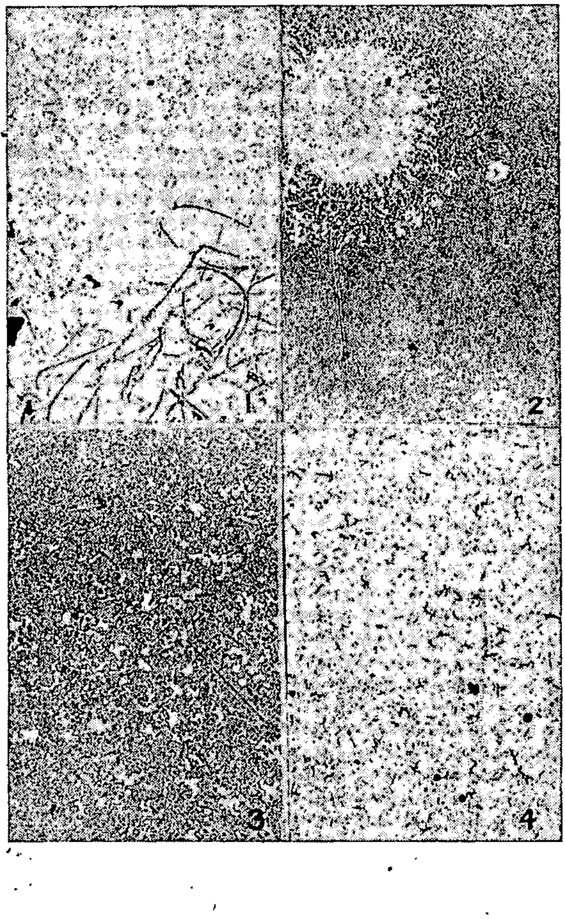
Insecticidal Power and Microscopical Structure of Residual Films of Benzene Hexachloride

In some recent experiments with samples of the γ-isomer of benzene hexachloride (1,2,3,4,5,6-hexachlorocyclohexane), in which adult beetles of *Dermestes maculatus* Deg. were tested on residual films prepared on glass plates by a recently devised method[1], it was found that in films formed from chloroform solutions, a certain sample of 'technical' grade material (I) was more insecticidal than the corresponding 'refined' sample (II) and 'refined' (III) and 'technical' (IV) samples of different manufacture. These unexpected observations were the reverse of those obtained by other investigators testing the same samples by different methods[2]. Furthermore, when residual films of the insecticides in a light, refined paraffin spray oil were prepared and tested in this laboratory, samples (II) and (III) were at least as toxic as (I).



A microscopical examination of the chloroform films showed that those prepared from sample (I) were different from the others. After a few hours films of (II), (III) and (IV) had crystallized (Figs. 2, 3 and 4), whereas those of (I), prepared at the same time, under the same conditions, had not: the film was present in the form of discrete globules (Fig. 1, upper). These globules crystallized after insects had walked on them (Fig. 1, lower). Unfortunately, because of the high volatility of benzene hexachloride and the resulting short life of the films, it has not so far been possible to obtain crystals in chloroform films of (I) in any other way. Examination of residual films resulting from light paraffin solutions, where crystallization was considerably retarded in every case, showed that films of samples (I) and (IV) were most retarded.

It is of interest to compare these observations with those of Parkin and Green[3], who found, however, that crystallization of globule films of D.D.T. resulted in increased toxicity.

At this juncture no full explanation of my observations can be offered. It seems reasonable to suggest, however, that the unexpectedly high toxicity of sample (I) is not entirely due to an impurity, but may be associated with traces of chloroform retained by the film. The matter is being further investigated.

Thanks are due to Dr. R. A. E. Galley for supplying information, and to the Council of this Research Association for permission to publish.

Synthesis of *l*-Sparteine

In view of the synthesis of *dl*-sparteine reported by Leonard and Beylen[1], we wish to place on record that some time ago we effected the reduction of *l*-oxysparteine to *l*-sparteine by treatment with lithium–aluminium hydride. Full details of this work will be published elsewhere in due course.

Since the total synthesis of *dl*-oxysparteine[2], the resolution of *dl*-lupanine[3], the transformation of this and its *d*-component into *dl*- and *l*-sparteine respectively[3,4] and the oxidation of *dl*-sparteine to *dl*-oxysparteine[4] have been accomplished in these laboratories, the structure of *l*-sparteine is now completely established.

Testicular Hypoplasia and Epididymal Cysts in the Syrian Hamster

We have observed certain definite changes in the testes of some inbred hamsters. These changes are characterized by a striking testicular hypoplasia, mostly bilateral. Such testes, represented sometimes by structures which are almost invisible to the naked eye, appeared very pale, with an apparent lack of normal vascularization. Their individual weight was only 2–306 mgm., as compared with a testicular weight of 0·900–1·400 gm. in the normal hamster. However, we have observed fertile animals the individual testes of which weighed only 0·580 gm. The hamsters with bilateral hypoplasia were, without exception, sterile. On the other hand, the animals with unilateral hypoplasia proved to be fertile. No relationship was found between the hypoplasia and the growth-rate or mature weight of the animals. Although we have also observed hypoplasia of the ovaries and sterility in some females, our data in this respect are inconclusive.

In the epididymi of some inbred and outbred hamsters we have encountered single and multiple cysts, histologically connected with the epididymis itself. Such cysts, of a yellow colour and of a sterile content, varied greatly in size: they varied from the size of a very small pearl to that of a normal hamster testis. In some animals these cysts were found in both epididymi, although most of them were unilateral. Most of the cysts were found in the tail, although a few of them occurred in the head of the epididymis. Most of them contained mainly spermatozoa.

Through the study of the reproductive capacity of hamsters with normal testes but with epididymal cysts, unilateral or bilateral, in some cases making use of surgical ligatures, we observed that the cysts impaired the fertility of the animals only when they were of considerable size, especially when such cysts were located near the beginning of the ductus deferens. This shows that these cysts can produce sterility only by mechanical blocking of the normal passage of the spermatozoa through the epididymis.

In a few cases we have also observed another kind of cyst, the contents of which are devoid of spermatozoa. They are small, yellow formations, usually flattened, round or ovoidal. These cysts are found either free, in the neighbourhood of, or loosely connected to, the tail of the epididymis.

The testicular hypoplasia was observed only in a group of inbred hamsters. They were of different age, 92–240 days, and under different dietary regimes. The epididymal cysts, found in both inbred and outbred animals, were observed mostly in very mature hamsters, 220–240 days of age. The cause of the hypoplasia seems to be of a hereditary nature, similar to that described by Lagerlöf[1,2] and Eriksson[3] in cattle. A complete report with a histological study is being prepared.

Isophosphorylase

Both pure potato phosphorylase[1] and crystalline muscle phosphorylase[2] produce from glucose-1-phosphate a non-branched polysaccharide containing only α-1,4-glucosidic links and resembling amylose. By the action of extracts of yeast[3], of heart, brain or liver[4], branched polysaccharides are obtained containing up to 10 per cent of α-1,6-glucosidic linkages and resembling glycogen. In 1942, Meyer and Bernfeld[5] reported the presence of an enzyme in yeast which brings about the phosphorolysis of the terminal α-1,6-glucosidic links of residual dextrin (the final degradation product of amylopectin by β-amylase). A purified potato phosphorylase was not able to effect this reaction. It was therefore concluded[5] that there are two different phosphorylases, one of which effects the fission or synthesis of α-1,4-glucosidic links, the other the α-1,6-glucosidic links involved in branching. Cori[6] has found an enzyme in liver extract and also in heart extract which he calls the 'branching factor', and which is able to produce glycogen by simultaneous action with the crystalline muscle phosphorylase. Haworth, Peat and Bourne[7] have described a thermolabile factor which they term the '*Q* enzyme' and to which they attribute the property of synthesizing the α-1,6-glucosidic links in amylopectin. Their '*Q* enzyme' has, in addition, an amylatic action.

We have now succeeded in finding also in potato extract an enzyme which, in the presence of inorganic phosphate, renders residual dextrin accessible to β-amylase attack (see Table 1).

Table 1. Simultaneous action of potato extract and β-amylase on residual dextrin

Addition of potato extract	Degradation by β-amylase	
	Phosphate present	Phosphate absent
Without	0 per cent	0 per cent
With	25 ,,	5 ,,

We have been able to show that, in the presence of phosphate, this same enzyme converts amylose to amylopectin and even to glycogen by simultaneous action with potato phosphorylase (see Table 2). No conversion takes place in the absence of inorganic phosphate.

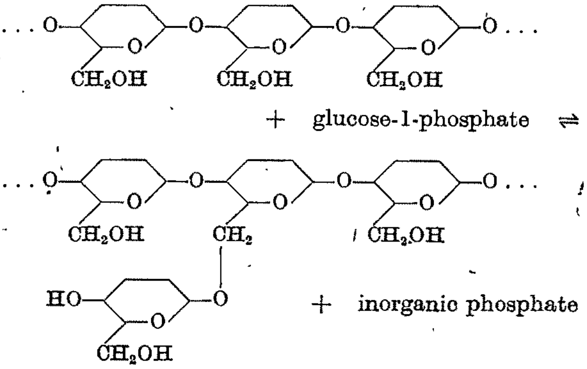
Table 2. Simultaneous action of potato extract and potato phosphorylase on corn amylose

Time in hours	Phosphate present 1·35 P/amylose*		Phosphate absent less than 0·01 P/amylose*	
	Iodine coloration	Conversion limit by β-amylase[8]	Iodine coloration	Conversion limit by β-amylase[8]
0	blue		blue	
24	violet		blue	
72	purple		blue	
144	purple	65%	blue	100%

* Mols of phosphate per glucose equivalent of amylose.

The results given in Tables 1 and 2 show that potato extract contains an enzyme capable of catalysing the phosphorolysis of α-1,6-glucosidic links and equally of their synthesis. We propose to call this enzyme 'isophosphorylase'.

Meyer and Bernfeld[5] have shown that potato phosphorylase only brings about the fission of α-1,4-glucosidic links which are proximate to terminal non-reducing groups. This has been confirmed quite recently by Katz, Hassid and Doudoroff[9]. We have found that isophosphorylase does not attack linkages in the interior of the molecule, and in this respect behaves like phosphorylase, as the viscosity of a starch paste is not reduced in the presence of isophosphorylase. The reversible catalytic effect of isophosphorylase may therefore be schematically represented as follows:



Furthermore, the behaviour of isophosphorylase with regard to the viscosity of starch paste proves the absence of any α-amylatic action in our preparations, which are thus distinct from the '*Q* enzyme' of Peat, Bourne and Barker[7].

We are indebted to Prof. K. H. Meyer for his interest in this investigation.

Astaxanthin in Insects and Other Terrestrial Arthropods

In a very interesting note on the carotenoids of the locust integument, Goodwin and Srisukh[1] point out the presence of astaxanthin, besides other carotenoids, in *Locusta migratoria* and in *Schistocerca gregaria*. "The demonstration of astaxanthin in locust," they say, "is particularly interesting because, apart from its detection in the retina and eye colourings of birds, this is the first time it has been reported in land animals."

This statement is not quite exact. In 1939 I found this pigment in a mite of the genus *Trombidium*[2]. The pigment is completely extracted by acetone from the mite's body, transferred to petroleum ether and obtained, through evaporation of the solvent, as a red oily residuum (from 3 gm. of mites, 2 gm. of this oil). After saponification, the pigment is taken up again in benzene and after purification by chromatography gives crystals which are intensely violet to red violet under the microscope (2 mgm. of crystals). They give all the reactions characteristic for carotenoids and a peculiar absorption spectrum (a single band at 515 mμ in carbon disulphide and at 500 mμ in pyridine). This result and the chromatographic behaviour and solubility indicate undoubtedly astaxanthin. It is quite probable that this pigment is not infrequent in insects and in other arthropods.

Last year I found a pigment of a similar kind in the potato beetle (*Leptinotarsa decemlineata*). The benzene fraction of the carotenoid pigment gives, with benzene at 70–80°, an orange-yellow zone that splits up in two zones: an epiphasic one, rose-yellow, consisting of β-carotene; an epiphasic one, that is progressing on the column very slowly, eluted with benzene at 70–80° which shows a rose-yellow colour, rose in carbon disulphide, with a spectrum showing one large band with maximum near 497 mμ[3,4]. This pigment looks like the carotenoid pigment that I extracted and crystallized from the fat of a *Phœnicopterus roseus*, the carmin-rose feathers of which perhaps owe their colour to this very pigment. This pigment, which I called 'phœnicoxanthin'[2], shows one adsorption band near 490 mμ in pyridine and differs from astacene both in the position of the adsorption band and in the different solubility and different colour in various solvents.

A full series of investigations is being planned in order to study the metabolism of carotenoid pigments in *Leptinotarsa* fed on various Solanaceæ.

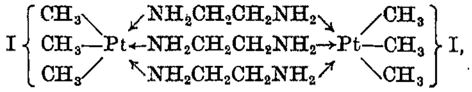
The Trimethylplatinic Group

Pope and Peachey[1] prepared diamminotrimethyl platinic iodide, $(CH_3)_3PtI(NH_3)_2$, readily soluble in alcohol, but sparingly soluble in water. We now find that pyridine added to trimethylplatinic iodide in benzene gives after concentration dipyridinotrimethylplatinic iodide, $(CH_3)_3PtI(C_5H_5N)_2$, m.p. 168°, without previous decomposition, and that similarly from all proportions of dipyridyl and trimethylplatinic iodide, dipyridyltrimethylplatinic iodide, $(CH_3)_3PtI$, dipy, is obtained, insoluble in water, but soluble in chloroform and acetone, m.p. 268–273°. It is apparently unchanged by boiling with dilute acetic acid, hydrochloric acid, ammonia or twice normal sodium hydroxide. It is, however, decomposed by ethylene diamine with formation of sesquiethylenediaminetrimethylplatinic iodide, $2(CH_3)_3PtI.3en$, which may be recrystallized from water. The latter compound can also be prepared from excess of ethylene diamine and trimethylplatinic iodide in benzene. Its structure is probably:



$$\mathrm{I}\left\{\begin{array}{l}\mathrm{CH_3}\searrow \quad \swarrow\mathrm{NH_2CH_2CH_2NH_2}\searrow \quad \nearrow\mathrm{CH_3}\\ \mathrm{CH_3{-}Pt \leftarrow NH_2CH_2CH_2NH_2 \rightarrow Pt{-}CH_3}\\ \mathrm{CH_3}\nearrow \quad \nwarrow\mathrm{NH_2CH_2CH_2NH_2}\nearrow \quad \searrow\mathrm{CH_3}\end{array}\right\}\mathrm{I},$$

recalling that of iron enneacarbonyl[2]. On refluxing ethylenediamine with excess of trimethylplatinic iodide in benzene, trimethylplatinicmonoethylenediamine iodide, m.p. 204° with decomposition, is obtained. Both ethylenediamine compounds are soluble in water. All four compounds, as also the stable association of trimethylplatinic acetylacetone into double molecules[3,4], are examples of the familiar stability of 6-covalent compounds of quadrivalent platinum.

Less easily classified is the compound obtained from trimethylplatinic acetylacetone or from dipyridyltrimethylplatinic iodide by treatment in benzene with dipyridyl or thallous acetylacetone respectively (m.p. 142–43°, separate and mixed). This compound gives good nitrogen figures for dipyridyltrimethylplatinic acetyl acetone. From a solution of the last-named compound in dilute aqueous acetic acid, dipyridyltrimethylplatinic iodide is precipitated by potassium iodide. The investigation of these and similar compounds is being continued.

The solubilities in water of trimethylplatinic halides, oxide and nitrate[1], closely resemble those of the corresponding silver salts. To use Grimm's expression[5], the trimethylplatinic group is a pseudo-atom of such a nature that other atoms or groups brought into its neighbourhood are frequently subjected to a field similar to that existing in the neighbourhood of a silver atom. We have been unable to find an explanation of this effect.

Glide Bands in Silver Chloride

As already reported[1], polycrystalline sheets of silver chloride show both sharp and diffuse bands of birefringence after plastic deformation. In addition to this effect, plastic deformation causes fine lines to appear on the surfaces of the sheets; these are similar to the glide lines seen on metallic surfaces which have been polished and then deformed. Examination under the microscope with oblique illumination makes it clear that they are steps. This conclusion is confirmed by using the 'shadow-casting' technique developed in connexion with electron microscopy. Measurements made with an optical microscope of the widths of the shadows cast by the steps show that the heights of the most prominent steps are of the order of 4000 A. It would appear, therefore, that the principal, and perhaps the only, mechanism of plastic deformation in silver chloride is glide. In this respect silver chloride differs from sodium chloride, which at room temperature becomes deformed mainly or entirely by kinking[2,3].

Some grains contain a system of birefringent bands with a series of surface steps running parallel to them. However, bands are frequently seen that are not accompanied by a parallel series of steps and, conversely, most surface lines do not run parallel to a system of bands. The connexion between the bands and the steps has been made clear by the following experiments. Rectangular bars of length 25 mm. and approximately square cross-section (1 mm. × 1 mm.) were recrystallized and large portions were found to consist of chains of single crystals joined up end to end. Plastic extension of these specimens produced the phenomena already observed in the sheets; but the true direction of a given set of glide planes could now be determined by measuring the direction of their traces on two non-parallel surfaces. In this way it was established that, whenever a set of glide planes is observed edgewise, sharp birefringent laminations become visible between crossed nicols. As the direction of observation becomes inclined to the glide plane, the boundaries of the glide packets become less sharp; the stress patterns in different glide packets overlap and their details are obscured.

The explanation of the characteristic appearance of deformed polycrystalline sheets may therefore be summarized as follows:

(*a*) Most of the grains in a severely deformed sheet contain two or more sets of operative glide planes.

(*b*) A set of glide planes produces steps on the surface, provided the direction of glide is not parallel to the line of intersection of glide plane and surface.

(*c*) The lamellæ which lie perpendicular to the surface give sharp birefringent bands; other lamellæ give diffuse bands or irregular patches of birefringence.

(*d*) Occasionally a single grain contains two sets of operative glide planes lying perpendicular to the surface. In such a case intersecting systems of birefringent bands are observed (Fig. 2 in ref. 1).

(*e*) In flat strips, either bent or extended by uniaxial tension, the stress system is such that the glide direction in planes lying perpendicular to the surface will tend to be parallel to the surface (at 45°, to the direction of the tension). This explains the frequent occurrence of birefringent band systems not accompanied by surface steps.

Experiments to determine the glide system in silver chloride had an interesting result. The orientations of a number of single grains in both sheets and bars were found by taking X-ray back-reflexion Laue photographs. The crystallographic plane of low indices lying nearest to the observed glide plane was not always the same. Out of six systems of glide bands observed in the bars, four were closest to {111} planes, but in the other two systems the closest plane was a {221}. Out of the eight sets of bands observed in plastically deformed sheets, six were closest to {111} planes and two closest to {112} planes. But in none of these cases was there exact coincidence between crystallographic plane and glide plane; the angle between them had an average value of 4·2°, and in one case was as much as 8·1°. This is far greater than the error of the determination (estimated at ± 1·5°). In spite of its non-crystallographic orientation, however, the glide plane was, in all cases except one, found to contain a [110] direction. This behaviour is reminiscent of that discovered in iron by Taylor and Elam[4] in which only the glide direction, [111], is fixed crystallographically, the glide plane being dependent on the stress distribution.

In the tensile experiments on bars of silver chloride, the [110] direction lying in the glide plane was always that one of the six equivalent [110] directions which lay most nearly at 45° to the direction of the tension, or, if there were two glide systems in the same grain, the two [110] directions nearest to the 45° position were selected. Moreover, the glide plane was never more than 9° away from the plane of maximum resolved shear stress containing this favourable [110] direction. This evidence strongly suggests that at room temperature silver chloride becomes deformed by 'pencil glide'[4] in the [110] direction. In iron crystals, pencil glide is connected with the fact that at room temperature the critical stress for glide is the same on three different crystallographic planes, all containing a common glide direction. It seems that this process has not been observed until now in any other crystals. A pencil glide can easily spread from one grain to its neighbour, and this explains the frequent occurrence in the silver chloride sheets of slip lines continuing across grain boundaries.

In single crystals of silver chloride extended by simple tension, Stepanow[5] found glide on planes within 5° of {110} in a [110] direction. This result is in agreement with the conclusions reached above, for in Stepanow's experiments the crystals happened to be prepared with a {100} plane perpendicular to the axis of tension and, under these special conditions, the glide elements to be expected on the present theory are just those that he reported.

Thickness and Height of the Sodium Layer Responsible for the Strong Yellow Line in Twilight

In a communication in *Nature*[1] in 1940 I gave a short account of results of investigations on "The Atmospheric Layer from which the Yellow Line in Twilight Originates". From a series of spectrograms from the zenith followed by one from near the horizon, the effective screening height (H_s) of the atmosphere and the upper limit (H_u) of the effective sodium layer were determined. Since then, the results of extensive series of observations from Oslo and from the auroral observatory at Trömso have been published[2,3].

All observations give nearly the same value of (H_s) and (H_u). The mean values were found to be $H_s = 49$ km. and $H_u = 110$ km. The results lead to the conclusion that ultra-violet radiation in the region near 2,500 A., strongly absorbed by ozone, is essential for the excitation of the sodium line in twilight.

Photometric measurements of the intensity of the line for successive twilight spectrograms show that as a rule the intensity keeps nearly constant until it suddenly falls to a lower order of magnitude in the course of a short time (Δt), when the shadow produced by the screening layer leaves the upper limit (H_u). If the sodium layer had been evenly effective throughout the whole interval ($H_u - H_s$), the intensity should have decreased gradually during the time it takes for the effective shadow limit to pass from H_s to H_u.

It is therefore legitimate to conclude that the effective sodium layer is restricted to a thin layer, and that the sudden drop of intensity of the D-line begins when the shadow reaches the lower limit of this layer.

Using the zenith observations, the thickness (ΔX) of the layer is given by the formula:

$$\Delta X = (R + H_s) \cos \varphi \frac{\sin h}{\cos^3 h} \cos \delta \sin t \, \Delta t,$$

where R is the radius of the earth, and h, δ and t the height, declination and hour angle of the sun. The value of ΔX has been calculated for twenty series of observations taken at Oslo between October 1942 and April 1943.

The values found for ΔX vary between 8·4 km. and 27·6 km., with an average of 16·2 km. The fluctuations are greater than the possible errors and are, no doubt, to a certain extent real. The values indicate a minimum in December and January and maxima in the autumn and spring. A regular annual variation of H_u and H_s has not yet been found. On an average the sodium layer effective in producing the strong D-line in twilight seems to cover a height interval from about 90 to 110 km.

Treatment of Paper with Silicon Esters

During an investigation of the possibility of cross-linking nitrocellulose molecules in solution with silicon esters[1,2], some experiments were also made with cellulose itself in the form of filter paper or unsized kraft paper.

The silicon esters used were tetramethyl, tetraethyl and a polymer ethyl ester (boiling range 210–360°). In a first series of experiments, ordinary filter papers (11 cm. diameter) were exposed to vapours of silicon esters at high temperatures and afterwards placed in a funnel, which was then filled with water. Treatment with ethyl ester for 16 hr. at 120° produced a filter paper which was completely impermeable to water for 11 hours. In a second series of measurements the treatment was made with liquid esters instead. Papers which had been immersed in polymer ethyl ester for 4–66 hr. showed a regularly increasing impermeability against water, improving from 1 to 50 hours. Unsized kraft paper gave similar results, whereas experiments with sized paper of different kinds were unsuccessful.

The wet strength of treated unsized kraft paper was three to seven times larger than that of untreated paper. In order to get the treated papers completely wetted, it was necessary to keep them immersed in water for about one week.

It is also possible to carry out the treatment in such a way that no water repellency is observed but a considerable increase in wet strength is obtained. These experiments were made with very thin filter papers known as 'Stilex' (used in the filtration of milk). Their wet strength is very low. With liquid methyl ester we observed in five different experiments increases in the wet strength compared with untreated paper of 16–19 times.

It was also observed that treated filter papers are very resistant towards alkaline solutions. It is possible to filter 10–45 per cent sodium hydroxide.

The water-repellency effect is probably of the same nature as that observed by treating paper or other materials with silicones[3,4,5]. The increase in wet-strength, on the other hand, is very likely caused by cross-links of silicon atoms formed between the cellulose chains.

Further details will be published elsewhere. I wish to express my thanks to Prof. The Svedberg for his interest in the work. I am also indebted to Dr. Ragnar Winbladh for including this investigation among the research projects of Centralbolaget.

Electrical Breakdown of Organic Insulation by Electro-chemical Reactions

RECENT work on impregnated cellulosic insulating materials has shown that electrical breakdown under moderate D.C. stress is normally of an electrochemical nature. Leakage current is conveyed by ions originating from slight dissociation of the insulating material or from traces of impurities such as moisture or organic acids. The ions on discharge at the electrodes are in a chemically highly active (nascent) condition and may attack the insulation. The attack at the cathode is by nascent hydrogen and, with some forms of insulation, this has serious consequences.

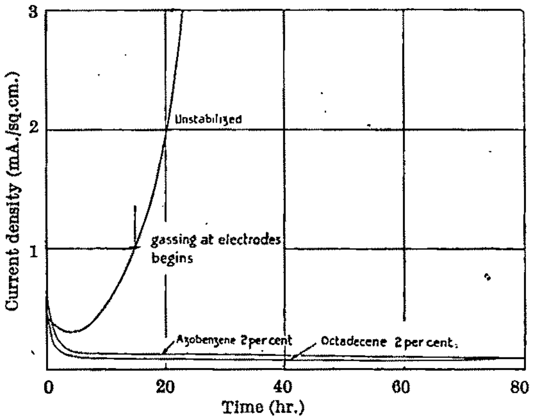
For example, when chlorinated hydrocarbons form part of a dielectric, cathodic reduction leads to release of hydrogen chloride, which itself dissociates in the dielectric, and may result in cumulative increase in current density and chemical attack upon the electrodes or other components of the dielectric.

Egerton and McLean[1] and Berberich and Friedman[2] have shown that the rate of deterioration of capacitors having a dielectric consisting of paper impregnated with a chlorinated hydrocarbon is decreased by the addition of small amounts of the following compounds: quinones, certain nitro-aromatic compounds, maleic anhydride, sulphur, aromatic azo-compounds and benzil. The action of these materials is known as 'stabilization' and has been attributed to formation of a protective film upon the electrodes[1] or a co-ordination complex between the stabilizer and aluminium chloride produced during the deterioration[2]. It is here suggested that a more likely mechanism is that the stabilizer combines preferentially with the cathodically produced hydrogen, without formation of harmful secondary products, thus shielding the dielectric medium from attack.

The experimental evidence in favour of the latter theory is as follows.

(1) All the substances listed as stabilizers are readily capable of reduction, and electrolytic reduction is found to take place under suitable conditions. Thus, we have found that when capacitors which have been stabilized with anthraquinone are opened after use under D.C. stress, under conditions which prevent reoxidation, the reduction product, oxanthranol, is produced. The same substance is found at the cathode on electrolysing acidified alcohol containing anthraquinone. Azobenzene is similarly reduced to hydrazobenzene.

(2) Trichlorbenzene – alcohol mixtures containing a little moisture, when electrolysed at room temperature, increase rapidly in conductivity, with formation of hydrogen chloride, after an initial induction period. Addition of a stabilizer greatly increases the induction period, irrespective of whether aluminium, tin or platinum electrodes are used. Mean conductivity – time curves using platinum electrodes are shown in the accompanying diagram.



Electrolysis of trichlorbenzene – alcohol mixture (50/50 vol. + 2 per cent water) with and without addition of azobenzene or octadecene using platinum electrodes. Stress, 150 volts (D.C.) per cm.

(3) Paper dielectric capacitors impregnated with chlordiphenyl are capable of stabilization, even when made with platinum electrodes. The lives of such capacitors have been extended more than ten times by the addition of azobenzene or octadecene.

(4) Readily hydrogenated aliphatic hydrocarbons, for example, octadecene (see (2) and (3) above), are effective stabilizers. Compounds of this type have not previously been cited as stabilizers and were investigated because of their unsaturated character and ease of hydrogenation.

It can be predicted that any readily reducible compound will stabilize, provided that neither it nor its reduced form appreciably ionizes in solution in the insulating material.

A detailed account of this work will appear elsewhere and further work is in progress.

Beta Spectrum of Tritium

THE β-spectrum of tritium (${}_1\mathrm{H}^3$) is of particular interest because: (1) the relatively simple structure of the ${}_1\mathrm{H}^3$ nucleus makes it well suited to a test of the Fermi theory of β-decay; (2) the unusually low energy of the β-particles means that the shape of the spectrum near the upper limit is an extremely sensitive function of the rest mass of the neutrino if the Fermi theory is confirmed; (3) a theoretical discrepancy[1] exists between the half-life[2] and the upper energy limit, as recently measured[3]; (4) the mass difference (${}_1\mathrm{H}^3 - {}_2\mathrm{He}^3$) can be accurately determined.

We have developed a new technique for rapid and accurate detection and energy measurement of β-rays, conversion electrons, γ-rays and X-rays (including *K*-capture radiation) from weak sources. The method, applicable to radiations of energy of 0·5–150 keV., uses a proportional counter, containing an argon – methane mixture at a pressure of one atmosphere or more, connected to a linear amplifier of high gain. The output pulses are applied to the deflecting plates of a cathode ray tube and recorded by a moving-film camera. The size of the pulses is a true relative measure of the energy of the ionizing radiation involved, provided that the range of the ionizing particle within the counter is small compared with its dimensions. The histograms of such pulses show that the resolving power of the apparatus is very good.

Radiation of known energy is used to calibrate the apparatus; for example, the fluorescence radiation of copper has been found to be very suitable. The counting system has been checked over the range 6–50 keV. with radiation from radioactive sources and with X-rays, and very good agreement with known values was obtained. The large Auger effect in argon[4] ensures that practically the whole energy of a photon is converted into the kinetic energy of the photo-electrons which it releases from the gas.

The amplifier gives a measurable pulse about three times the peak noise voltage for a charge of 1,500 electrons at the first grid. Thus, with a gain in the gas of as little as 100—ensuring strict proportionality—a measurable pulse is secured from the formation of 15 ion pairs; the system, therefore, can readily measure electron energies down to 500 eV.

Fig. 1 gives a typical calibration spectrum of the fluorescence X-radiation of copper, showing the *Kα* and *Kβ* groups clearly resolved. The counter contained sufficient tritium gas to give about 5,000 counts per minute, and the X-radiation is superimposed on part of the ${}_1\mathrm{H}^3$ β-spectrum; the distribution shows that a pulse size of 47·5 units (arbitrary scale) corresponds to the *Kα* groups of copper, taken[4] as 8·01 keV. Fig. 2 shows the tritium spectrum for the range 1–18 keV. taken under the same conditions. The background, about 15 counts per energy interval, has been subtracted and the energy scale set up according to the above calibration; about 40,000 pulses are analysed. The upper limit is found to be 16·9 ± 0·3 keV., which is considerably higher than a recent estimate[3] of 11 ± 2 keV.

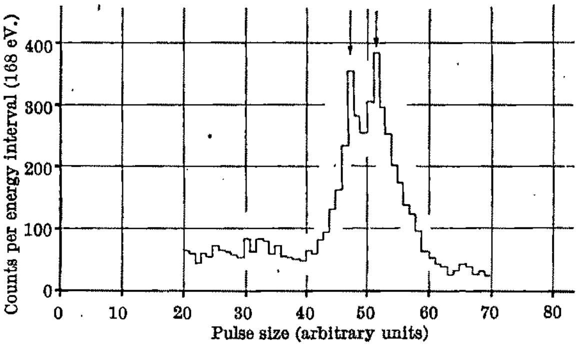

Fig. 1

The calculated Fermi distribution for ${}_1\mathrm{H}^3$ of end-point $\sim$ 17 keV. shows a maximum at about 2 keV.: a maximum appears on our experimental curve near 2·5 keV., but we find that it is definitely rather wider than the maximum of the theoretical curve. We have made various experimental tests which confirm that the shape at low energies is not due to absorption of hydrogen by the wall with consequent loss of range of the emergent electron. The radioactive gas could be pumped off readily and completely, and the shape of the spectrum was found to be independent of the ratio of surface to volume for the counter. Taken with two cylindrical counters of effective lengths 12 cm. and 4·5 cm. and diameters 6·7 cm. and 2 cm. respectively, the results were identical within experimental error. The histograms given here were obtained with the larger tube. The range of the most energetic electrons of ${}_1\mathrm{H}^3$ is negligible compared with the dimensions of this counter. It seems certain that in this work the departure from agreement with Fermi at low energies cannot be ascribed, as in a number of previous spectrographic investigations with other sources, to the ordinary limitations, in particular the thickness and support of the source and the absorption at the window of the detector. This disagreement may be rather important in view of the relative simplicity of the Fermi theory for the light nucleus ${}_1\mathrm{H}^3$.

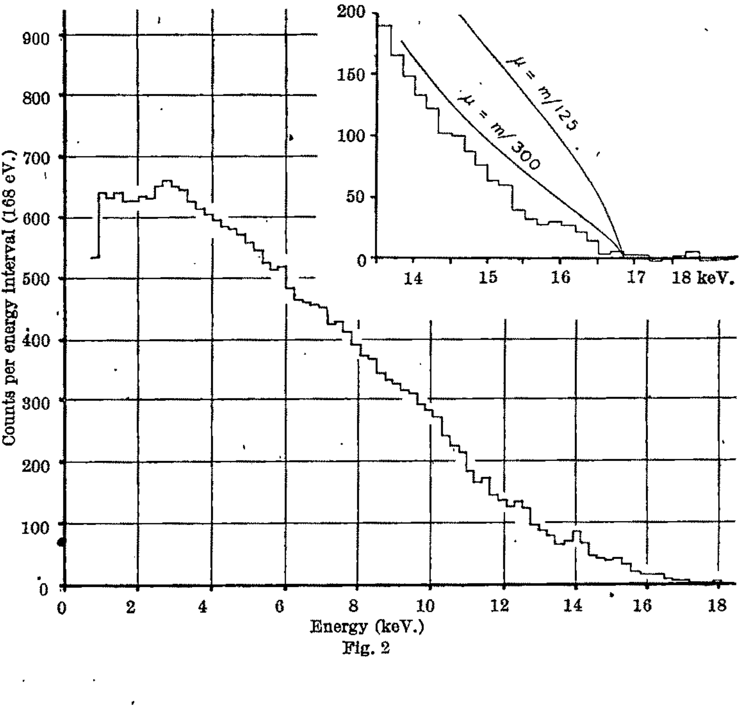

Fig. 2

We have considered the possibility of the spectrum being complex, but its shape seems to rule out such an explanation. The detector is such that γ-rays following emission of β-particles of a hypothetical softer group would have given rise to a readily observable discontinuity on our histograms, since the efficiency of detecting such γ-rays would be ~ 25 per cent. The life-time of the excited state of $_2He^3$ would have to be appreciably greater than the life-time of $_1H^3$ to escape detection.

In view of the above considerations, it is possible to justify the application of neutrino theory to the upper end of the spectrum in the usual manner. However, we have shown in the inset figure two curves calculated for neutrino masses $\mu = m/125$ and $m/300$, and comparison of these with experiment seems to indicate that μ is less than $m/300$.

Since there is no evidence of γ-radiation following the β-emission, we can write the mass equation (atomic) as

$$_1H^3 - {}_2He^3 = 0{\cdot}000018.$$

It is a pleasure to thank Prof. P. I. Dee for his valuable advice throughout the work. We are grateful to Mr. B. Touschek for elucidating various theoretical points.

Velocity of Photons

I AM seeking an answer—or a reference to an answer—to an apparent paradox arising out of the theory that light is transmitted in the form of photons, which may be illustrated by the following concrete example.

Atoms of sodium on Sirius, vibrating so as to give out a definite spectral line, send out photons each of which contains the amount of energy ($h\nu$) corresponding to such vibration. These photons, therefore, are identical in all respects, since their energy content is dictated solely by local conditions and clearly cannot be influenced by what may be their ultimate targets, if any. Two such photons are directed towards the solar system, and one arrives at the earth which is approaching Sirius at 30 miles per second, and the other on Mars which happens to be receding from Sirius with the same velocity. What physical factor causes these photons to give different optical effects since (*a*) their internal energies are identical, (*b*) their speeds are also identical, since they arrive at their targets with the velocity (absolute and relative) of light, which is independent of the motions of source and observer ?

I have searched in vain for any explanation of the Doppler effect which recognizes (*a*) that light moves in the form of photons, and (*b*) that the velocity of the photons is independent of that of their source.

Personally, I can see no answer to this query unless the theory as to the travel of light in the form of photons is profoundly modified.

Latitude Effect and Meson Decay

IT has been pointed out recently[1] that the height of the atmospheric layer (100 mb.) in which most mesons are supposed to be produced decreases from the equator towards the poles. The decay of the mesons causes a corresponding increase in cosmic ray intensity.

A first calculation of this effect based on a decay constant[2,3] $L = 5$ km. seemed to indicate that the greater part of, if not all, the latitude effect might be explained thus. A more precise estimation of the 'atmospheric latitude of effect' as distinguished from the geomagnetic can be obtained as follows. The altitude of the 100-mb. level varies not only with geographic latitude but also with the seasons. It is assumed that the seasonal effect of cosmic rays as observed in latitudes where the geomagnetic effect is small, if not nil, is entirely due to these variations. This is called the 'atmospheric seasonal effect'. Further, the 'atmospheric latitude effect' is defined as the variations in cosmic ray intensity caused by the differences at different geographic latitudes in the yearly averages of the heights at which mesons are produced; all measurements having been reduced before to standard atmospheric pressure. The ratio of the two effects can be obtained by comparing the seasonal variation of the meson-producing layer with its average latitudinal variation between the equator and the latitude under consideration. The influence of a differing energy spectrum is neglected.

Measurements with shielded ionization chambers at sea-level[4,5] and tables and graphs of the altitude of the 100-mb. level[6,7] supply all the data required. These are tabulated in columns 1, 2, 3, 4.

1		2	3	4	5	6	7	8
Sydney	34° S.	0·20	2·0	1·3[4]	1·3	1·5	3·0	13
				1·1[5]	1·7			
Vancouver	50° N.	0·35	1·2	3·1[4]	3·1			
				1·2[5]	1·8	2·5	3·0	14

Column 2: Difference summer–winter of the height of the 100-mb. level in km. (dH).
3: Difference equator–40° lat. of same level divided by value of column 2.
4: Observed difference summer–winter as percentage of cosmic ray intensity.
5: Adjusted column 4.
6: Average of column 5 (dI/I).
7: Atmospheric latitude effect equator–40° lat. as percentage of total cosmic ray intensity, obtained by multiplying columns 6 and 3.
8: Decay constant L in km. obtained by dividing column 2 by column 6.

The values for some of the seasonal variations of cosmic rays have to be adjusted for the difference in the period over which they and the stratosphere data were averaged (column 5). The decay constant L was calculated from the relation $dI/I = - dH/L$, in which I is the cosmic ray intensity and H the height. Taking into consideration the wide differences possible in the measurements of the heights at times as well as localities far removed from the cosmic ray measurements, it is satisfactory to find that the results obtained for the decay constant lie within the range[8,9] of 9–19 km. of the most reliable determinations. In conclusion, it can be stated that the atmospheric latitude effect is about three per cent of the total intensity, that is, one third of the total latitude effect between the equator and the knee at sea-level. This reduction of the geomagnetic latitude effect, if confirmed, will require a revision of the energy spectrum of the primary cosmic rays.

The east–west effect, the nearly constant geomagnetic latitude of the knee, demonstrate also that a great part of the latitude effect is of magnetic origin.

When an attempt was made to obtain accurate corrected values for the geomagnetic effect alone, it was found that the necessary experimental data did not exist. The previously used temperature correction[4,5] presupposes at least a very high correlation between sea-level temperature and the altitude of the 100-mb. level, which is not proved. On the other hand, this correlation could mask a geomagnetic effect extending beyond the knee, the correlation between sea-level temperature and latitude being of the order of 0·9 and more.

The height of the meson-producing layer will depend not only on latitude and season but also on other local meteorological and geographical factors, distribution of land and sea, mountains and so on. To achieve a reliable and accurate correction, it is clearly necessary to obtain simultaneous cosmic ray and high-atmosphere data at the same locality. A new world-wide survey made under these conditions might reveal that some of the unexplained features of Compton's can be explained as a 'local atmospheric effect' and do not represent a variation in primary intensity.

Results obtained during the 1948 cruise of the *Wyatt Earp*, the ship of the Australian Antarctic Expedition, will be published shortly in the *Australian Journal of Scientific Research*. The measurements extend to within 200 miles of the magnetic south pole.

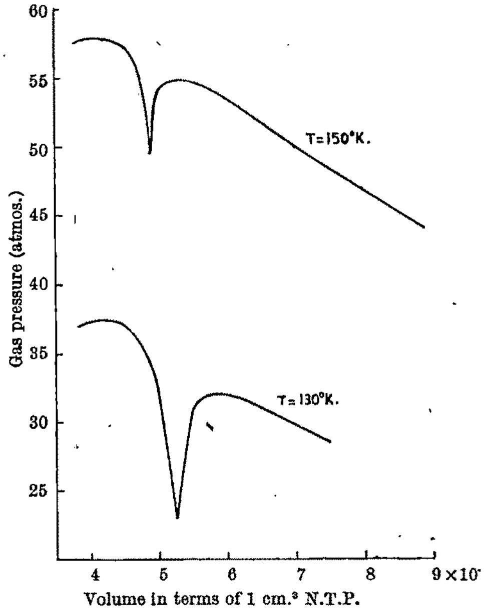
An Approximate Equation of State

IN a previous communication which appeared in *Nature*[1], Prof. Max Born and Dr. H. S. Green gave an account of a general kinetic theory of condensed matter (see also refs. 2–5). A new equation of state was derived which covers both phases, liquid and gas. Some numerical results (to be published in detail elsewhere) have now been obtained.

The theory shows that the difference between the liquid and the gas corresponds to the existence or non-existence of real roots of a certain transcendental equation. This was in the original form an integral equation, but has now been reduced, by using a suitable expansion, to an algebraic equation with a unique analytic continuation, so that the definition of the complex roots is unambiguous.

The theory of condensation developed by Mayer[6] and others[7,8] is confirmed by the present theory to the extent that a divergence of the cluster series is found, which is intimately associated with the process of condensation. Concerning the exact point at which this divergence occurs, detailed calculations do not confirm Mayer's contention that it happens at the density of the saturated vapour. The isotherm is continued into the metastable region above this density, rising to a maximum and falling to a subsequent minimum as the density is increased, much in the way foreshadowed by van der Waals more than fifty years ago. The point of divergence is fou to be at the minimum of this curve, which separa the metastable states of the liquid from those of t gas.

A numerical computation has been carried out argon using the Lennard-Jones[9] potential; t isotherms have been calculated, one for the empiri critical temperature ($T = 150°$ K.) and one for lower one ($T = 130°$ K.). The accompanying gra shows the result.



Concerning the absolute values, one can comp the experimental critical point with the situation the maximum in the gas region of the first cur The results are given in the table, for 1 cm.³ of at N.T.P.

	Experimental	Calculated
Pressure	50 atmospheres	54 atmospheres
Volume	0·0034 cm.³	0·0052 cm.³

A conspicuous feature of the curves is the f that for small volumes they do not ascend stee but have a maximum and fall again. This may due to the crudeness of the approximation actu employed (namely, only the first three roots of transcendental equation were taken into accou But it seems to be quite possible that it is an indi tion of another range of unstable states separat the liquid from the solid. This has to be investigat

Exact numerical prediction would need a gr amount of computation. It seems more import to use the same method for calculating the ra distribution function, which can be compared direc with X-ray experiments. This will be done i paper in due course.

ELECTRON OPTICAL OBSERVATIONS ON CHROMOSOME STRUCTURE IN RESTING CELLS

By FERNANDO CALVET*, BENJAMIN M. SIEGEL†, and DR. KURT G. STERN
Polytechnic Institute, Brooklyn, N.Y.

RESENT knowledge of chromosome structure is based chiefly on observations made on fixed prerations of large *mitotic* chromosomes or of the -called giant chromosomes in the salivary gland of rtain diptera with microscopes utilizing visible or tra-violet light[1]. A preliminary account has cently been published of electron microscope udies on large plant chromosomes[2]. Little or thing is known concerning the structure of chromomes in *resting* cells beyond the fact that they are esent in the form of exceedingly slender threads hromonemata) or of the so-called chromatin netork[3].

Following preliminary observations, made in our boratory in collaboration with Miss Judith hryver[4], we have studied in some detail the romatin structure present in the resting nucleus of lf thymus lymphocytes. An RCA ectron microscope of the universal pe, equipped with a self-biased ectron gun and an objective pole ece corrected for asymmetry[5], was ed in this work.

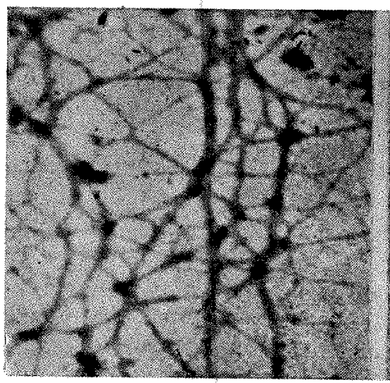

Fig. 1

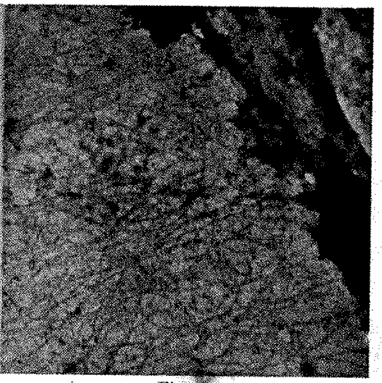

Fig. 2

Fig. 1. Chromatin network of thymus lymphocyte, prepared by rupture in high vacuum. Overall magnification, × 20,000

Fig. 2. Ultra-fibrils, obtained by lanthanum acetate treatment of chromatin network of thymus lymphocyte. Overall magnification, × 20,000

Pure suspensions of thymus lymphytes were obtained by mincing esh or frozen tissue under 0·9 per nt sodium chloride solution, straing the resulting milky suspension rough gauze, sedimenting the cells a centrifuge at low speed, and suspending them in physiological lt solution. The intact lymphytes have a diameter of approxiately 7 μ, while the nuclei measure 6 μ. Owing to their relatively ge size, the cells as well as the clei are opaque when examined rectly in the electron microscope. romium-shadowed replicas[6] prered from slowly dried, intact ymus lymphocytes show a *pitted* surface. Its pearance may, to some extent, reflect the undering structure of these cells, or it may represent artefact produced by shrinkage upon drying in high vacuum.

When the lymphocytes are ruptured by quick ying in a special, high-vacuum chamber, or when ey are damaged mechanically by placing a susnsion of the cells in physiological salt solution in a aring blendor, a mass of cellular contents escapes rough the ruptured cell membrane. After the toplasmic components of this mass, which usually mains connected with the 'ghost' of the cell, have en dissolved by washing with physiological saline, e chromatin nature of the residue adhering to the llodium film on the copper screen can be demonated with the aid of nuclear stains, for example, etocarmin or Feulgen stain, and the optical croscope. The examination of the same material, but without fixing or staining it, in the electron microscope reveals a loose mesh of cross-linked fibres of indeterminate length and of varying width, ranging from about 200 A. to 700 A. (Fig. 1). With the exception of dense spots which are situated at cross-over points of the fibres, little, if any, fine structure may be discerned in them. It is believed that the material shown in Fig. 1 represents the *chromatin network* as it exists in the nucleus of resting cells, in agreement with the classical view[3] according to which the 'thread type' nuclei of the cells of glandular tissues consist essentially of a reticulum of chromatin threads distributed in a fluid nucleoplasm. While the nucleoprotein nature of these fibres appears established through their origin, solubility, staining as well as other chemical properties, and their high density towards electron beams, their relationship to or identity with the *chromonemata* or 'resting chromosomes' remains to be determined. The examination in the electron microscope, at low power, of the particles isolated from thymus tissue by repeated use of the Waring blendor at low and high speed according to Mirsky and Ris[7], and designated as 'resting chromosomes' by these workers, indicates that they represent random fragments of the chromatin network resulting from mechanical shearing action rather than preformed units of well-defined structure.

Lanthanum salts are known to possess a high affinity for nucleic acid and have previously been used for analytical purposes and ultra-violet microscopy of chromosomes (cf. T. Caspersson[1]). When thymus lymphocytes are treated with lanthanum acetate after the cells have been ruptured mechanically or by exposure to a high vacuum, the fibres composing the chromatin network are further resolved into bundles of fine *ultra-fibrils* of fairly uniform thickness of 80–100 A. (Fig. 2). In addition, the

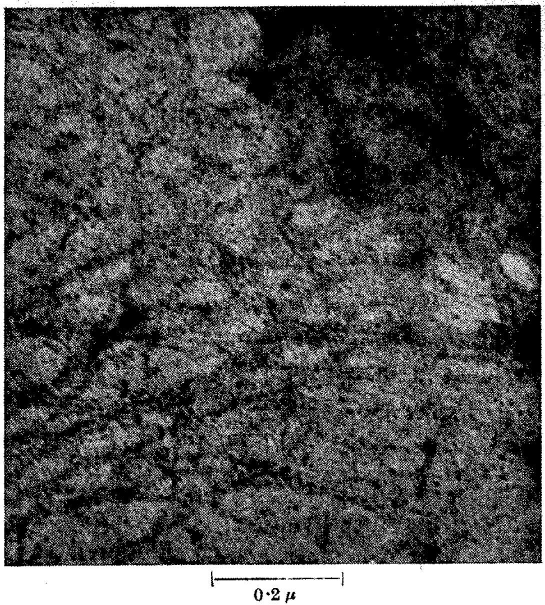

Fig. 3. Photographically enlarged area from Fig. 2, showing fine structure of lanthanum-stained ultra-fibrils. Overall magnification, × 80,000

lanthanum reagent acts as an 'electron stain' on the nucleoprotein ultra-fibrils and permits the detection of details which cannot be seen in unstained preparations. (Structural details of muscle and collagen fibrils have been brought out by electron-staining with phosphotungstic acid by F. O. Schmitt *et al.*) Carefully focused electron micrographs of lanthanum-treated fibrils show that they possess definite fine structure of a high order of regularity. This is evident from Fig. 3, which represents a photographically enlarged area of Fig. 2.

The inspection of a number of electron micrographs of this type suggests that the banded appearance of the lanthanum-stained ultra-fibrils is produced by the *coiling* of a fine thread to form long helices. The apparent width of the individual 'bands' or 'disks' is about 30–40 A., spaced at approximately equal intervals from each other. It is of interest to note that X-ray diffraction measurements on a synthetic albumin thymonucleinate complex[8] and ultracentrifuge and diffusion experiments on thymonucleohistone particles in 0·8 *M* sodium chloride solution[9] have yielded estimates for the width of such molecules of 23 A. and 40 A. respectively. Thus it would appear possible that the structures reproduced in Figs. 2 and 3 represent spirals formed by individual desoxyribonucleoprotein molecules in combination with lanthanum ions. A fine structure of this type has recently been postulated on theoretical grounds by one of us[10].

This work was supported by a grant from the Brooklyn Cancer Committee, the assistance of which is gratefully acknowledged.

EVOLUTION OF THE DENTITION OF THE ORANG-UTAN

DURING his searches for the remains of th forerunner of man, beginning in 1887 an covering a span of more than twelve years, the lat Prof. Eugène Dubois collected prehistoric and foss teeth of the orang-utan in the islands of Sumatr and Java. Dubois has always been very guarded i his comments on the prehistoric teeth; but th fossil have received much attention because the were ascribed to *Pithecanthropus erectus*. The result of a recent study made by me on this material* ar summarized here.

Dubois' explorations started in prehistoric cave in the Padang Highlands, Central Sumatra. Th cave fauna appeared to be characterized by th relative abundance of the orang-utan (now confine to the northern parts of the island, and to Borneo and contained no extinct species. In general, th cave teeth differ from their recent homologues b their greater average size. In several cases I fin that the differentiation which the species has unde gone since the deposition of their teeth in the cave has proceeded to a stage equal to that of goo subspecies.

More than three thousand isolated subfossil teet of the orang-utan were collected by Dubois in centra Sumatra, representing some three to five hundre individuals. The study and statistical analysis this collection has revealed certain interesting trenc in the evolution of the dentition. They stamp th prehistoric orang-utan, which may be known *Pongo pygmæus palæosumatrensis*, as a larger an more simian form than the recent orang. On th average, the teeth of the prehistoric orang-utan a 16 per cent larger than the recent. The later incisors, both in the upper and in the lower jav were relatively less reduced in size. The canines we larger and less hypsodont than the recent, and th sexual difference in size was even more pronounce in the prehistoric than it is in the present-day oran utan. The anterior lower premolar was larg relative to the posterior. The excess in size of th second molar over the first and the third, a typical simian feature that is met with in early stages the evolution of the hominid dentition, was mo pronounced in the prehistoric orang-utan than it now.

The two upper molars from the middle Pleistocen at Trinil in Java ascribed to *Pithecanthropus erect* by Dubois have been stated to belong to an oran utan by Miller, Weidenreich and Von Koenigswal The careful study of the original specimens leaves shadow of doubt as to their belonging to the oran utan. They can be determined as representing sin. and M^4 dext. respectively, most probably derive from one and the same individual. The fossil Javane teeth are not larger than their recent homologues.

Pleistocene teeth of the orang-utan have be described from southern China by Pei, Von Koenig wald and Weidenreich. In contradistinction to t Pleistocene teeth from Java, however, the fos Chinese teeth are decidedly larger than the recen and they even differ from those of *Pongo pygmæ palæosumatrensis* in their distinctly larger size. lower canine from the Hoshangtung cave in Yunna

* "Prehistoric Teeth of Man and of the Orang-utan from Cent Sumatra, with Notes on the Fossil Orang-utan from Java and Southe China." By Dr. D. A. Hooijer. *Zool. Med. Museum, Leyden*, 175–301, pls. I-IX, 2 diagrams.

China, described by Weidenreich, is made the type of a new subspecies, *Pongo pygmæus weidenreichi*, on account of its being still bigger and less hypsodont than its homologue in *Pongo pygmæus palæosumatrensis*. It has thus become evident that the orang-utans which roamed the Pleistocene forests in southern China and in Java respectively were racially different, the continental form being larger than the Javanese. The fossil canine from Yunnan is structurally ancestral to that of the subfossil Sumatran orang-utan; but the relationship between the fossil Chinese and the subfossil Sumatran race cannot be regarded as firmly established on the base of isolated teeth. At any rate, the Pleistocene forerunner of *Pongo pygmæus palæosumatrensis* must have been larger than that of Java, the island in which the orang-utan is now extinct. The Javanese orang-utan was already of the small size of the present-day Sumatran and Bornean orang-utan in the Pleistocene, and it might very well have decreased in size still further up to the present, a condition that is paralleled by other species in which the record is more complete.

The dental characteristics of the recent orang-utan, which have been used in so many comparative studies on the dental anatomy of man and the apes, have now been shown to be the result of an evolutionary change dating from the emergence of the species early in the Pleistocene. The prehistoric Sumatran and the fossil Chinese orang-utan are still further removed in dental structure from man in the points which distinguish the recent orang-utan dentition from that of modern man. D. A. HOOIJER

CARNEGIE TRUST FOR THE UNIVERSITIES OF SCOTLAND

THE forty-sixth annual report of the Carnegie Trust for the Universities of Scotland, Dunfermline, covers the academic year 1946–47 and again includes as appendix the new scheme for the award of fellowships and scholarships which came into effect on October 1, 1947. Grants made under the eighth quinquennial distribution for the period October 1, 1947, to September 30, 1952, and detailed in an appendix, include £33,650 to the University of St. Andrews, £13,350 to University College, Dundee, £70,000 towards the erection of the final portion of the Chemistry Institute at the University of Glasgow, £47,000 towards the cost of the new Chemistry Department at the University of Aberdeen, £23,000 for library expenditure and £25,000 for capital expenditure on the university schemes on the Bush and Dryden estates at Edinburgh, the grand total being £234,000 to the universities and £36,000 to extra-mural colleges. Special attention is directed to the observations in the report on assistance to students. The Executive Committee, examining the new situation created by Circular 106 of the Scottish Education Department, considered that until the amount of the bursary awarded by the education authorities had been ascertained for each individual applicant to the Trust, it would be premature to make any extensive alterations in the system adopted for the award of Carnegie Trust grants. Nevertheless, the Executive Committee expected that a turning point in the administration of the Carnegie Trust, so far as half its annual income is concerned, may have been reached, and that very considerable sums at present absorbed in assistance with class fees will be liberated for new projects. The amount disbursed for this purpose during 1946–47 was £51,072 to 3,068 beneficiaries, as against £55,109 to 3,250 beneficiaries in 1945–46.

In the report on the work of investigators during the year, special reference is made to the work of the following: J. L. Miller, on various aspects of high-voltage engineering; Eric Reid, on the diabetogenic principle of the anterior pituitary body; A. M. Mathieson, on the use of X-rays for the study of the structure of complex sulphur compounds and of anthracene; J. C. Robb's measurement of the rate of addition of atomic hydrogen to an unsaturated hydrocarbon; and N. Grassie, on the thermal degradation of high polymers of the polyvinyl type. N. Grassie has devised a molecular still of very high performance and has thrown much light on the mechanism of depolymerization; R. I. May has made rapid progress in the study of polymerization in the gas phase; and A. McLaren in investigations of the role of radicals in polymerization. Mention is also made of the 'cruciform' macromolecule compounds, obtained by C. W. Youngson, of D. Ellis and G. T. Dickson's results in the study of the molecular structure of colchicine, and of S. C. Reid and R. C. Stuart's work on the chemistry of mandelic acid derivatives. In his work on the Silurian rocks of the Pentland hills, Dr. A. Lamont has made a major contribution to geology. Dr. D. B. McIntyre has completed his work on the north-west part of the Loch Doon Plutonic complex and is now studying granitization phenomena in the Alps. Dr. N. Holgate has investigated the igneous rocks of the Glen Bervie complex, and Mrs. E. M. Knox's research has revealed the presence of several new types of microspores in the coals of the Limestone coal group of both the Fifeshire coalfield and the Central coalfield of Scotland.

The report of the Superintendent of the Laboratory of the Royal College of Physicians refers to Lieut.-Colonel W. F. Harvey's microscopic investigation of his collections of sections of human tumours, Dr. J. C. Lees and T. W. Lees' tests in mice of the tumour growth-inhibiting power of ten representative drugs, Dr. J. C. Lees and W. W. Park's collection of data regarding 120 cases of carcinoma of types usually affecting older patients but occurring at 30 years or less, and Dr. E. K. Dawson's histological investigations. Work under Dr. W. O. Kermack has been directed chiefly to the synthesis of compounds of possible interest as chemotherapeutic agents; Miss B. Cairns has worked on the synthesis of halogenated 1-azanthracenes, such as 9-bromo-2:4-dimethyl-1-azanthracene, and Dr. McKail on benzthiazoles containing an amino-group in the benzene ring. Mr. Bryce Douglas extended his research on *p*-phenanthrolines and related compounds to the synthesis of derivatives containing a basic side-chain in the 4-position and a chlorine atom in the 9-position. Dr. R. A. Miller is working on the determination of the conductivity and chloride content of human mother's milk throughout the lactation period both under normal and abnormal conditions, and Col. Glen-Liston and Dr. F. Chisholm's work on leucorrhœa has been completed, as has Dr. R. S. Barclay's work on the course of mortality and fertility in Scotland during the past eighty years.

The appendixes include a list of publications by fellows, scholars and recipients of grants received since September 30, 1946.

FIFTH COMMONWEALTH ENTOMOLOGICAL CONFERENCE

BECAUSE of the War, thirteen years have elapsed since the last Commonwealth Entomological Conference was held in London, and there is no doubt that the recent fifth Conference, which ended on July 29, has been the best attended and one of the most successful of the series. There were forty-two delegates, representing the United Kingdom, Canada, Australia, New Zealand, India, Southern Rhodesia and various Colonial territories, and the open meetings were attended also by large numbers of entomologists from Great Britain and overseas.

The first day was devoted to a discussion on insecticides and their application. This is the first time that this topic has appeared on the agenda of a Commonwealth Entomological Conference, and it was the only one to be given a full day.

The discussion on recent developments in insecticides was opened by Dr. R. A. E. Galley, scientific secretary to the Insecticides Development and Research Committee. He summarized the present knowledge on synthetic insecticides, many of which are still in the early experimental stage. Particular interest lies in the development of systemic insecticides which are absorbed by plants and thereafter toxic to insects which feed on them.

Dr. V. B. Wigglesworth, director of the Unit of Insect Physiology of the Agricultural Research Council, in a discussion on the mode of action of the new insecticides, said that D.D.T. if injected internally was almost equally toxic to insects and vertebrates. The reason that the former are so readily affected if they come in contact with D.D.T.-treated surfaces, while the latter are unharmed, is because of the readiness and rapidity with which absorption takes place through the insect cuticle. An account of Canadian experience with the new insecticides was given by Mr. W. A. Ross, of the Canadian Department of Agriculture, who stated that, of them, D.D.T. was the one most extensively used. Because of the great increase in the importance of orchard mites following the use of D.D.T., a search for efficient acaricides is one of the principal problems of fruit insect research in Canada. Several promising ones have already received preliminary investigation.

A discussion on the application of insecticides from the air was opened by Dr. D. L. Gunn, of the Anti-Locust Research Centre. After mentioning, the question of costs, Dr. Gunn spoke of the importance of ensuring a sufficiently homogeneous coverage of the target area. He pointed out that while a great deal of publicity has been given to aircraft spraying, and while in certain circumstances it would undoubtedly prove of value, little is yet known as to whether it can establish itself in competition with other methods.

Dr. W. R. Thompson, of the Commonwealth Bureau of Biological Control, who was to have opened the discussion on the biological control of insects, was unable to be present, and this session was opened by Mr. A. B. Baird, of the Canadian Department of Agriculture. Mr. Baird gave an account of the work of the Bureau of Biological Control since the last Conference, and spoke also of projects, mostly involving forest insect pests, with which he had been associated. Dr. W. Cottier, of New Zealand, followed with an account of the successful biological control of the small cabbage-white butterfly (*Pieris rapæ* L.) in New Zealand, and Dr. R. H. Le Pelley described the steps leading up to the control, by means of introduced parasites, of the coffee mealy bug in Kenya. This insect has at different times passed under different names, and this led to the search for parasites, made in the early stages of the investigation, being misdirected. When it was eventually realized that the injurious mealy bug was an undescribed species, native to the adjoining territory of Uganda, the parasite search became properly directed and was successful.

Some account of the general principles of the biological control of weeds by means of insects was given by Dr. D. Miller, of the Cawthron Institute, New Zealand. He also outlined particulars of some of the weed control projects which have been undertaken in New Zealand. These have been concerned with gorse, *Acæna* sp., and ragwort.

Mr. A. H. Strickland of the West African Research Institute, Tafo, Gold Coast, presented an able summary of special techniques relating to the estimation of insect populations in the field. He is of the opinion that little purpose is served by carrying out insect census work unless a preliminary detailed study has been made of the biology and habits of the species of insects concerned.

The discussion on recent developments in the control of stored products insects was opened by Mr. F. N. Ratcliffe, of the Division of Entomology of the Australian Council for Scientific and Industrial Research. He confined his remarks to wheat insects, and mentioned that the exploitation of D.D.T. and benzene hexachloride against grain insects is at present limited by the prevalent fear of their toxicity to human beings. In conclusion he stressed the importance of scientific men who work in this field having a knowledge of the manipulating conditions of the grain industry.

The subject of tsetse fly research and control was opened by Dr. T. A. M. Nash, and Dr. K. R. S. Morris took a prominent part in the discussion. Dr. Nash indicated the main lines in which research has been conducted; he remarked that each of the seven most important species of *Glossina* has different vegetational and climatic requirements, host preferences, and characteristic behaviour. While many methods of control have seemed promising, they have usually failed to produce complete elimination of the fly, with the result that as soon as control measures are relaxed, the fly density starts to rise.

In a discussion of the need for plant quarantine on a continental basis with special reference to Africa, delegates from various African territories gave particulars of the plant quarantine practice in their areas. The danger that might arise from uncontrolled air transport was emphasized.

Dr. B. P. Uvarov, who opened the discussion on locusts and grasshoppers, said that the outstanding result of the past twenty years of locust investigation is the firm establishment of the principle of outbreak areas, where the initial transformation of the solitary phase into the gregarious phase occurs and the first swarms of a plague-cycle are formed. While of recent years great strides have been made in discovering and applying effective palliatives, these must not be regarded as the end-point of the investigation; a radical solution of the problem must be sought in outbreak prevention, which needs more fundamental research.

Following the discussion on locusts and grasshoppers, the remaining part of the last afternoon was spent considering the recommendations of a Termite Sub-Committee which had been set up at an early stage of the Conference. These recommendations stressed the urgent need for research work on termites, particularly in the Colonies.

During the course of the Conference, delegates isited Whipsnade, Rothamsted Experimental Station, the Pest Infestation Laboratory of the Department of scientific and Industrial Research at Slough and the new entomological Field Station of the Imperial College of Science and Technology at Silwood Park. These visits, combined with certain social occasions, erved to give delegates that chance of informal iscussion which is perhaps the most valuable part of conference of this nature.

FOSSIL FLORA OF KERGUELEN ISLAND

THE biological interest of Kerguelen Island (latitude 49° S., longitude 69° E.) has been well known to botanists since 1847, when the young Joseph Hooker, as junior surgeon in Ross's famous voyage to the Antarctic in the *Erebus and Terror*, ontributed a description[1] of the botany of this island ained as the result of the expedition's first winter in he southern hemisphere (May–July, 1840). The xtreme poverty of the flora was its most noticeable eature, only eighteen species of flowering plants having been found by Hooker, and of these only eight overed any considerable expanse of ground. These ncluded the remarkable endemic crucifer, *Pringlea ntiscorbutica* (the Kerguelen Island cabbage), and a eculiar umbellifer related to the 'balsam bog' of the Falkland Islands. In comparable latitudes in the orthern hemisphere much richer floras were known o occur, the vegetation of Spitsbergen, for example, ontaining records in 1847 of forty-five species of owering plants on a comparable area. This, coupled ith the isolated position of the island in the middle the Antarctic Ocean, almost equidistant from outh Africa and from Australia, the presence of the ndemics and the vegetational affinity with the even ore distant Falkland Islands (off Cape Horn), are all oblems of lively plant-geographical interest to us as Hooker. Problems of equal interest are those raised the very marked changes of climate which have ccurred in these now desolate latitudes in fairly cent geological time. Hooker himself was profoundly impressed by seeing not only coal but also ssilized tree trunks of considerable size (one is pecifically mentioned by Ross as 7 ft. in circumference), although the existing vegetation cannot ast even a shrub, still less a tree, and this circumance was certainly one of the more powerful reasons hich predisposed him to the immediate acceptance the idea of evolution when it came.

The fossil woods brought back by the Ross expedin were not further investigated until 1921, when dwards[2] of the British Museum identified them as niferous." Shortly after this in 1934 Seward and nway[3] identified araucarian twigs and cone scales some macroscopic plant remains brought back by la Rue in 1931. This material also contained the nains of a moss and some indeterminate fragments dicotyledonous leaves and ferns.

An additional contribution is now available in the hth part of vol. 2 (pp. 129–142) of the Reports of the British, Australian and New Zealand Antarctic Research Expedition of 1929–31, published at Adelaide, 1947, under the title of "Plant Microfossils from the Lignites of the Kerguelen Archipelago by Isabel C. Cookson" (price 4*s*. 6*d*.). This is one of the few applications of the pollen analysis technique to fossil floras of the southern hemisphere, and though carried out on very limited material the results add greatly to previous knowledge while holding out considerable hope of more to come.

As was to be expected from Seward and Conway and from Edwards, araucarian pollen predominates. This is, however, not the only gymnosperm present. Five distinguishable species, undoubtedly belonging to the Podocarpaceæ though of less certain generic identity within that family, are listed under the form genera of *Disaccites* (*Podocarpidites*), *Polysaccites* (*Microcachryidites*) and *Disaccites* (*Phyllocladidites*). Angiospermous pollen is also present though more sparingly, five species only being so far recorded, three of which appear to be dicotyledons and two monocotyledons. In contrast there are ten varieties of Pteridophyte spores, probably of ferns, but not identifiable generically. There are likewise two species of ascomycetous fruit body.

While the available information does not yet permit of a generalized palæoecological statement to be made of this most interesting region it seems clear that gymnosperms and ferns predominate in the lignites so far examined, the age of which is on that account thought to be Tertiary. It is greatly to be hoped that this work will be further extended by a systematic study of additional collections and through the whole thickness of the deposits.

BIOLOGY AND CONTROL OF THE PEA MOTH

THE pea moth, *Laspeyresia nigricana*, Steph., is a widely distributed pest of garden and field peas in Great Britain and central and southern Europe, while in North America it has spread to all main pea-growing areas. In England the most severe losses occur in the pea-producing counties of Lincoln, Essex and Kent. D. W. Wright and Q. A. Geering, of the Horticultural Research Station and School of Agriculture, Cambridge, have published a useful paper on the biology and control of the pea moth (*Bull. Entom. Res.*, **39**, pt. 1, 57 ; 1948).

It appears that the moths show no special preference for ovipositing on or near the flowers or pods. The larva feeds on the young seeds in the pod and bores a hole through the pod-wall for the purpose of reaching its food. The hole heals over, however, in a few days, leaving a small blister. When fully grown the larva spins a thin, web-like cocoon immediately below the soil surface, wherein pupation takes place. The majority of the moths emerge before the end of July in the following year. Normally there seems to be only a single generation of this insect in Britain.

The trials that were carried out indicate that different varieties of peas differ widely in their susceptibility to attack. Furthermore, the infestation on the varieties is influenced by the amount of foliage cover that is available, the heaviest attacks being where the cover is most dense. Certain varieties of peas are well known to escape much of the severity of pea moth attack if sown early. Also, it appears that crops can be grown almost free from infestation if sown in the latter half of June or in July, since they will mature after the flight period of the moth.

It is recommended that the residue of crops picked green should be removed immediately and fed to stock, made into manure or ensilaged. This prevents the caterpillars from maturing in the seeds and pupating in the soil. Experiments using D.D.T. as an emulsion, or as a suspension, showed that considerable reduction in attack could be obtained with the concentration at 0·5 per cent by weight of D.D.T. It was found that the spray should be applied before egg-hatching has begun which, for sowings made in late April and in May, would be about 7–10 days after the first flowers appear on the crop.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturer (with high mathematical qualifications) in the Department of Mathematics—The Clerk to the Governors, Chelsea Polytechnic, Manresa Road, London, S.W.3 (August 28).

Histological Technician—Prof. A. Durward, Department of Anatomy, Medical School, The University, Leeds 2 (August 30).

Professors or Assistant Professors of Physics, Zoology, Botany, Mathematics, Geography, at the Higher Teachers' Training College, Baghdad; Professor or Assistant Professor of Mathematics, Assistant Professor of Physics, Professor of Biology, Lecturer or Assistant Professor of Psychology, Professor of Chemistry, at the Queen Alivah College; Dean, and a Professor of Electrical Engineering, at the College of Engineering; Assistant Professor of Economic Statistics, at the College of Commerce—The Cultural Attaché, Iraqi Embassy, 22 Queen's Gate, London, S.W.7 (August 31).

Assistant in Botany—The Secretary, The University, Aberdeen (August 31).

H.M. Inspectors of Factories—The Secretary, Ministry of Labour and National Service (O.E.11), 80 Pall Mall, London, S.W.1 (August 31).

Principal, a Professor of Civil Engineering, a Professor of Mechanical Engineering, and a Professor of Electrical Engineering, at the Government College of Engineering, Dacca—The High Commissioner for Pakistan, 14 Fitzhardinge Street, London, W.1 (August 31).

Senior Professional Officer (Ceramic and Refractory Research), University of the Witwatersrand, Johannesburg—The Director, Government Metallurgical Laboratory, c/o Mr. Victor Reid, South Africa House, Trafalgar Square, London, W.C.2 (August 31).

Chemist-in-Charge at the Royal Ordnance Factory, Pembrey, under the Ministry of Supply—The Ministry of Labour and National Service, Technical and Scientific Register, K Section, York House, Kingsway, London, W.C.2, quoting F.606/48A (August 31).

Chemists in certain Explosive Factories in the Directorate of Ordnance Factories under the Ministry of Supply—The Ministry of Labour and National Service, Technical and Scientific Register, K Section, York House, Kingsway, London, W.C.2, quoting F.605/48A (August 31).

Laboratory Assistant (Grade I) in the Department of Zoology—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1 (September 4).

Lecturer in Agriculture, a Lecturer in Dairying, an Assistant Lecturer in Botany, a Lecturer in Horticulture, and a Horticultural Adviser and Lecturer (junior post)—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow, C.2 (September 4).

Lecturer (Grade II or Grade III) in Electrical Engineering—The Secretary and Registrar, The University, Bristol (September 4).

Lecturer in Inorganic Chemistry—The Registrar, King's College, Newcastle-upon-Tyne (September 11).

Senior Organic Chemist in the biochemistry section for work on the organic constituents of fruit-bearing plants—The Secretary, East Malling Research Station, East Malling, Maidstone, Kent (September 11).

Head of the Instrument Division at the National Institute for Medical Research, Hampstead—The Secretary, Medical Research Council, 38 Old Queen Street, London, S.W.1 (September 11).

Assistant Lecturer, preferably with some experience in Radar research—The Registrar, University College, Hull (September 13).

Assistant Lecturers (2) in the Department of Civil Engineering—The Professor of Civil Engineering, Queen's University, Belfast (September 15).

Mullard Readership in Electronics at the Imperial College Science and Technology—The Academic Registrar, University London, Senate House, London, W.C.1 (September 15).

Professor of Power Stations in the Mechanical Engineerin Department of the Faculty of Engineering, Farouk I Universit Alexandria—The Director, Egyptian Education Bureau, 4 Chesterfiel Gardens, London, W.1 (September 15).

Senior Lecturer in Electrical Engineering at the Universit of Melbourne—The Secretary, Universities Bureau of the Britis Empire, 8 Park Street, London, W.1 (September 15).

Professor of Botany at Fouad I University, Cairo—The Directo Egyptian Education Bureau, 4 Chesterfield Gardens, London, W. (September 15).

Inspectors (Salmon and Freshwater Fisheries) in the Ministr of Agriculture and Fisheries—The Secretary, Civil Service Com mission, 6 Burlington Gardens, London, W.1, quoting No. 225 (September 16).

Senior Experimental Officer in an experimental researc establishment of the Ministry of Supply, near Salisbury—The Secretar Civil Service Commission, Scientific Branch, 27 Grosvenor Squar London, W.1, quoting No. 2256 (September 17).

Research Fellowship in the Turner Dental School—Th Registrar, The University, Manchester 13 (September 18).

Simon Visiting Professor, and Simon Research Fellowship for Advanced Study or Research in the Social Sciences—The Registra The University, Manchester 13 (September 29).

Agricultural Economists (3, one at each College)—The Secretar West of Scotland Agricultural College, 6 Blythswood Square, Glasgow C.2; The Secretary, Edinburgh and East of Scotland College Agriculture, 13 George Square, Edinburgh 8; The Secretary, Nort of Scotland College of Agriculture, 41½ Union Street, Aberdee (September 30).

Lecturer (ungraded) in Veterinary Parasitology—The Regis trar, Schools of Tropical Medicine and Veterinary Science, Th University, Liverpool (September 30).

Assistant Examiners in the Patent Office under the Board Trade—The Secretary, Civil Service Commission, 6 Burlington Ga dens, London, W.1, quoting No. 45A (September 30).

Chair of Mechanical Engineering, a Senior Lecturer Zoology, a Lecturer in Zoology, and a Technician in the De partment of Zoology, at Auckland University College, New Zealan—The Secretary, Universities Bureau of the British Empire, 8 Pa Street, London, W.1 (October 1).

Readership in Civil Engineering at King's College—Th Academic Registrar, University of London, Senate House, Londo W.C.1 (October 1).

Chair of Organic Chemistry at the Imperial College of Scienc and Technology—The Academic Registrar, University of Londo Senate House, London, W.C.1 (October 4).

Curator of the Auckland Zoological Park—The Office of th High Commissioner for New Zealand, 415 Strand, London, W.C. (Auckland, October 29).

Lecturer in Tropical Hygiene—The Dean, Liverpool Scho of Tropical Medicine, Pembroke Place, Liverpool 3, endorsed 'Lectur ship in Tropical Hygiene' (October 31).

Fellowships and Scholarships for the advancement of Extractio Metallurgy—The Secretary, Nuffield Foundation, 12–13 Mecklenburg Square, London, W.C.1 (November 1).

Demonstrator in Zoology—The Secretary-Registrar, Wy College, Wye, Kent.

Plant Physiologist to study the physiology of cocoa, with speci reference to water, nutrient and light requirements, and Plan Breeders to undertake the selection and breeding of cocoa types a varieties and progeny trials, at the West African Cocoa Resear Institute, Gold Coast—The Director of Recruitment, Colonial Offic Sanctuary Buildings, Great Smith Street, London, S.W.1.

Scientific Officer to deal with administrative aspects of resear —The National Coal Board, Establishments (General) Branch Hoba House, Grosvenor Place, London, S.W.1, quoting TT/68.

Graduate (or equivalent) as Assistant in Enquiry Laborator dealing with works problems submitted by member firms—T Printing, Packaging and Allied Trades Research Association, Rand Road, Leatherhead, Surrey.

Honours Graduate for work on engineering applications of flu mechanics—The British Hydromechanics Research Association, Petty France, London, S.W.1.

Laboratory Assistant (Grade II) for hygiene and bacteriolo department—The Secretary, King's College of Household and Soc Science, Campden Hill Road, London, W.8.

Scientists with research and practical experience in (*a*) Co Mining (Ref. TT/70), and (*b*) Coal Chemistry, analytical wo metallurgy or coal tar (Ref. TT/71)—The National Coal Boar Establishments (General) Branch, Hobart House, Grosvenor Pla London, S.W.1, quoting appropriate Ref. No.

Lecturer in Mathematics at the University of Otago, Dunedin The High Commissioner for New Zealand, 415 Strand, London, W.C

Chemist by the East African Industrial Management Boa Nairobi, Kenya—The Crown Agents for the Colonies, 4 Millba London, S.W.1, quoting M.N.21789/3E.

Laboratory Technician (male) in the Department of Chemic Pathology—The Secretary, Medical School, Guy's Hospital, Lond Bridge, London, S.E.1.

Managing Chemist to take charge of the Metallurgical Develo ment laboratories in the Department of Atomic Energy at Spri fields Factory, Salwick, Preston, a Chemist-in-Charge (must ha extensive metallurgical knowledge with experience in modern metho of metallurgical investigation), and Chemists to supervise expe mental work related to the metallurgical development involved the production of Atomic Energy—The Staff Section, Ministry Supply, Department of Atomic Energy, Risley, Warrington, Lancs.

Lecturer in Civil Engineering, and a Lecturer in Mechanic Engineering—The Clerk to the Governing Body, Battersea Po technic, Battersea, London, S.W.11.

Assistant Director (Metallurgical Development) in the Depa ment of Atomic Energy, Risley—The Staff Section, Ministry Supply, Department of Atomic Energy, Risley, Warrington, Lancs.

MEDICAL EDUCATION

MEDICAL education continues to be the subject of very lively discussion. In 1944 the Goodenough Committee issued its much-quoted report on the "Organisation of Medical Schools"[1]. A year ago an authoritative sequel appeared in the form of the General Medical Council's "Recommendations as to the Medical Curriculum"[2]. Newer and detailed proposals have now been published under the title "The Training of a Doctor" under the authorship of a Curriculum Committee that was set up in 1945 by the British Medical Association[3]. In the background, reaching far back over the years, are many other reports on the same subject. Before considering where the British Medical Association's proposals stand in relation to those of the Goodenough Committee and the General Medical Council, it is useful to consider for a moment why the medical curriculum is always under fire. For so it would seem to be if one compares medical with other university departments ; there has certainly been no corresponding wealth of reports about the teaching of chemistry, physics or electrical engineering.

The underlying reason would seem to emerge from the fact that the medical sciences, which are part of the general field of biology, have not evolved very far in the hierarchy of science. The physical sciences are well to the fore, and in their present state of development conform far more closely to the pattern that is expected of a well-knit and properly based structure of scientific knowledge. This in turn allows a clear academic separation between the fundamental sciences of physics and chemistry and such applied subjects as mechanical and chemical engineering. Corresponding divisions of interest are quite impracticable on the biological side. As a result, to take an example, the student of zoology or of agriculture may find himself equally concerned either with fundamental or applied science. The same dual, and at times confused, purpose besets the medical departments of a university. Thus, the overwhelming task of a medical school is to train practising doctors. Its next task, but a task not second in importance, is the training of medical scientists and the advancement of medical knowledge. It is this division of purpose which is clearly the background for all educational difficulties in medicine.

Because the two objectives of a medical school are pursued in the same harness, the curriculum for 'applied medicine', if it can so be called, is always immediately affected by changes in fundamental medical knowledge. Unfortunately, however, the curriculum has never been automatically readjusted so that proper weight is given to new advances in relation to old-established knowledge. What has generally happened is that new subjects, as they grew in importance, have been added to the existing syllabus, the structure of which has thus been altered not by changes in its general configuration, but mainly by the process of discrete accretion. Not surprisingly, the medical course has in consequence increased over the past thirty years or so from four to six years. If the same process were to continue, and the strong claims of new interests were admitted, there is no saying how many years would have to be allowed for the training of a doctor in twenty years time.

Here lies the main driving force behind the constant stream of discussions about the reform of the medical curriculum. There is a second to which the British Medical Association Curriculum Committee directs attention—namely, that advances in medical knowledge over the past fifty years have not resulted in a "proportionate improvement" in the standard of medical practice. It is almost a truism that the practice of medicine is more up to date in relation to new biological knowledge than are most industrial and engineering undertakings in relation to advances in the physical sciences. But this is obviously no reason for complacency, and the British Medical Association is right in insisting that, without improvements in the system of education, little can be expected in the quality of our medical graduates. Allowing for the fact that the bulk of the sixty thousand medical men in Britain are in one or other kind of practice, and therefore circumscribed in the expenditure of their energies, it is a startling fact that over the past fifty years or so, most major and fundamental advances in medical science have come from the few hundreds who have kept to the research laboratory. This is all too painfully obvious when one scans the list of Nobel laureates in medicine, or lists of medically qualified men who have been elected to the Royal Society—or to corresponding bodies in other countries. One cannot suppose that more than a fraction of the best minds among medical graduates have dedicated themselves to the laboratory. It is tragic, therefore, to contemplate how circumstances and education have limited the potentialities for advancing medical knowledge which actual practice provides.

In the remedies it suggests, the British Medical Association is at one with the Goodenough Committee and the General Medical Council about such things as the need to eliminate unnecessary detail and specialities from the curriculum; about the desirability of 'integrating' its various parts; and about the fact that the time is ripe to introduce into the curriculum such subjects as psychology and social medicine. It takes an independent line about many matters of more detailed policy. For example, it opposes the Goodenough recommendation that chemistry, physics and general biology for intending medical students could be taught in schools; it holds that anatomy and physiology could be confined to four instead of the five terms recommended in previous reports—although in this recommendation, since its proposed terms are longer, all that is suggested is the curtailment of vacations; it disagrees with the Goodenough Committee that, in general, one can combine good teaching and research abilities in the same individual, and suggests that where the head of a department is a research man, someone else should be made responsible for the teaching.

These and other like matters are, however, questions of detail. The real point is whether the British Medical Association's proposals regarding the direction and integration of the curriculum will achiev the "aim of the medical curriculum". The repor takes the line that "the undergraduate medical cours should be primarily concerned with the training i those basic principles of medicine which are a necessary foundation for all forms of medical practice" This in turn implies that the student should b trained over the whole field of medicine. "Ther should be no clash in outlook", the report reads "between the practitioner and the research worker" since both use the same intellectual methods. An the British Medical Association Committee hold that a proper medical education would have th effect that the medical practitioner would continu to be a student throughout his postgraduat career.

Specialization in education is repeatedly attacked and the report pleads for what is described as th "synoptic view". It argues for a "liberal and general' school education for intending medical students, an opposes early "vocational" concentration on science "general culture", it states, should take the place o "premature narrow specialization in the basi sciences". In its insistence on the need for 'integration', it points out that the many subjects which com into the medical curriculum break the continuity o the student's career. For example, physics, chemistry and biology should be taught in the first year of th medical course "as different aspects of general science" From this would emerge an understanding of th general principles of scientific method, which woul be further laid bare in the syllabuses for anatomy an physiology. Continuity would be better assured b such measures as distributing the teaching of pathology and psychiatry throughout the clinical years, an integration would be helped by ceasing to break u the final examinations into the separate discipline of surgery, medicine, gynæcology, and so on. Th emphasis throughout the report is on re-ordering th curriculum to the end that the patient be seen as whole. General medicine, the Curriculum Committe claims, is the 'linchpin' of the clinical subjects, an should be taught as the basic clinical subject from which the specialities have branched. "It mus remain an integral study of human disease in all it facets, both physical and mental."

A number of these proposals are undoubtedly very sound. But on the other hand, the value of th report is not strengthened by obscure concepts, an in particular by what seems to be an undue allegianc to words such as 'unity', 'whole', 'fundamental principles' and 'general culture'. A synoptic view is clearl useful; but its over-emphasis seems to detract from rather than to enhance its importance. Man, we ar told, must be regarded as a whole, and not as the sun of his component systems; "the sense of the unity o medicine is the special purpose of the teaching o general medicine". Instead of emphasizing excessiv morphological detail, "the general truths of anatomy' should be inculcated. Students, we are also told "must not be allowed to think that laboratory investigations are a substitute for personal observation They should be trained to understand that the purpose of X-rays, pathological reports, and the like, i refute or confirm the practitioner's own findings, and that they must be regarded as servants, not as masters."

It is difficult to avoid feeling that these are mostly platitudes. It is undoubtedly true that a man with a general education is often more interesting and intellectually alert than one without. But as a class, are doctors any less 'cultured' than, say, an equivalent number of men who did not concentrate on science in school and the university ? It is obvious also that a doctor should regard his patient as a whole, and "not as a collection of systems and organs corresponding to the specialities of medicine". But when a patient comes to a doctor, is he really regarded as such ? It is perfectly true, too, that a man should not become the victim of the techniques of observation which he uses. But equally, is it correct to imply that pathological studies or X-ray methods are not just another form of personal observation ?

Above all, it is dangerous to obscure the fact, which is what the Report does, that advances in medical knowledge have come about almost entirely out of increasing specialization, and through the fragmentation of the 'oneness' of medicine. The 'general physician' may be a disappearing species, but it has disappeared over a period in which the health of the people has been progressively improving.

How a deliberate avoidance of educational specialization, beginning at school and continuing through to the end of the 'intern' year spent after medical qualification, can materially improve the quality of medical practice is, therefore, difficult to see. More, not less, specialized scientific training would seem to be wanted if full advantage is to be taken in practice of advances in fundamental medical science. One wonders, therefore, whether the British Medical Association is not attempting the impossible, in so far as the verbal character it imposes on medical education is out of keeping with the trend of developments in medical practice. More and more the general practitioner is taking on the function of a sorting-machine which directs those sick whom it cannot help into specialized avenues for particular treatments. This fact the British Medical Association report clearly recognizes ; but nevertheless it consistently seems to write down the importance of the specialities. The trend cannot be condemned because specialization can be carried too far. That danger will be there whatever form medical education takes. Nor can the trend be stopped, for the simple reason that advances in knowledge, not only in medicine but also in every other field of science or applied science, inevitably mean greater and greater specialization.

If medical education is to undergo the fundamental overhaul which the British Medical Association Committee rightly describes as necessary, it is surely essential to safeguard the education of the specialist, and the specialist approach, as well as that of the general practitioner. The problem is whether the two aims can be satisfied by the same curriculum. The period of medical training is already very long in relation to the years of a doctor's service, and if several more years have to be added to a general medical curriculum for gaining experience in a speciality, the burden of education becomes almost too great. Sooner or later the question will have to be faced whether the approach to reform should not be the opposite of that advocated in most recent reports, including that of the British Medical Association Committee. What may be wanted is the division of the curriculum into specialized 'sectors' that cut right through the clinical and pre-clinical subjects. In such a vertical organisation, the cardiovascular 'sector' or 'department', or the neurological 'department', or the infectious diseases 'department', would embrace their relevant anatomical, physiological, pathological and clinical aspects. The medical student, after an initial year or so in which he became familiar with the language of the subject, and, in general terms, the layout of the body and the nature of its mechanisms, as well as the broad character of the most frequently used techniques of medical education and practice, could move from sector to sector, becoming educated in all aspects of each in the integrated way demanded by the British Medical Association Committee. Teachers would be sufficiently experienced to indicate the interrelations of different sectors, and so to impress the 'wholeness' of medicine in its most useful sense. The time spent in different sectors, and the emphasis of instruction in each, would be varied according to the needs of general practice. But no more time would be spent in all than would be deemed necessary to train a man for the declared purposes of general practice. After his first qualification, the would-be specialist would then concentrate in the sector or sectors of his interest, in an atmosphere where basic science and applied knowledge form an interrelated pattern, and in which either one or the other could become the central interest. A synoptic view over the whole field of medicine seems impossible to attain. A synoptic view within a sector of, say, the problems of digestion and nutrition—all the way from their anatomical to their biochemical aspects—or of the locomotor system, is far more within the bounds of educational possibility. In short, horizontal may have to give way to vertical integration if the medical curriculum is to be materially improved. At the moment the preclinical subjects of anatomy, physiology, and biochemistry supply the normal picture of the whole field that is later split up into the variety of specialities that make up clinical medicine. No amount of horizontal integration or of reference back during the clinical years to the preclinical subjects is likely to achieve as useful an interrelated pattern of education as would a vertical division of interests.

It is in these major matters that the British Medical Association report is least convincing. On the other hand, it contains many useful suggestions that could be immediately applied in medical schools, to the betterment of present educational methods. Very useful, too, is its suggestion that there be formed an "Association of Teachers in Medical Schools" to discuss alternative possibilities for the curriculum—for the British Medical Association Committee has wisely recognized that all proposals are in the nature of plans for experimental action, and that plans must necessarily change with the changing content of medicine itself.

FERN PHYLOGENY

Genera Filicum

The Genera of Ferns. By Dr. Edwin Bingham Copeland. (Annales Cryptogamici et Phytopathologici, Vol. 5.) Pp. xvi + 247 + 10 plates. (Waltham, Mass.: Chronica Botanica Co.; London: Wm. Dawson and Sons, Ltd., 1947.) 6 dollars.

A Revised Classification of Leptosporangiate Ferns

By E. E. Holttum, *J. Linn. Soc. London*, **53**, pp. 123–158 (1947).

BY a curious coincidence two independently compiled reclassifications of the ferns have appeared in print almost simultaneously but from different parts of the world. Both are of very considerable botanical interest, since the phylogeny of ferns is a topic of wider evolutionary significance than the taxonomic context alone might suggest. The phyletic views of the late Prof. F. O. Bower, based largely on anatomical and developmental data, are well known to all morphologists and have for long been the basis of teaching in many universities. The phyletic views of the pure systematist in pteridology have, however, been only imperfectly available. Christensen's phyletic scheme published in 1938 was regarded by its author as only tentative, though unfortunately he did not live to develop it more fully. This scheme has, however, been kept vividly in mind by both the authors under review and both can, in a sense, be read as commentaries on Christensen as on Bower.

The circumstances of composition of the two works are very different. Holttum's explanation of his own is that it was a sequel to the compilation of a Fern Flora of the Malay Peninsula which had been carried out at Singapore between 1942 and 1944, that is, during the Japanese occupation. The step from this to a reclassification of the leptosporangiate ferns seems, therefore, to have been in a sense unpremeditated and the outcome of close acquaintance with the very rich fern vegetation of that country. By being confined to a limited section of the ferns the ground covered is that contained in vol. 3 of Bower's classic work, all of which was, until quite recently, included in the spacious but unnatural family, the Polypodiaceæ.

In Holttum's view the Polypodiaceæ *sens. lat.* should be replaced by five families, namely, Polypodiaceæ *sens. strict.* (including *Polypodium* and *Dipteris*), Grammitidaceæ, Thelypteridaceæ, Dennstædtiaceæ and Adiantaceæ.

To a British botanist the chief interest of these innovations is likely to lie in the third and fourth families. By placing the male fern (*Dryopteris Filix-mas*) as a derivative of *Dennstædtia*, Holttum departs from, and perhaps undermines, one of the central tenets of Bower's phylogeny by which the Dryopteroids are thought to derive from an ancestor with superficial but not marginal sori. Further, by separating the marsh fern (*Thelypteris* not merely into a different genus from the male fer but also into a different family, the Thelypteridacea Holttum endorses and extends a long-considered vie of Christensen's that the genus *Dryopteris sens. la* is polyphyletic. With this latter view, it may b said in passing, some recent cytological work of th reviewer is in complete agreement. An independen statement of somewhat similar views had previousl been published by Ching[1], though this could not hav been known to Holttum at the time.

Copeland's book is a work of greater scope, since i sums up the views of a life-time primarily devoted t the study of ferns and is intended as an authoritativ work of reference, an intention which is on the whol excellently fulfilled. It includes the whole of th ferns and is preceded by a few pages of highly instruc tive historical introduction in which the taxonomi views and practice of the author are briefly discussed Of the 305 genera recognized and described, only si have not been personally accessible to him, whil 33 have been created by him and 69 others revived Some familiar genera have, on the other hand, bee suppressed, and a British botanist will perhaps b surprised to note the submergence of, for example *Scolopendrium* in *Asplenium*. The treatment of th Polypodiaceæ (which is split into twelve families differs in many ways from that of Holttum—a divergence which is easily understandable in the light o Copeland's introduction; but both authors endorse th views of Christensen in his treatment of *Dryopteri* and in other ways. Of the new or revived genera large proportion occur in the Hymenophyllaceæ, th 600-odd species of which are distributed into thirty three genera instead of the two unwieldy groups o *Trichomanes* and *Hymenophyllum*. Pedantic as thi may at first appear it is clearly an essential preliminar to the attainment of clarity on phyletic trends withi this large and interesting group.

The weakest part of the book is the treatment o anatomy. This is clearly not the centre of the author' interest, though he is compelled to make some use o it in his treatment of the Polypodiaceæ. It is perhaps scarcely his fault that comparisons with Bower will be more consciously made by some of his readers than they may have been by himself; but the extreme compression of the allusions to anatomy makes thei inclusion of doubtful value in certain cases. The very well known and complex stem structure of the bracken (*Pteridium*), for example, is merely referred to as a solenostele without further qualification—a degree of simplification which amounts almost to distortion.

On the positive side, a point of unusual interest to a northern reader is the stress which is laid on the southern hemisphere as the putative place of origin for a large proportion of existing fern genera. This view had been strongly impressed on the author by his earlier studies of the Hymenophyllaceæ and other groups, which still have a predominantly southern distribution, and also by his long residence in the Philippines and familiarity with their flora. According to Copeland nine-tenths of all tropical fern genera are of southern origin, and that the Antarctic continent itself may have been the centre of this evolutionary development is an idea which is less familiar to northern botanists than its importance deserves. For this reason alone the book deserves close and critical study by students of vegetation as well as by students of ferns. It should also perhaps be mentioned that the potential value to pollen analysts of the numerous descriptions of fern spores has already been pointed out by Erdtman in a Swedish review; the absence of illustrations may, however, perhaps prove a disadvantage here.

Though it is always possible, in a compilation of this kind, to make suggestions of detailed improvements, these should not, in this case, be regarded as seriously detracting from the sterling value of this book, which as a taxonomic study will remain an indispensable source of reference for many years. Not only the author, but also the publishers are to be congratulated on the production of a compact, convenient, and scholarly piece of work.

I. MANTON

PATHOLOGY OF TUMOURS

Pathology of Tumours

By Prof. R. A. Willis. Pp. xxiii + 992 + 52. (London: Butterworth and Co. (Publishers), Ltd., 1948.) 63*s.* net.

IN all branches of biology where the experimental method, and the co-operation of the chemist and the physicist, are extending our knowledge of living things, it is still essential for the results of morphological inquiry not only to be preserved but also to be reviewed, summarized and restated in the light of contemporary opinions. The descriptive morphologist acquires his knowledge and judgment by long experience, which no interloper, however gifted with modern techniques, can hope to achieve in a short space of time as a subsidiary interest. This is particularly the case with microscopical work, where sound interpretation of the visual image usually requires long experience and training.

Nevertheless, the chemist and physicist who are partners in a modern biological research team will seek at least some acquaintance with the morphological side of the problems they are investigating, and here is a book on tumours which not only pathologists but also all workers in cancer research will find extremely valuable. The author has not provided just another detailed work of reference, confined to the systematic description of the structure of tumours. He begins with an admirable summary, extending over twelve chapters, of the main characteristics of tumour formation, their mode of origin, statistical study of incidence, experimental production in animals, metastases, and the theories of the nature of neoplasia. The second part of the book describes with commendable precision the characteristic features of tumours in specific regions of the human body and includes many case-histories, together with information on comparable tumours in animals.

It is now generally accepted that the successful production of an advanced text-book should be the work of collaborators each responsible for some particular section. So many text-books by a single author are apt to become reproductions in condensed form of the existing literature, enlightened only in those sections where the author has detailed experience. Dr. Willis makes it quite clear that, though he wishes to give a general outline, much of the book is a personal record of his own observations and conclusions. The five hundred illustrations are all from material he has studied personally. Inevitably there are controversies concerning the interpretation of some types of tumour. Where conflict arises with other pathologists, it is refreshing to find the author stating his convictions, avoiding 'non-committal vagueness' and at the same time admitting that his own opinions may have to be modified in the light of further research. There is a vigour and a challenging frankness in his criticism of the work and opinions of others which is perhaps characteristic of the Australian temperament. Where controversies have been tediously prolonged, the more heretical contributors are singled out as "pathologically incorrigible, absurd or deservedly moribund"—expressions which English authors of scientific books and papers unfortunately go out of their way to avoid. The author's opinions, though forcibly stated, are given, however, with reasons that can only be helpful in allowing the reader to distinguish reasonable hypothesis from dogmatic assumption.

As a work of reference the book is well constructed with clear headings to the numerous sub-sections of each chapter. In the references the more important papers are distinguished by a full title with the author's name in block capitals, while the less important papers are indicated in smaller type without title. Dr. Willis wrote this book while holding the Sir William H. Collins chair of comparative pathology in the Royal College of Surgeons of England. He is now director of the Department of Pathology of the Royal Cancer Hospital, London.

E. S. HORNING

FORCES BETWEEN COLLOIDAL PARTICLES

Theory of the Stability of Lyophobic Colloids

The Interaction of Sol Particles having an Electric Double Layer. By E. J. W. Verwey and J. Th. G. Overbeek, with the collaboration of K. van Nes. Pp. xi + 205. (New York and Amsterdam: Elsevier Publishing Co., Inc.; London: Cleaver-Hume Press, Ltd., 1948.) 22*s.* 6*d.* net.

MANY of the classical investigations of colloidal chemistry were concerned with the stability of colloidal solutions of insoluble substances, such as gold, arsenic sulphide, silver halides, etc. The well-known phenomenon of coagulation of these sols by comparatively small concentrations of electrolytes suggested that their stability was connected with their electric charges. A considerable amount of research has been made in the past to discover the magnitude and origin of the electric charge on the particles and the nature of the electrical double layer which exists around them in salt solutions. Although qualitative and semi-quantitative explanations have been given of the phenomenon of coagulation and of the rule of Hardy and Schulze, according to which the ionic concentration required for precipitation diminishes rapidly with the charge of the effective ion, yet a complete and satisfactory theory was still lacking.

The present volume contains the results of theoretical investigations on the problem which were carried out by the authors in the Netherlands during the war years. Some short and incomplete accounts of this work have appeared in various journals, but many of the details are published here for the first time. The book, therefore, has the character of a research monograph. It undoubtedly takes the problem to a more definitive stage and will be studied with care by all who are interested in electrical double layers and with the colloidal state. The publishers are to be commended for making the work available to the English-speaking world in such a complete form.

Briefly, the authors' object was to examine in detail the potential curves for the interaction of particles which are obtained by combining the repulsion which arises from the interaction of their double layers with the London – van der Waals' attraction. Following preliminary work by J. H. de Boer and H. C. Hamaker, it is found that a fairly complete explanation of the coagulation process is obtained from the consideration of the combination of these two types of interaction, using reasonable values of the London attractive constant.

For many readers the most interesting part of the book will be the discussion of long-range attractive forces between particles, which are large compared with atomic dimensions. It is found by summation between all the atoms that the van der Waals' attraction diminishes comparatively slowly over distances comparable with the particle size. As this would give rise to appreciable forces between large particles, a relativity correction is suggested to the London expression, which has the effect of reducing to zero the van der Waals' forces at distances of more than about 10^{-6} cm.

One consequence of the slow decline of the van der Waals' attraction within this range is the fact that at the greater distances the attractive forces may again exceed the repulsive, giving a shallow minimum in the potential energy curves at distances of the order of 10^{-6} cm. It is suggested that this may produce thixotropy with non-spherical particles and may be responsible for the curious phenomenon observed by Bernal and Fankuchen with tobacco mosaic virus, namely, the concentrated aqueous phase in which the rod-shaped protein molecules are arranged in alignment at distances varying from zero to 300 A. or more.

J. A. V. BUTLER

CORROSION OF METALS

An Introduction to Metallic Corrosion

By Dr. Ulick R. Evans. Pp. xxxvi + 211. (London: Edward Arnold and Co., 1948.) 12*s.* 6*d.* net.

THE author's object in writing this book was, in his own words, "to provide an account of Corrosion short enough to be read from start to finish within a reasonable time". Let it be said at once that he has succeeded in his purpose and succeeded admirably. This "Introduction to Metallic Corrosion" provides a general, authoritative and up-to-date survey of the subject, which the serious student should be able to master in the course of a few weeks.

The format and general lay-out of the book resemble that of Dr. Evans' "Metallic Corrosion, Passivity and Protection", but the text is much shorter, amounting roughly to one quarter of that of the major work. This compression has been achieved by the elimination of a considerable amount of less important detail and the rearrangement of the subject-matter in eight chapters as compared with fourteen. The chapter headings provide an apt summary of the contents and illustrate the simple logical classification adopted by the author: they are: film growth; electrochemical corrosion; corrosion by acids and alkalis; influence of environment; effect of stress, strain and structure; prevention of corrosion by soluble inhibitors; prevention of corrosion by protective coverings; and statistical and mathematical treatment. The same methodical arrangement is followed in the sub-headings. For example, those for Chapter 6, "Prevention of Corrosion by Soluble Inhibitors", are: principles of inhibition; cathodic inhibitors; anodic inhibitors; inhibitive water treatment in industry; pickling processes to remove scale and rust; inhibitive pretreatment.

All this renders the book easy to read and to follow. It will also be evident from these headings that, while Dr. Evans dwells with unequalled authority on the whole range of corrosion theory, he is at pains to deal with the practical aspects of the problem and to render the utmost assistance to those who have to grapple with corrosion in the rough and tumble of industry.

One attractive and likable feature of the book is that references to the literature are reduced to a minimum; even so, 165 are needed. These are segregated at the end instead of being given as footnotes. Too much attention can never be paid in any scientific text-book to details such as this, which, however unimportant in themselves, in the aggregate make all the difference between a readable and a tedious book. As an eminent psychologist has written, "It requires considerable effort even to follow one's inclinations with consistency", and any aids such as this to lighten the burden of study are not to be despised.

The book is prefaced by an excellent historical introduction. In this, Dr. Evans covers attractively, in the short compass of some five thousand words, the development of knowledge of the subject from the dawn of history to the present day. Some of the theories, held even by research workers who are still alive, make rather queer reading now; but the general impression gained from Dr. Evans' survey is that of constant progress resulting from the integration and interplay of the ideas of a large number of earnest seekers after truth. Not all of them have been cast in an academic mould, for as Dr. Evans remarks: "Industrial necessity has led to the investigation of many points which the pure scientist would probably have overlooked".

He gives an example to illustrate this. An even better one might be that intuitive reasoning alone could scarcely disclose that the initial cause of the corrosion of steel railway sleepers is damage to the protective tar coating caused by the hob-nailed boots of the men walking up and down the line!

The only feature of the book about which a little diffidence might be expressed is the final chapter on statistical and mathematical treatment. It might have been better to omit this. Statistics is a highly specialized subject, to which Dr. Evans has made important contributions, and it is no aspersion on the mental calibre of many who read this book to suggest that they will find this chapter difficult. Dr. Evans has evidently considered this point and was, no doubt, influenced in his decision by the fact that the subject-matter had not previously been published as a connected whole.

In brief, this is an attractive, well-written and well-produced book which will fulfil the purpose for which it is intended, and will undoubtedly appeal to a much wider circle of readers than the more comprehensive "Metallic Corrosion, Passivity and Protection". It is fully worthy of the author's high reputation.

J. C. HUDSON

THE ATOMIC ENERGY RESEARCH ESTABLISHMENT, HARWELL

THE Atomic Energy Research Establishment was founded by a decision of the Government in ovember, 1945, and Prof. J. D. (now Sir John) ockcroft was appointed director in January, 1946. n order to provide a nucleus of accommodation and prepared site, the permanent R.A.F. aerodrome of arwell was allocated to the Establishment and uilding work began there in April, 1946. Harwell as chosen because of its convenient geographical cation, combining reasonable access to London ith nearness to a large university (Oxford), which as considered to be important so that staff should ve good opportunities for discussion with university olleagues.

A nucleus of experienced staff was available in 46, some of whom had worked in the United States tomic Energy Project at Los Alamos and Berkeley, hile others had helped to build the Atomic Energy lant at Chalk River in Canada. These were joined y experimental electronics staff working at the elecommunications Research Establishment in Malern, and by a few senior members of universities. his nucleus has been added to by the recruitment of nior staff, and there are at present Divisions of heoretical Physics, Nuclear Physics, General Physs, Chemistry, Chemical Engineering, Metallurgy, nd Health, each of the size of a large university search school.

The Establishment has very close links with the niversities and industry. Many senior members of e project after the War returned to take charge f university departments; these scientific workers e now consultants to Harwell and some of them rve on the Technical Committee which advises the epartment of Atomic Energy. In addition, many the technological problems of the Establishment e solved by collaboration with industry and with boratories of Government departments and research ssociations.

The purpose of the Establishment is to carry out ndamental research and development in atomic ergy. It is responsible also for providing scientific nd technical information to the Controller of Production, Atomic Energy (Lord Portal) and his gineering organisation at Risley, which is preparing e design for the plutonium production plant which being built near Sellafield in Cumberland.

Pile Programme

The first requirement for an atomic energy proamme of this nature was to build piles, and the st pile, GLEEP (graphite low energy experimental le), was completed in August, 1947. It is a slow utron graphite moderated reactor developing 00 kW. of nuclear energy. The simplest possible sign was chosen so that early experience could be ined in pile operation, and, in fact, the time taken om beginning constructional work to the start-up the pile was only just over a year.

It has a concrete shield, five feet thick, and the aphite blocks and natural uranium rods are built within the shield roughly in the form of a cylinder ing on its side. The power-level at which the pile operating is measured by means of boron trioride chambers sunk into the pile, and the current the chambers suitably amplified is displayed in e control room on a dial calibrated directly in kilowatts. This information is also used to maintain the power of the pile at a constant level by controlling the position of neutron-absorbing cadmium 'control rods', hanging vertically in the pile. A second set of 'shut-off rods' is available to shut down the pile.

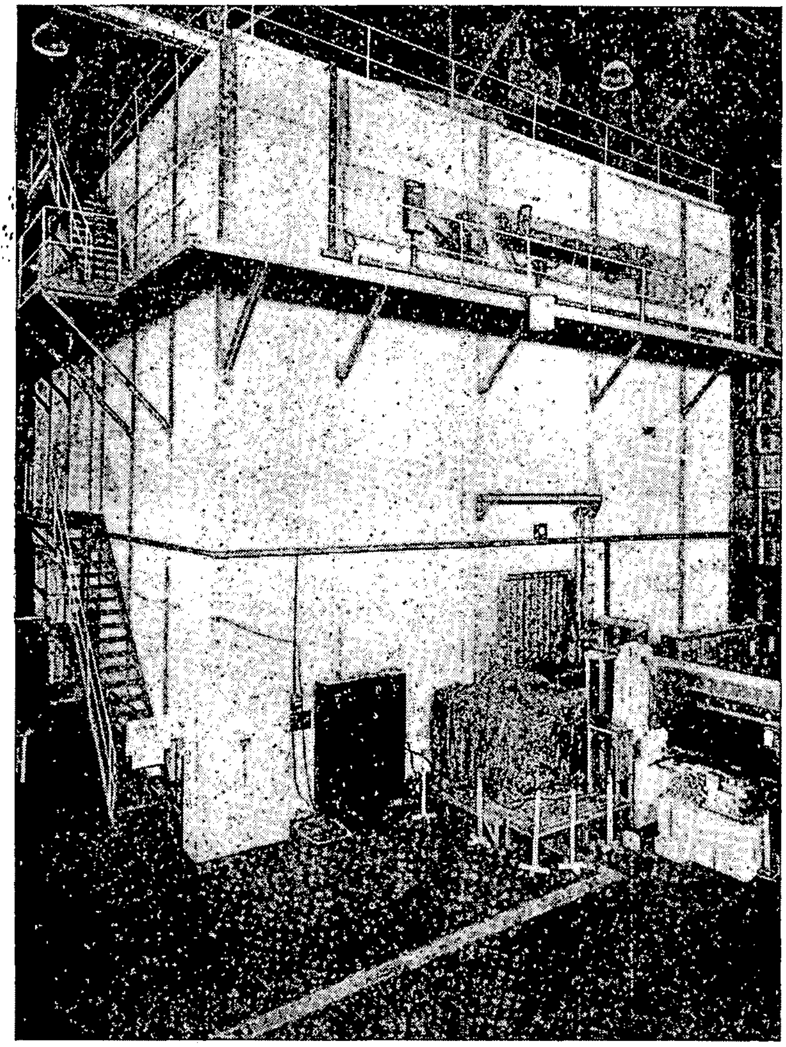
GLEEP is being used for measurement of the properties of atomic nuclei, for testing the nuclear properties of materials used in the construction of piles and for the production of radioactive isotopes.

The second pile, BEPO (British experimental pile), started up at 3 p.m. on July 3, 1948. Although not much larger physically than GLEEP, it is a much more complicated engineering structure and is designed to develop 6,000 kW. of nuclear energy. The heat is removed by an airstream which is drawn through the channels in which the uranium rods lie, and exhausted through a 200-ft. chimney stack. This pile will be used for studying the effects of irradiation on the structural and physical properties of materials which will be used in future piles, and the much higher neutron flux available makes possible a correspondingly wider range of experiments than in GLEEP. BEPO will also be the main source of radioactive isotopes for Great Britain, and it is expected that this work will be transferred from GLEEP to BEPO towards the end of this year, thus freeing GLEEP for full-time experimental work.

In preparation for building these two piles, it has been necessary to develop the production of pure graphite both in Canada and in Great Britain, and also to produce pure uranium metal and fabricate from it the aluminium-encased uranium rods which are used in the piles. This work has involved a large development programme, all of which has been undertaken outside the Establishment, both by industry and other Government establishments.

After the operation of piles, the next stage in a pile programme is the extraction of plutonium from the irradiated uranium metal, and information on the extraction process will be required for the Sellafield plant. The chemical problems involved in the separation of plutonium from the unused uranium and the highly radioactive fission products are among the most difficult in the atomic energy programme, and for this and other radiochemical work a new laboratory is being built at Harwell. This new radiochemical laboratory is a large two-story building, consisting of a central administrative block, connected by air locks and changing rooms to two wings. The wings contain a number of self-contained laboratory suites, each fitted with lead-lined chambers where all radioactive work will be done. A very large air flow is required through the chambers, equivalent at maximum rate to 120 air changes per minute in the laboratories, and this has led to the provision of an exceptionally large ventilation system, the air ducts for which, together with other services, occupy the whole upper floor of the building. Until this building is complete, temporary laboratories for the work have been provided in one of the original buildings.

Buildings are also being erected for chemical engineers, who will follow up the work of the research chemists with semi-scale plant. The chemical engineering programme includes the study of methods of extraction of uranium from the many kinds of low-grade ores in which it occurs.



General view of GLEEP

Industrial Applications of Nuclear Power

The Atomic Energy Research Establishment is working on the problem of the application of nuclear power to industrial purposes. A very small beginning will be to extract from the cooling air stream some of the heat developed by BEPO and to use it for space heating. A heat exchanger for this purpose is being installed.

The design of natural uranium piles in which power could be generated as a by-product at a moderate efficiency is being investigated in detail. This investigation is not complete; but it would appear that the construction of such piles is likely to be technically feasible. They would not, however, be worth while economically since such piles only burn up a very small proportion of the uranium. They would only be worth while as a first step to gain experience.

If nuclear power is to become important in the world, four major problems have to be solved. First, the so-called breeding problem must be solved—uranium 235, the only naturally occurring, or 'primary', nuclear fuel must be made to breed 'secondary' fuel from more abundant materials: either plutonium from uranium 238 or U233 from thorium. Second, materials must be found which
will stand high temperatu
and be suitable for use in p
construction. Third, the che
ical extraction problem mu
be solved—the fissile mater
produced must be separat
economically from the unus
uranium or thorium and t
intensely radioactive fission p
ducts. Fourth, a method
disposal must be found f
the large amount of unwant
radioactive material which wou
be produced by power statio
operating on nuclear fuel.

These problems are difficu
and their solution is going
take time. For this reason,
serious person working in t
field believes that nuclear ener
will make any contribution
world power during the ne
decade. At present, work
entirely in the theoretical a
laboratory stages; but it
probable that a number of pi
plants will be built to allow
these problems to be invest
ated. Until this is done
accurate assessment of the pos
bilities for the future can
made.

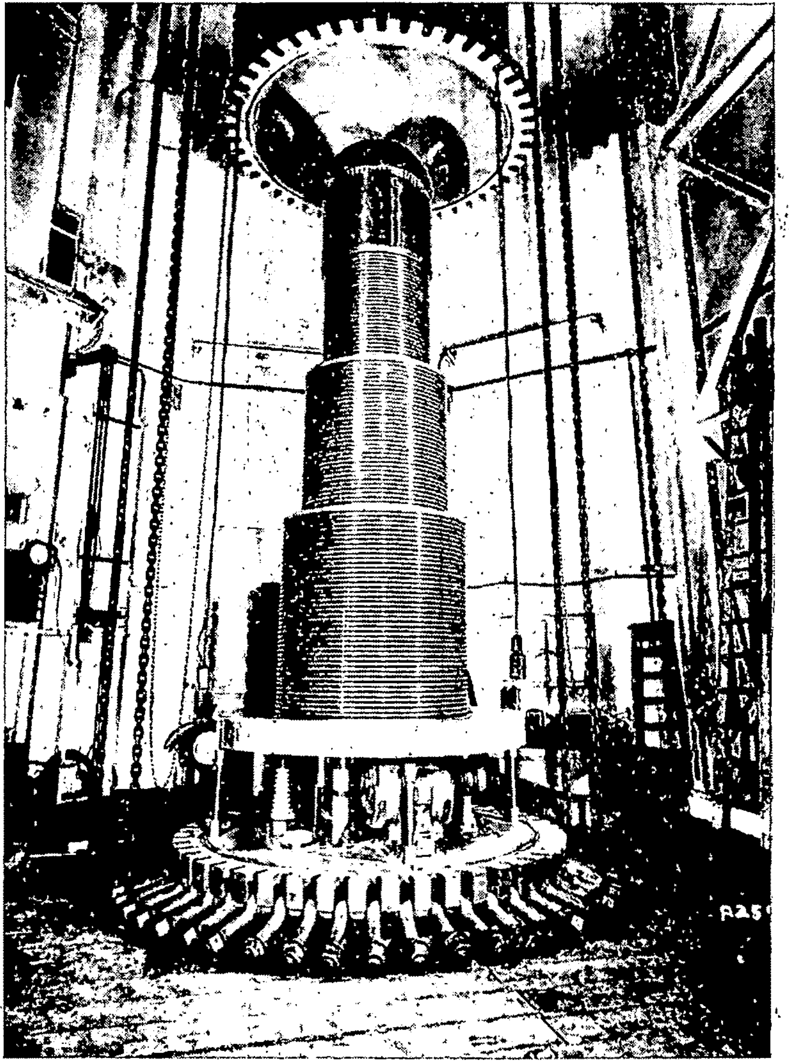
Nuclear Physics

For fundamental research
nuclear physics the Establis
ment is being equipped,
addition to the two piles, wi
several particle-accelerating m
chines.

A frequency-modulated cyc
tron with 110-in. diameter p
pieces is under construction whi
will produce particles with
maximum energy of about 200 MeV.: it will
completed about the end of this year. This machi
will enable the nuclei of most atoms to be brok
up, and will be used to produce new types of nuc
which cannot be produced in the piles.

For the production of monokinetic beams of low
energy particles, a 5-million volt Van de Gra
generator has been built. The design is similar
that of a machine recently completed by Prof. V
de Graaff at the Massachusetts Institute of Tec
nology, and close contact has been maintain
between the Atomic Energy Research Establishme
and the Massachusetts Institute of Technology tea
The design voltage has been obtained without t
accelerating tube in position, and tests are in progr
with accelerating tubes. A 2-MV. machine for wo
in radiation chemistry has been built and is bei
tested by the manufacturer.

In addition to machines for work at Harwell, t
Establishment is assisting universities and t
Medical Research Council by carrying out, on beh
of the Department of Scientific and Industr
Research, development of high-energy particle acc
erators for use in universities and medical depa
ments. A group working at the Telecommunicatio
Research Establishment in Malvern is directing t



Van de Graaff high-voltage generator

velopment of synchrotrons, in-
ding two 30-MeV. machines
r the Medical Research Council,
140-MeV. machine for the
iversity of Oxford and a
0-MeV. machine for the Univ-
sity of Glasgow. It is also
veloping the design of linear
celerators and recently com-
eted a 4-MeV. machine which
now in great demand for
perimental work in nuclear
ysics and radiation chemistry.
Apart from accelerating ma-
ines, a beta spectrometer has
en completed with provision
automatic recording, and
all groups are working on the
sign of neutron spectrometers
d other problems.

The Isotope Programme

It has already been announced
at GLEEP has been used for
e production of radioactive
topes since September 1947.
e rate of production of samples
s increased steadily and is
w about 150 per month.
together more than eight hun-
ed deliveries have been made,
ostly to English universities
d hospitals and to workers
the Establishment, but in-
ding a few to European
untries, and one air delivery
South Africa.
It is expected that BEPO
ll take over the production
radio-isotopes towards the
d of 1948. It will then be
e main source of radio-isotopes
r Great Britain, and will make
possible to extend the supply
countries in the British
mmonwealth and Europe. The higher neutron flux
ailable will allow the preparation of a much wider
nge of materials, and of higher activity samples.
It is intended that the chemical processing and
livery of samples, except those with very short
lf-lives, will be undertaken by the Radio-Chemical
ntre at Amersham, and arrangements have been
ade for the Chemical Research Laboratory to
epare complicated organic molecules containing
dio-carbon, when these are required.
In addition to radio-isotopes, the Establishment
ll produce separated stable isotopes of many ele-
ents. Research groups are working on the separation
stable isotopes by several methods, including
ermal diffusion, fractional distillation and chemical
change. A thermal diffusion plant for the prepara-
on of enriched oxygen 18 is being built, which
ould give by autumn 1948 a yield of 1/7 gm. of
ygen 18 per week, at a concentration of 20 per
nt. A 34-ft. fractional distillation column, working
th liquid carbon monoxide, will be complete in a
w months time, and should give a yield of 0·3 gm./
y of carbon 13 by the end of the year. A small-
ale electro-magnetic separator has been built for
her elements, and a much larger instrument, capable of separating any elements, is being erected. Several mass spectrometers are available for assaying samples, and some development work on the design of these instruments is being undertaken.

Electronics

An atomic energy project requires a great variety of electronic instruments, for example, for pile control, radiochemistry, experiments in nuclear physics and health monitoring. A considerable section of the staff is engaged in designing and developing these instruments. In general, the design is carried to a stage where it can be taken over for production by industry, and the Establishment takes the initiative in finding the requirements of university and medical users, so that their needs also can be met in both the design and production stages.

Health

In view of the possible hazards from radiation and radioactive dusts, very stringent precautions are taken at the Establishment, and the health of all workers is the responsibility of a Medical Division. Everybody is given a thorough medical examination on joining the Establishment, and this is repeated periodically. Workers exposed to radiation have their blood examined from time to time to see whether any change occurs in the number of cells, due to exposure to radiation. Safety measures taken have been such, however, that no over-exposure has occurred and there has been no single case of any harmful effects due to radiation.

Arrangements for the monitoring of scientific workers and their laboratories for radioactivity are the responsibility of a Health Physics Group. Staff exposed to radiation carry a photographic film to record the total dosage taken each week, and those working in very active areas carry pocket condenser chambers from which they can see at any time the amount of radiation to which they have been exposed since the chamber was charged. In addition, fixed instruments are placed in the pile buildings, active chemistry laboratories and grounds to provide a continuous record of radiation. Portable instruments are used to make measurements during any operation such as withdrawing materials from a pile. As a result of all these precautions the actual exposure of staff to radiation is well below the levels which have been recommended by the Medical Research Council. The Health Physics Group is also responsible for monitoring the effluent water from the Establishment and seeing that it complies with the rigid specifications laid down by the Medical Research Council.

SOME NEW RHEOLOGICAL PHENOMENA AND THEIR SIGNIFICANCE FOR THE CONSTITUTION OF MATERIALS

By S. M. FREEMAN
AND
K. WEISSENBERG*
British Cotton Industry Research Association

THE materials studied in rheology are of varied constitution, with intricate patterns of constituent components of visible, colloidal, molecular, atomic and sub-atomic sizes. The patterns range from a *coarse-grained* type in which a discontinuous structure is apparent, to a *fine-grained* one which appears homogeneous and continuous to the eye and even to the microscope; the former type is represented by biological tissues, textile materials, natural and synthetic sponges, foams, powders, timber, cement, etc., and the latter by gases, amorphous liquids and solids, single crystals, etc. In the engineering constructions of Nature and man, widespread use is made of coarse- and fine-grained materials, and this invites an investigation into their mechanical properties as exhibited in changes of volume and form, and into the relation between these properties and the constitution of the materials.

In the present article we shall discuss experiments in which we use both types of material, the coarse-grained ones being particularly valuable here because they can be made to give combinations of mechanical properties suited to the purpose in hand and not easily available in the fine-grained types. Moreover, one can easily vary the constitution of coarse-grained material by physical means an observe macroscopically how the mechanical pro erties depend on the constitution. As an exampl consider coarse-grained sponges of rubber or rubbe like substances. The sponges can be made to displa large elastic recoveries of strains for changes of bot volume and form, a combination not found in fin grained materials. Moreover, the sponges can made in various structural designs, including extremes of an *open* structure with intercommun cating holes, and a *closed* one with isolated hole and also covering a wide range of mixed structur in which the holes may be filled with air or visco or visco-elastic liquids. Another example is provid by the coarse-grained assemblies of fibres, rangi from single hairs to textile fabrics, and yet anoth by powders, etc. We select from the materia of all types samples of a size sufficiently large allow a determination of the mechanical properti in terms of a *continuum theory*, the coarse- and fin grained structures alike being averaged out in continua over regions of macroscopic, microscop or submicroscopic dimensions. For the coars grained materials we can then observe simulta eously the mechanical properties as defined by t continuum theory, and the constitution as reveale by the structural pattern of the components macroscopic size, and thus have a means correlating one with the other. For the fine-graine materials we can observe the mechanical properti as before, and elucidate by analogy the correlati with the hidden constitution on a microscopic a submicroscopic scale.

For ease of reference we shall introduce a nome clature suited to distinguish between different kin of response to mechanical actions. We have exa ined all the materials first in their natural state, wh they are at rest and free from externally appli forces, and we use the term 'isotropic' to indica that the material in its natural state displays f spherical symmetry in response to actions along t various directions in space; the term 'compressib is used to indicate appreciable changes in volu within the range of actions considered; and t term 'shear elastic' to denote in that range appreciable amount of shear strain recovery under sudden release of all external forces. By contra we use the term 'anisotropic' for a deviation fr spherical symmetry, and the terms 'incompressib and 'shear inelastic' when the changes of volume a of shear strain recovery respectively are inapprecia small.

Continuum Theory of the Elasticity of Volu and Form

In the discussion of a continuum theory of t elasticity of volume and form, we shall restrict o selves to materials which are isotropic in their natu state, since the theory appears for these materials its simplest form.

We consider here a differentially small portion an elastic material. Under an applied load of exter forces, the portion will pass from its natural state some static state of equilibrium, shortly referred as the 'loaded state', and will appear there as a cu with edges of unit length. In transit from the natu state the cube will have acquired in the loaded sta a certain *strain*, according to the changes in volu and form, and a certain *stress*, according to t external forces which appear here as traction forces per unit area acting across the faces of the cube. We can then resolve the strain and the stress into components tangential and normal to three adjacent faces of the cube, arrange these components into two square matrices, and define quantities, termed scalar invariants, which remain unaltered under all changes of orientation of the edges and faces of the cube to which the matrices refer. For a given matrix one can express any arbitrarily considered scalar invariant as a function of three, and only three, mutually independent ones, which are distinguished as the first, second and third in accordance with their degrees in the matrix components, and defined respectively as the sum of the terms in the principal diagonal, the sum of the minors of these terms, and the determinant of the matrix. It is then the task of a continuum theory of elasticity to introduce the laws which relate the matrices of stress and strain to one another.

---

* Present address: British Rayon Research Association, Bridgewater House, Whitworth Street, Manchester 1.

The classical continuum theory considers only infinitesimally small strains, and assumes for these the validity of Hooke's law. When we apply this law to isotropic materials, we find that the changes of volume must be independent of the tangential components of stress, and the changes of form must be independent of the normal components. Moreover, the law postulates here that the changes of volume are linearly proportional to the mean *isotropic pressure*, calculated as the arithmetical mean of the normal components of stress, and the changes of form linearly proportional to the *deviatory stress*, calculated by subtracting the mean isotropic pressure from the total stress present; the proportionality factors are known as elasticity moduli of volume and of form respectively.

The general continuum theory[3] by contrast considers strains of any amount, small or large, and makes no assumption as to the validity of Hooke's law. We find then for isotropic materials that the changes of volume and of form become interdependent in the sense that the tangential components of stress make some contribution to the changes of volume, and the normal components of stress make a contribution to the changes of form. Lord Kelvin[2] foreshadowed such a possibility in the following words: "It is possible that a shearing stress may produce, in a truly isotropic solid, condensation or dilatation in proportion to the square of its value". We find a general law, according to which the changes in volume can always be expressed as a function of the three scalar invariants of the matrix which represents the stress. It will be noted that the first invariant of stress is linear, contains only the normal components of stress, and is equal to an isotropic pressure multiplied by the factor three, while the second and third invariants are of degrees higher than one and contain normal and tangential components. For a first-order approximation, such as may be allowed for infinitesimally small strain, we neglect terms of higher degrees in the stress components and so find in accordance with Hooke's law that the changes in volume will depend only on the isotropic pressure. When, however, the strains are of appreciable amount, we must take terms of all degrees into account, and we then find non-Hookean terms in the changes of volume which make these changes disproportional to the isotropic pressure, and dependent on both the shear and normal components of stress. In particular, it is to be expected that under large amounts of strain changes of volume may occur even though the first invariant of stress, and the isotropic pressure, are equal to zero, and further, that even paradoxical effects may be expected in which, for example, the volume is decreased while the isotropic pressure acting across the face of a differential cube is a pull. Such a paradox is resolved when one regards the three different invariants as a result of three different ways of forming mean values by averaging over the full solid angle of directions in space. The first invariant corresponds to a mean of the first powers, that is, to a simple arithmetical mean, while the second and third invariants correspond to means of second and third degrees respectively. In the Hookean postulate it is assumed that, for changes of volume, only the arithmetical mean of the traction forces is of importance, while in the general theory means of higher degrees are also admitted.

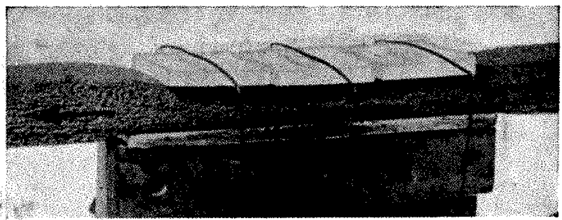


Fig 1

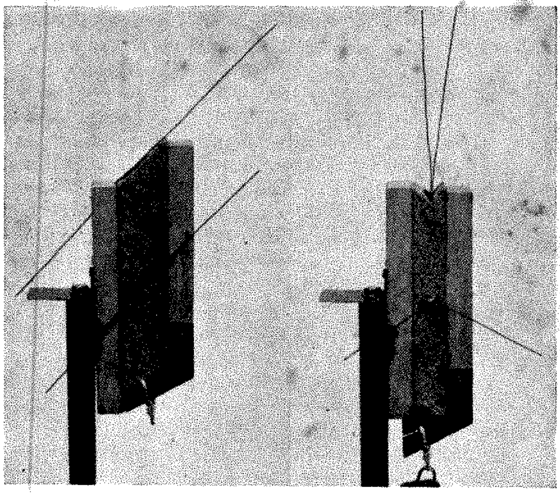

(a) (b)

Fig. 2

To demonstrate experimentally the whole range of effects which are expected in accordance with the general laws we need isotropic materials capable of large elastic recoveries of strain, both in volume and in form. Such materials are available only in a coarse-grained type, and are here provided by the air-filled sponges of rubber with open and closed structures. These sponges show in a striking manner the non-Hookean terms in the changes of volume.

Fig. 1 refers to a sample of sponge rubber which is pulled lengthwise by a 7-lb. weight (indicated by arrows) and simultaneously compressed in height by three blocks of 'Perspex', each loaded by a pair of $\frac{1}{2}$-lb. weights. Attention should be focused on that part of the rubber sponge which lies beneath the middle block, since the blocks on either side are used only as guards intended to secure a nearer approach to homogeneity in the middle. A measurement of the dimensions of the sample reveals that the volume

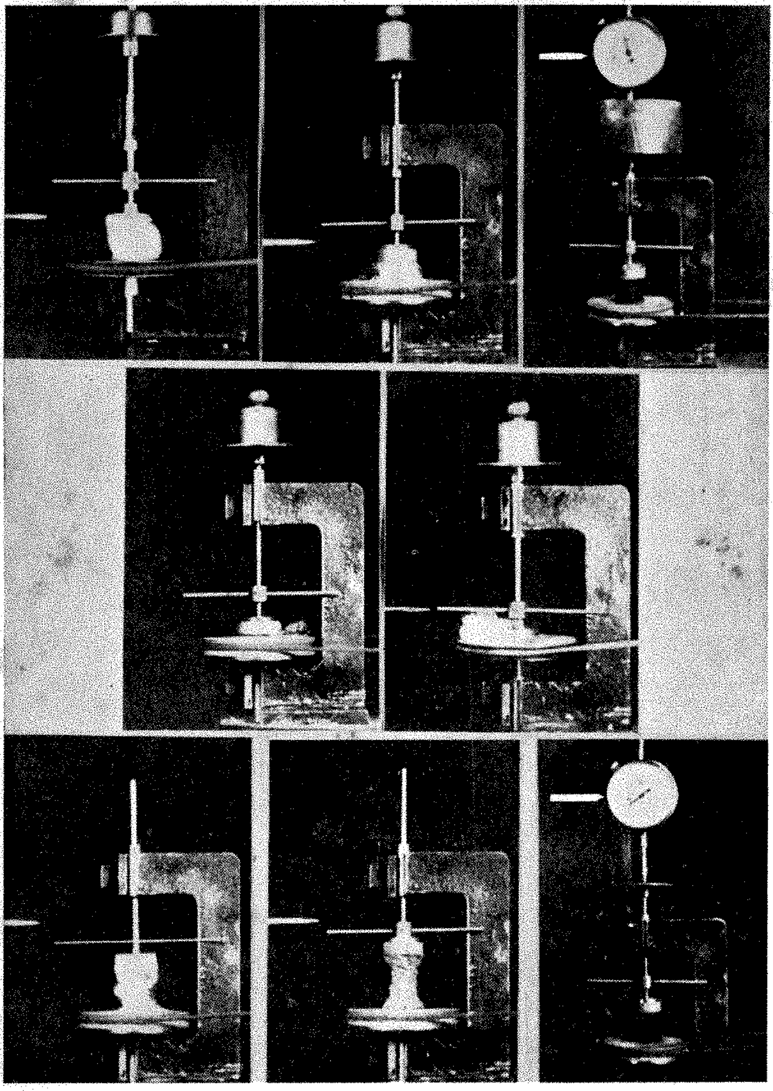

Fig. 3

of the middle part is reduced by about 40 per cent compared with the unstrained state, as the conspicuous decrease in height completely overshadows the changes in the dimensions in length and width. At the same time, the mean isotropic pressure is distinctly in the sense of a pull, since per unit area the lengthwise pulling force is about twenty times as great as the vertical compressive force.

Fig. 2 (*a*) and (*b*) refers to an open sponge rubber cemented between two blocks of wood, the unstrained state being shown on the left (*a*), while on the right (*b*) is the strained state reached when a weight is hung on a bracket fixed to one of the wood blocks. It can be seen that in the strained state the sponge has contracted in all three dimensions, the ends and sides being sucked in, as revealed by the motions of the attached wires, and the thickness being reduced as shown by the decrease in the distance between the wood blocks. In this experiment volume reductions exceeding 40 per cent have been noted, while an examination of the stresses (which is difficult on account of the fact that the stress is heterogeneously distributed in the sponge) shows a mean isotropic pressure in the sense of a pull.

Similar results have been obtained in experiments on samples of sponge rubber of the closed type, and this means that the volume effects shown in Figs. 1 and 2 are by no means restricted to materials with structures in which the changes of volume can occur through an expulsion of the air from the holes in the structure.

Constitution of Matter

In flow experiments on coarse-grained materials, one may observe on a macroscopic scale both the structure and the particular kind of mechanical behaviour displayed, and then correlate one with the other. Such a correlation is difficult to establish for fine-grained materials, since the structure cannot be observed macroscopically. If, however, similarities in behaviour are found between two materials, one visibly discontinuous and the other apparently continuous, the structure which is seen in one provides a possible model (at least) for that which is unseen in the other. (Such an idea appears frequently in scientific literature. H. Mark and F. Eirich used suspensions of elongated particles in liquids to simulate colloidal solution of long-chain molecules, and Sir Lawrence Bragg used groups of soap bubbles to throw light on the sub-visible details of the crystalline structure of metals.) In this way a bridge can be built between the structural and the continuum theories, and an approach made towards finding for the fine-grained materials a correlation between structure and the rheological behaviour.

Preliminary experiments were made to reveal the correspondence in rheological behaviour for the various types of materials here considered.

We first tested the shear elasticity by applying a shearing action and observing the recovery of shear strain under a sudden release of all external forces, so distinguishing between shear-inelastic and shear-elastic materials. We thus collected into the shear-inelastic class some types of fine- and some of coarse-grained materials, the former including optically clear brittle solids, Newtonian liquids, and gases, and the latter dry powders such as chalk, glass, etc. Similarly, we were able to group into the shear-elastic class certain fine-grained types, including colloidal solutions of gelatine, cellulose, rubber, saponified oils, etc., and certain coarse-grained types including the rubber sponges (open and closed) and a large variety of assemblies of fibrous constituents, with the fibres occurring as single hairs or yarns, curled up or stretched out, arranged in a random or orderly manner, varying in length from a millimetre to several metres and composed of wool, cotton, rayon, silk, metal, asbestos, etc.

We then tested the compressibility of the materials and drew a dividing line between the materials termed incompressible and those termed compressible. To a first approximation the dividing line can be drawn so that we find on the side of the incompressible materials fine- and coarse-grained types which are wholly in the condensed states, that is, solid, liquid or intermediate, while on the side of the compressible materials we find the types which are wholly or partly in gaseous states. The division is particularly interesting for the shear-elastic class, in which we find that the types of fine-grained materials considered, namely, the colloidal solutions, are wholly condensed and thus incompressible, whereas the coarse-grained types of rubber sponges and fibrous assemblies contain gases (air) and are accordingly compressible.

On the basis of the classification given above, we can predict in a qualitative way the behaviour under various conditions of the materials within one class and division. We shall illustrate these predictions by describing for the coarse- and the fine-grained materials of the same class experiments under conditions chosen first so that all the materials behave alike because of their class resemblance in shear elasticity[1,3], and secondly, so that they behave differently on account of the additional complications caused by the differences in compressibility.

In the experiments illustrated in Fig. 3, an upright cylindrical specimen of the material considered was subjected to torsion between two parallel disks, the lower one fixed in height but capable of rotation, and the upper one free to move up and down but prevented from rotating. This was achieved by mounting the lower disk on top of a pulley, and securing the upper disk to a stem which slides in a sleeve and carries a crossbar which is checked by the supporting frame. The cylindrical wall of the specimen was left open to the atmosphere. Experiments were performed with various materials including liquids, fibrous assemblies and rubber sponges, but only the shear-elastic materials are shown since the others produce effects of a merely trivial kind. To apply the torsion it is necessary that the material should stick to the disk. For the liquid no special measures are required, but for the fibres it is necessary to face the disks with glass paper, and the sponges must be secured by cementing (thanks are due to Messrs. Dunlop Rubber Co., Expanded Rubber Co., and B.B. Chemical Co., who supplied us with a wide range of sponges, expanded rubbers and adhesives). The photographs show the results of the application of torsion. The pointer on the left-hand side of a picture indicates the original height of the top disk by pointing to the original position either of the crossbar, or of the hand of the dial-gauge.

The first row shows three pictures referring respectively to a fine-grained material, namely, a colloidal solution, and to two coarse-grained materials, namely, a fibrous assembly and a sponge with a closed structure. The materials are subjected to torsion while at the same time they are compressed by a weight. Under these conditions the materials develop stresses which drive them inwards to such an extent as to push the top disk upwards against the action of the weight. The amount by which the top disk rises differs in the three cases, being greatest for the colloidal solution, less for the fibrous assembly and so small for the sponge as to require a dial gauge to reveal it. For the colloidal solution, the torsional motion has to be maintained at constant velocity during the exposure, as otherwise the liquid would lose its stress and run out of the gap. (It is particularly striking that the stresses hold this material in place despite the opposing influence of gravitational and centrifugal forces.) On the other hand, the sponge is a solid which is subjected to a static torsion. The fibrous assembly can be treated as a solid or a liquid, and the torsion applied statically or dynamically.

The second row of pictures shows a visco-elastic liquid and a fibrous assembly. The arrangements are similar to those used for the previous experiments, except that now the speeds and other conditions of the experiment are so chosen that a disturbance occurs in the form of an eddy which rolls the material up and then ejects it from the gap. The photographs were taken at the instant of ejection. No exact theory has yet been developed to account fully for this phenomenon, which occurs exceptionally in liquids but commonly in the fibrous assemblies; it was first observed by K. Weissenberg and R. J. Russell on some specially prepared visco-elastic liquids.

All the photographs so far discussed show the similarity between the coarse- and fine-grained materials. By contrast, the third row shows the additional complication produced in the coarse-grained materials because of their compressibility. The specimens are a fibrous assembly, an open sponge and a closed sponge, in all cases cemented to the disk and treated as solids. A statical torsion has been applied; but in this case without weighing down the top plate. All the materials are again drawn inwards, but the upper disk is pulled down, that is, in the opposite sense to that shown before. It is evident that the materials have been reduced in volume by the waisting and reduction in height.

From the experimental observations cited, it may be concluded that a wide range of structures of cellular or fibrous type provide possible models for the hidden molecular structure of the apparently continuous colloidal solutions in the shear-elastic class. Such models would be insufficiently resistant to changes in volume, and it would be necessary to provide for the missing resistance by appropriate assumptions.

Thanks are due to the director of the Shirley Institute for giving us the opportunity to carry out this work and permission to publish it. We are indebted to Mr. C. Bradley and Miss J. Gallagher for the photographs accompanying this article.

BRITISH ASSOCIATION

BRIGHTON MEETING

THE programme for the 110th Annual Meeting of the British Association for the Advancement of Science has now been published. The meeting will be held in Brighton during September 8–15, under the presidency of Sir Henry Tizard, who will deliver an address on "The Passing World" in which he will review some of the outstanding features of the progress of science and technology in Great Britain from the close of a period of stagnation towards the end of the nineteenth century.

The meeting will be held, as usual, in thirteen concurrent sections with a number of joint sessions, and the programme also includes evening discourses and a session of the Division for Social and International Relations of Science, at which Dr. Julian Huxley and others from Unesco will discuss "Science Across the Frontiers".

The sectional programmes contain a wide variety of topics, ranging from cosmic magnetism to the effects of the cinema on young people. The objects of the annual meetings of the Association being to provide opportunities for men of science to meet each other and discuss their work in the setting of science as a whole, to allow men of science and laymen to meet each other, and to increase the public understanding of science, the programme includes both specialist and general topics (nearly three hundred speakers).

Among the former are sessions on recent advances in the crystalline state, opened by Sir Lawrence Bragg, geology and air photography, functional morphology (including an address by Prof. H. Graham Cannon), the denudation of the weald, applicable mathematics, the case for and against the metric system, transmission of effects from the endings of nerve fibres (opened by Sir Henry Dale), recent advances in colour vision (including an address by Prof. H. Hartridge), to mention only a few.

The more general topics include industrial applications of electronic devices (with exhibition), new metals in industry, new building materials, problems of Colonial development, movements of population, fuel economy with special reference to the heat pump, human blood groups, problems of old age. Various aspects of food and nutrition will be discussed at several sessions arranged by the Sections of Zoology, Economics, Physiology, Agriculture and Chemistry, and the programme also includes discussions and talks on science in industry as arranged by no fewer than seven sections.

Arrangements have been made for sixty excursions and a number of social engagements, and the members will be entertained at a civic reception in the buildings on the Royal Pavilion Estate.

Further details of the meeting may be obtained from the Secretary of the British Association, Burlington House, London, W.1 (Regent 2019). There is no closing date for registration, and hotel accommodation is still available in Brighton.

THE SWEDISH DEEP-SEA EXPEDITION

By Prof. HANS PETTERSSON
Göteborg

AN account has already been given of the first part of the cruise of the *Albatross* (see *Nature*, October 25, 1947, p. 559). On August 27, 1947, the *Albatross* started from Balboa on its cruise across the Pacific Ocean, and five months later terminated it in the idyllic harbour of Ternate, visited by the *Challenger* Expedition seventy-three years earlier. The course led first to the Galapagos Islands, where the upwelling cold water and the deposits beneath it were studied; then along a west-north-west direction until the eighteenth parallel was reached, from there turning south for Nukuhiva and for Tahiti. Between Tapeete and Honolulu the course of the *Challenger* was followed, although to the opposite direction, several of its stations being repeated under way. From Honolulu the course lay to the south-south-west and, after crossing the equator for a fourth time, we steered west-north-west, finally reaching the great deeps south-east of Mindanao.

Our four first crossings of the counter-equatorial current were used for a close study of its hydrography by frequent deep series, intercalated by bathythermograph shots through the uppermost 140 metres. Interesting results are shown by our diagrams, as the signs of upwelling and descending water in the regions of divergence and convergence respectively in the surface. A distinct oxygen minimum extended from a few hundred metres downwards for 800 m. or more. Clouds of suspended particles studied by the Tyndall method were met with also at great depths.

The ruggedness of the sea bottom revealed by our echograms often proved an obstacle to coring operations, as were also the not infrequent encounters with hard bottom (lava beds) at great depths, sometimes leading to partial or total loss of the steel coring tubes. Nevertheless, fifty-seven cores, varying in length from a few metres to fifteen metres, were raised from depths between 2,000 and nearly 8,000 m., their total length approaching 500 metres. Many of them, especially those taken near the equator, showed a pronounced stratification indicating changes of surface conditions affecting the distribution of plankton organisms. A special feature on our echograms near the regions of divergence at the surface were diffusely reflecting layers in a depth of 100–250 metres, presumably fish shoals or masses of other pelagic organisms. Attempts to sample these reflecting layers failed for lack of suitable gear.

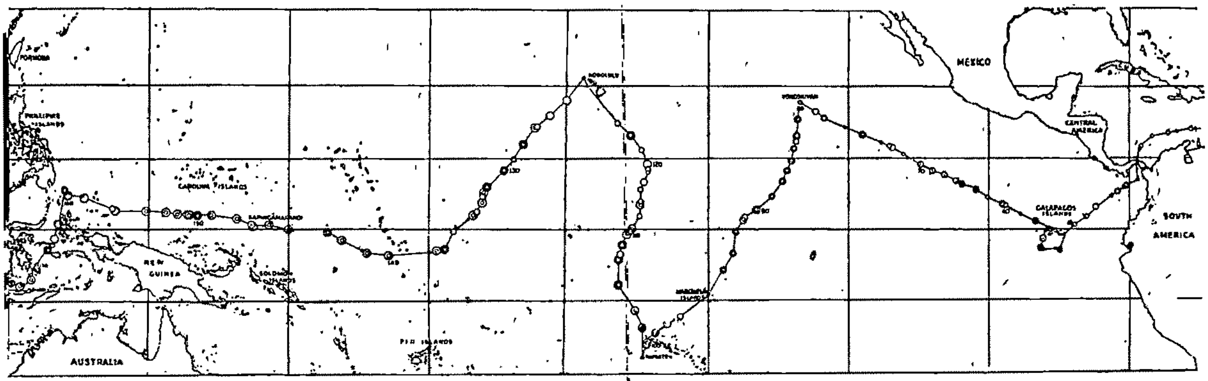
Landings made at different ocean islands afforded opportunities for making botanical collections and photographic studies of animals and plants.

Measurements of the thickness of sediment by means of recording echoes from exploding depth charges were made frequently along our course. Except near Panama, where higher values were found, no reflecting layers could be discovered below the 1,000-ft. level, in striking contrast with the much deeper echoes found in the Mediterranean and in the open Atlantic Ocean.

After proceeding through the Sunda Archipelago to Soerabaya, raising sediment cores displaying volcanic ash layers and taking hydrographic soundings under way, the expedition started on its cruise into the Indian Ocean on February 18, 1948, from Bali. Strong winds, approaching hurricane force in the squalls, made work impossible during the first week; but afterwards weather conditions were ideal. Such was not the case, however, with the state of the sea bottom, the ruggedness of which made both core sampling and measurements of sediment thickness precarious. The number of cores raised from the eastern Indian Ocean was therefore unexpectedly small—a total length of only 60 metres—and the loss of instruments was relatively heavy.

An interesting feature on our echograms was a perfectly flat bottom at a depth of about 4,300 metres, which extended for several hundred nautical miles from near the equator towards the coast of Ceylon, where the depth over long stretches did not vary by more than a few fathoms. Here the core sampler was broken in two, proving that the bottom was hard, with very thin cover of sediment (an extensive lava bed ?).

Following from Colombo a course towards the south-south-east, we again passed over the southern hemisphere, afterwards setting course for the Seychelles. The cores raised from the western Indian



Track of the *Albatross* across the Pacific. The circles indicate the stations occupied

Ocean were more numerous than in its eastern parts; and especially after leaving the Seychelles on a northerly course over the Somali Deep they displayed very pronounced stratification. In the Gulf of Aden as well as in the southern part of the Red Sea in its northern part, the rocky nature of the bottom made core-sampling precarious—the lowest parts of the cores frequently gave off a smell of sulphureted hydrogen, indicating a deficient oxygenization of the bottom waters.

As earlier in the Pacific, our numerous soundings of the thickness of sediment made in the Indian Ocean gave very moderate depths for the reflecting layer, rarely exceeding 200 metres and frequently less than 100 metres.

The hydrographic soundings included two sections across the equatorial current system, where again indications of fish-shoals (or other densely packed pelagic organisms) were found on the echograms. The *Albatross* was considerably delayed coming up the Red Sea by a strong northwester, and arrived at Suez on May 8, having thus devoted two and a half months to the Indian Ocean and to the Red Sea.

OBITUARIES

Sir Clifford Paterson, O.B.E., F.R.S.

SIR CLIFFORD COPLAND PATERSON, director of the Research Laboratories of the General Electric Co., Ltd., Wembley, died at the Watford Peace Memorial Hospital on July 26, shortly after returning from Australia, where he had been acting as contact between British and Australian scientific bodies.

Born on October 17, 1879, Paterson was educated at Mill Hill School and Finsbury Technical College under Silvanus Thompson. After serving a four-year apprenticeship in an engineering works in London he obtained further practical experience in Glasgow and at the Oerlikon Works in Switzerland, going afterwards to Faraday House under Dr. Alexander Russell. From 1903 until 1919 he was principal assistant to Sir Richard Glazebrook at the National Physical Laboratory, and was responsible for the electro-technical and photometric departments. Under his guidance these departments made outstanding contributions in precision methods of measuring electrical power and the establishment of the international standard of light. The Paterson–Walsh electric height finder for indicating automatically the heights of aircraft was developed during the First World War.

Paterson joined the General Electric Co., Ltd., in 1919 to establish the research laboratories of that Company, of which he was made a director in 1941. The progress of so highly technical an industry as electrical engineering depends essentially on scientific research, and the research laboratories which grew up around the achievements and personality of Paterson are representative of the finest of their kind. Starting with a staff of twenty-nine, the General Electric Research Laboratories now employ 1,750 people. Working under the inspiration and guidance of Paterson a distinguished team have made valuable contributions to developments ranging from heavy engineering to electronics. In lighting and vision, fields in which Paterson's greatest personal contributions to science were made, they have been outstanding, as well as in many other branches of applied physics.

The successful prosecution of the War demanded the speedy solution of new problems requiring the application of scientific principles. Radar was a notable example—employed first for the detection of enemy aircraft, then for naval purposes for detection and intricate gun ranging. In this and in many other directions, the facilities and the personnel of the General Electric research organisation under Paterson's direction were a great national asset.

Paterson was a man of great personal charm. His high principles and great integrity in his business, professional and personal relations were so well recognized by all with whom he came into contact that there is no need to stress them. His wide interests and the confidence imposed in him and the esteem with which he was regarded are reflected in the numerous high offices which he held in his profession, and the honours and awards conferred upon him. He was a past president of the Institution of Electrical Engineers, the Institute of Physics, the Electrical Research Association, the Illuminating Engineering Society, the International Commission on Illumination, the Institution of Illumination Engineers in Charge, and the Junior Institution of Engineers. He had been vice-president of the Royal Institution and chairman of council of the British Standards Institution. He was on the Advisory Council of the Department of Scientific and Industrial Research and a member of the Executive Committee of the National Physical Laboratory. He received the degree of D.Sc. (*honoris causa*) of the University of Birmingham in 1937, he was elected to the fellowship of the Royal Society in 1942, awarded the Faraday Medal of the Institution of Electrical Engineers in 1945, and the Ewing Medal by the

Council of the Institution of Civil Engineers in 1947. He was knighted in 1946. The last of his many honours, the Gold Medal of the Illuminating Engineering Society of America, was presented shortly before his death.

He was immensely proud of the City of London's tribute to him when during the last two years of the War he was Master of the Worshipful Company of Tallow Chandlers.

Paterson was a notable and delightful lecturer, and was at his best when his subject lent itself to experiment and demonstration. Among his outstanding lectures and papers may be mentioned the Faraday Lecture of the Institution of Electrical Engineers, "The Free Electron"; the Guthrie Lecture, "The Appraisement of Lighting"; the J. J. Thomson Jubilee Lecture, "The Electron Liberated"; and the British Association York Meeting, "The Use of Photocells".

Opportunities for relaxation and recreation to a man of Paterson's capacity for devotion to the service of his Company and the profession of which he was so distinguished a member were few; but his hobbies of gardening and yachting were a never-failing source of interest and delight to him. His garden, which Lady Paterson and he planned themselves, and the original formation of which was largely the result of their own labours, was much admired by all who were privileged to see it. The majority of his holidays were spent in his yacht on the River Deben at Waldringfield.

By Paterson's death the engineering profession suffers an inestimable loss. The records of his work remain, and are available. Through the great organisation which he built up his influence will be perpetuated; but we shall miss his sound and mature counsel, which grew out of his accumulated experiences and widespread contacts and activities.

Lady Paterson, two sons and a daughter survive him.

A. P. M. FLEMING

Mr. J. R. Cowie

On August 5, Mr. John R. Cowie died aged sixty-six leaving a widow, two sons and one daughter. Chairman of the Council of the Electrical Research Association since the spring of this year, he had been a member of the Council since 1924. This long association with industrial research was particularly concerned with circuit-breaking phenomena and switchgear, which was the first and remains the largest item of research and development in the Association's programme.

Mr. Cowie was especially qualified for leadership both by experience and character. A native of Scotland, he was educated in Edinburgh (Watson's and the Heriot-Watt College) and Glasgow. Apprenticed to William Thomson and Co., he also worked with the British Electric Plant Co., and William Beardmore and Co., before joining the Glasgow Corporation, where he was associated with the late Mr. Lackie and Sir Archibald Page and concerned, *inter alia*, with the Dalmarnock power station and the raising of steam pressures. He joined A. Reyrolle and Co. twenty-seven years ago and was southern area manager at the time of his death. During this period he was associated with most of the great electrical developments in London and in the South and West of England and Wales. He served on the Council of the Institution of Electrical Engineers during 1919–22, and in 1937 was president of the Association of Mining, Electrical and Mechanical Engineers. His influence in the electrical industry was great. Few leading engineers had the same depth of experience and association with great and new projects both on the supply and the manufacturing sides. No one was more trusted, or, indeed, more trustworthy. In negotiation and in matters of discretion his wise counsel and his strong principles were ever in request. His clearness of thought, sincerity and frankness of expression were nevertheless allied to great kindliness. He was a loyal friend and his help was freely given to those who approached him. His subordinates thought as highly of him as his colleagues. He was esteemed not only by engineers but also by those he met in his many sports and hobbies—rugby, hockey, golf, fishing, horticulture and dog-breeding. His convictions inspired respect and his character affection.

S. WHITEHEAD

We regret to announce the following deaths:

Dr. P. R. Lowe, O.B.E., formerly keeper in charge of ornithology, British Museum (Natural History), on August 18, aged seventy-eight.

Prof. A. F. C. Pollard, emeritus professor of physics in the Imperial College of Science and Technology, University of London, on August 15, aged seventy.

Prof. S. W. J. Smith, F.R.S., emeritus professor of physics in the University of Birmingham, on August 20, aged seventy-seven years.

NEWS and VIEWS

Sociology in the London School of Economics: Prof. D. V. Glass

The University of London has just established a new chair of sociology, tenable at the London School of Economics, and has elected Dr. D. V. Glass as the first occupant. This, the third chair in sociology in the School, is designed to promote teaching and research in the sociology of contemporary society and in current methods of collecting and analysing data obtainable by field studies and social surveys. It is therefore a post which offers great opportunities, and Dr. Glass' experience is particularly relevant. He is well known as a demographer of international repute, his most substantial work in this field being "Population Policies and Movements in Europe". He has for many years been research secretary of the Population Investigation Committee and was put in charge of the Family Census by the Royal Commission on Population. His interests have always been more in the social aspects of population than in pure statistical demography. He served his apprenticeship in social research under Prof. Lancelot Hogben, undertaking studies of educational opportunity in Great Britain, and he also published a little book on "The Town" in 1935. All this suggests that he is likely to turn his attention to such questions as family and household structure, local and occupational groups, and social mobility and stratification. These are all eminently subjects for the study of which the chair has been instituted.

The British Institute of Archæology, Ankara: Mr. Seton Lloyd

Mr. Seton Lloyd, who (as announced in *Nature* of August 14, p. 250) has been elected to the directorship of the recently founded British Institute of Archæology in Ankara, started his career as architectural assistant to Sir Edwin Lutyens, and gained his early archæological experience in Egypt during the late 'twenties. During 1930–37 he worked under Dr. Henri Frankfort, as field supervisor to the Iraq Expedition of the Chicago Oriental Institute, and there gained an exceptionally detailed knowledge of mound-excavation on a wide variety of Mesopotamian sites. During this period he had the satisfaction of recovering many now famous art treasures from the rich Sumerian temples of Tell Asmar and Tell Ajrab. Next came two seasons with the Neilson Expedition under Prof. J. Garstang at Mersin in Turkey, where a stratified excavation of extreme complexity gave full scope to his particular talent. Since 1939, as technical adviser to the Directorate of Antiquities in the Government of Iraq, he has been indirectly responsible for a succession of astonishingly successful excavations, which have not only preserved the continuity of archæological discovery, but also raised his Department from a mere administrative service to a unique position as a research institution. Indeed, it would be difficult to over-estimate the debt which Mesopotamian archæology already owes to Mr. Lloyd's technique and the new generation of Iraqi excavators to his guidance. His name is now coupled with those of Mallowan and Woolley as one of the most gifted and successful excavators of our age. On him devolves the task of training those of the coming generation, and it could not be in better hands. His publications show him to be a good all-round archæologist and good artist, with a scholarly as well as a scientific outlook. The new Institute thus makes an auspicious start.

Botany in Nigeria: Prof. F. W. Sansome

The new University College in Nigeria is fortunate to have secured Dr. F. W. Sansome as its first professor of botany. Dr. Sansome received his undergraduate training in Edinburgh as an agriculturist. Upon this foundation he added, at first in Glasgow and later at the John Innes Horticultural Institution, a thorough training in botany and genetics. At this time Dr. Sansome carried out important work on tetraploidy in tomatoes, and published (with Dr. Philp) "Recent Advances in Plant Genetics", which rapidly ran through two editions. He then became senior lecturer in the Botany Department in the University of Manchester, and assistant director of the Experimental Grounds, with responsibilities in horticultural botany and genetics. He devoted his energy, with great success, to the building up of facilities for horticultural research, and the Jodrell Bank Station owes its efficiency to Dr. Sansome's work. Dr. Sansome's infectious enthusiasm has endeared him to horticulturists and students in the north of England, and his wisdom and wit and generosity are greatly appreciated by his colleagues. The good wishes of professional botanists and a large general public will accompany him on his new venture. It is a pleasure to know that his wife, who is distinguished for her research on cytology, is to be a research fellow in Ibadan, and will continue her work there.

Veterinary Science in Bristol: Prof. F. Blakemore

In 1943 the Committee on Veterinary Education, of which Dr. T. Loveday was chairman, recommended that a new school of veterinary science should be established in the University of Bristol. With the concurrence of the Ministry of Agriculture and Fisheries and of the University Grants Committee, the University has undertaken to carry out this recommendation. Plans are far advanced for the additional buildings required, and the small estate of Langford is available as a field station. It is proposed to admit students to the first year of study in the autumn of 1949. The University has recently appointed, as its first professor of veterinary medicine, Mr. F. Blakemore, who is at present superintending veterinary investigation officer for England and Wales. Mr. Blakemore received his veterinary education at the Universities of Liverpool and Manchester. After some experience in practice he served as veterinary officer for the county of Glamorgan, and as veterinary investigation officer for the Eastern Provinces. In 1946 he was appointed to the post he now relinquishes. He has been responsible for the teaching of general hygiene in the University of Cambridge. Mr. Blakemore has carried out extensive work on fowl paralysis and on various diseases of lambs, calves and pigs. He was the first to identify fluorine poisoning of stock in Great Britain and has traced its relation to industry. Recently he has been engaged in the study of mineral deficiency diseases in cattle.

Marin Mersenne (1588–1648)

On September 1 occurs the tercentenary of the death of the French ecclesiast, mathematician and philosopher, Marin Mersenne, whose correspondence with his contemporaries, published in 1933–37, sheds much light on the history of physical science. Born on September 8, 1588, at La Souitiède, Sarthe, he was educated at the Jesuit College at La Flèche, where for a short time he had Descartes—eight years his junior—as a school-fellow. From La Flèche, Mersenne went to Paris to study at the Sorbonne, and about 1616 entered the religious order of Minim Friars, an offshoot of the Franciscans. From 1616 until 1619 he was professor at the College of Nevers and thence onwards was superior of the Convent of his Order in Paris. He travelled into Germany, Holland and Italy, translated Galileo's "Mechanics", and held small gatherings of mathematicians and the like in his room in the Convent, thus anticipating the inauguration of the Royal Academy of Sciences.

Auguste Henri Forel

Neurologist, psychiatrist, entomologist, eugenist, temperance and penal reform advocate, Auguste Henri Forel was born a century ago, on September 1, 1848, at Morges, Canton Vaud, in Switzerland. His childhood studies of ants culminated in the publication, at the age of twenty-six, of "Les Fourmis de la Suisse", of which Darwin confessed that seldom in his life had he been more interested by any book. Studying medicine at Zurich, Forel specialized in psychiatry and was appointed professor of psychiatry in the University and director of the Insane Hospital. The more important works of this indefatigable and versatile man include "Der Hypnotismus und die Suggestive Psychotherapie" (1889), "Hygiene der Nerven und des Geistes" (1903) and "Die Sexuelle

Frage" (1905). The last was translated into sixteen languages, and the year of his death witnessed the publication of a sixteenth edition. It was described by Havelock Ellis as "without doubt the most comprehensive, and taking into account its many-sidedness, perhaps the ablest work which has yet appeared on the sex question". When he was fifty, Forel gave up teaching and devoted himself to the pursuit of his bewildering variety of interests. In 1912 he had a stroke, which resulted in permanent paralysis of his right hand. To the literature of auto-pathography he contributed an interesting account of his dysphasia in the *Journal für Psychologie und Neurologie*, of which he was founder and editor. His autobiography "Out of My Life and Work" (English translation, 1937) is a frank and fascinating self-portrait of one of the most picturesque scientific figures of modern times. He died in 1931.

The *Philosophical Magazine*: 150th Anniversary

THE *Philosophical Magazine* was first published in 1798, and the board of directors and the editorial board have every reason to be proud of the journal's record during its long life of a hundred and fifty years. The title-page to the first volume indicates a breadth of interest "comprehending the various branches of science, the liberal and fine arts, agriculture, manufactures and commerce". Succeeding volumes of the *Magazine* have achieved for it an international reputation as a scientific journal in the realm of physical and mathematical science. David Brewster, John Tyndall, William Thomson, Oliver Lodge, J. J. Thomson are names to be found in the list of editors who succeeded Alexander Tilloch and Richard Taylor, and it is not surprising that such men of science have been responsible for the publication of important papers by research workers in various fields, including those of relativity and atomic physics. The traditionally high standard of the *Philosophical Magazine* has been well maintained, and we wish the periodical every success on the journey towards the two hundredth anniversary of its foundation.

To mark the hundred and fiftieth anniversary of the founding of the *Philosophical Magazine*, a special commemoration number has been edited by Dr. Alan Ferguson under the general title "Natural Philosophy through the Eighteenth Century and Allied Topics" (Pp. viii+164. London: Taylor and Francis. 15*s*.). This is a most useful survey, and includes articles on astronomy through the eighteenth century by Sir H. Spencer Jones, physics by Prof. Herbert Dingle, chemistry by Prof. J. R. Partington, and mathematics by Dr. J. F. Scott. An appropriate review by Engineer-Captain Edgar C. Smith provides interesting material on the achievements of civil engineering. Among the allied topics dealt with are: scientific instruments by Mr. Robert S. Whipple, the scientific periodical from 1665 to 1798 by Dr. Douglas McKie, and the teaching of the physical sciences at the end of the eighteenth century by Dr. F. Sherwood Taylor. The whole volume is both interesting and instructive, containing a wealth of information which enhances its value as a book of reference.

The Night Sky in September

NEW moon occurs on Sept. 3d. 11h. 21m. U.T., and full moon on Sept. 18d. 09h. 43m. The following conjunctions with the moon take place: Sept. 4d. 18h., Mercury 3° S.; Sept. 6d. 22h., Mars 0·7° S.; Sept. 10d. 13h., Jupiter 4° N.; Sept. 29d. 13h., Venus 6° S.; Sept. 30d. 05h., Saturn 4° S. In addition to these conjunctions with the moon, the following conjunctions take place: Sept. 9d. 10h., Saturn in conjunction with Regulus, Saturn 0·8° N.; Sept. 20d. 16h., Mercury in conjunction with Spica, Mercury 0·2° S. Mercury sets at 19h. 15m., 18h. 45m. and 17h. 52m. at the beginning, middle and end of the month, respectively, and is too close to the sun for favourable observation. The planet reaches its greatest eastern elongation on Sept. 25. Venus is a morning star, rising at 1h. 15m., 1h. 30m. and 1h. 55m. at the beginning, middle and end of the month, respectively; it has a stellar magnitude of approximately − 3·8 throughout most of September, and can be observed with phase a little more than half moon most of the time. The planet attains its greatest western elongation on Sept. 3. Mars sets at 20h. 10m. and 18h. 50m. at the beginning and end of the month, respectively, and is too close to the sun for favourable observation. Jupiter can be seen for some time after sunset, the times of setting being 22h. 25m. and 20h. 40m. on Sept. 1 and 30, respectively, but the planet lies rather low for good observation in northern latitudes. Saturn rises at 4h. 10m. and 2h. 35m. at the beginning and end of the month, respectively, and can be seen as a morning star, stellar magnitude 0·9. One occultation of stars brighter than magnitude 6 occurs as follows: Sept. 27d. 01h. 43·5m., 47 Gemi. (*R*), where *R* refers to reappearance; the latitude of Greenwich is assumed. Autumnal equinox commences on Sept. 23d. 03h.

Announcements

DR. G. H. S. BUSHNELL has been appointed curator of the Museum of Archæology and Ethnology in the University of Cambridge.

Mr. B. C. Clayton and Mr. V. D. O. Smyth have recently been appointed advisory officers at the Research Station of the Board of Greenkeeping Research, St. Ives Research Station, Bingley, Yorkshire.

UNDER the auspices of the Society of Chemical Industry, a conference on "Dust in Industry" will be held at the University of Leeds during September 28–30. Further information can be obtained from the General Secretary, Society of Chemical Industry, 56 Victoria Street, London, S.W.1.

A CONFERENCE on "Modern Applications of Liquid Fuels" will be held at the University of Birmingham during September 21–23, under the joint auspices of the Institute of Petroleum and the Institute of Fuel. The president will be Mr. J. A. Oriel. Further information can be obtained from Mr. R. W. Reynolds-Davies, General Secretary, 18 Devonshire Street, London, W.1.

A CONVENTION on "High Vacua" will be held at Gleneagles, Perthshire, during October 12–13, under the presidency of Sir Charles Darwin. Further information can be obtained from Mr. L. L. Maitland, British-American Research, Block E.2, Hillingdon North, Glasgow, S.W.

A DISCUSSION on "Meteors" will be held in the Physical Laboratories of the University of Manchester on September 9. It will be opened by Dr. F. L. Whipple of Harvard University; other speakers will include Mr. J. P. M. Prentice, Dr. J. G. Porter, Mr. N. Herlofson and Dr. A. C. B. Lovell. Further information can be obtained from Dr. Lovell at the above Laboratories.

Behaviour of a Particle of Very Small Mass in a Magnetic Field

It would seem at first sight that a particle of very small mass, such as accompanies β-disintegration or electron-capture, and significant magnetic moment μ, would be very difficult to observe. According to Bethe[1], it should have a fairly high ionizing power and a correspondingly small penetration into matter. Moreover, if it already possesses a charge *e*, the uncertainty principle should play a part in all cases where experimental evidence on μ would be sought[2]. However, for an ultra-relativistic particle (that is, a particle with a high ratio of kinetic mass to rest mass) special considerations come into play which may modify the generally accepted conclusions.

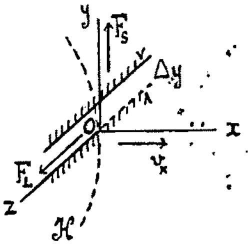
A Dirac particle can be considered as a spherule which is both magnetized and carries an electric charge. As Frenkel[3] has pointed out, if the particle has a magnetic moment $\vec{\mu}$, an electric moment $\vec{\pi}$, of the same order of absolute value, must necessarily appear. Moreover, when the speed approaches *c*, the three vectors $\vec{\mu}$, $\vec{\pi}$ and $\vec{c}$ tend to become orthogonal[4]. The magnitude of the moment $\vec{\mu}$ should vary with the speed if it could have any direction whatever. However, in the case where the moment $\vec{\mu}$ is orthogonal to the direction of the displacement, the former has the properties of invariance, as described by Louis de Broglie[5], who pointed out that the densities of moments $\vec{\mu}$ and $\vec{\pi}$ form the six components of an antisymmetrical tensor of the second order: the main moments that are obtained by integration from these densities have invariant values. Thus, in the relativistic case, moment $\vec{\mu}$ would always tend to follow the orthogonal direction and to be invariant in this.

Let us write the uncertainty relation in a new form that is better adapted to high speeds:

$$\Delta x \,.\, \Delta\eta \geqslant \frac{h}{m_0 c}, \text{ where } \Delta x \,.\, \Delta v \geqslant \frac{h}{m_0 \eta^3} \qquad (1)$$

$$(\text{for } \Delta p = m_0 c \,.\, \Delta\eta = m_0 \eta^3 \, \Delta v).$$

In the diagram, particles (e,μ), with a speed v_x in the direction Ox, cross a long slit in the Z direction which has the width Δy.



The Lorentz force at the origin O is $F_L = ev_x\, H(O)$. The width Δy of the slit introduces in this force an uncertainty

$$\Delta F_L = e\left[v_x\left(\frac{\partial H}{\partial y}\right)\Delta y + H(O)\Delta v_x\right],$$

which we must compare to the force F_S due to spin. The ratio of these forces, with $\mu = eh/4\pi m_0$, will be

$$\frac{\Delta F_L}{F_S} = \frac{4\pi m_0}{h}\left[v_x \Delta y + \frac{H}{\partial H/\partial y}\,\Delta v_x\right], \qquad (2)$$

putting, from (1),

$$\Delta y \geqslant \frac{h}{m_0 \eta^3 \Delta v_y} \text{ and } \Delta v_x \geqslant \frac{h}{m_0 \eta^3 \Delta x}. \qquad (3)$$

(2) then becomes

$$\frac{\Delta F_L}{F_S} \geqslant \frac{4\pi m_0}{h}\left[\frac{h}{m_0\eta^3}\cdot\frac{v_x}{\Delta v_y} + \frac{h}{m_0\eta^3}\,\frac{H}{\partial H/\partial y}\,\frac{1}{\Delta x}\right], \text{ or}$$

$$\frac{\Delta F_L}{F_S} \geqslant \frac{4\pi}{\eta^3}\left[\frac{v_x}{\Delta v_y} + \frac{H}{\partial H/\partial y}\,\frac{1}{\Delta x}\right].$$

The term in brackets being obviously greater than 1, we finally get

$$\Delta F_L/F_S \geqslant 4\pi/\eta^3, \qquad (4)$$

and the magnetic moment μ will be observable if

$$\eta^3 \geqslant 4\pi, \qquad (5)$$

a condition that is obviously fulfilled for every relativistic particle.

The magnetic moment of a charged light particle might thus be found.

Even if we deny invariance to the magnetic moment and allow that its absolute value might decrease as the kinetic mass of the particle increases, the various expressions which have been given[6] for the conditions of observability remain, with a power of η diminished by one unit, and the conclusions are unchanged.

The foregoing considerations are of a very general character. The question will be examined afresh with the Dirac method. On the other hand, I shall shortly show that a relativistic particle may give a weaker ionization when traversing matter than was previously thought. This arises both because of the orthogonal relation of the electric moment $\vec{\pi}$ to $\vec{\mu}$ and $\vec{c}$, and because of the contracting of the magnetic and electric lines of force in a plane normal to the direction of its displacement.

Feret's Statistical Diameter as a Measure of Particle Size

Various measures of the size of irregularly shaped particles as seen in profile under the microscope have been used, chosen according to their theoretical significance or practical ease of measurement. These include, using Heywood's notation[1,2]: (i) the diameter of the circle of equal area, *d*; (ii) the diameter of the circle of equal perimeter, *D*; (iii) the length of line bisecting the profile area (Martin's statistical diameter[3]), *M*; and (iv) the perpendicular distance between parallel tangents touching opposite sides of the profile (Feret's statistical diameter[4]), *F*. *M* and *F* are determined for randomly oriented particles, thus giving an average value over all possible orientations. *d* is usually regarded as the ideal measure of particles seen in profile, but is somewhat difficult to determine experimentally with precision. It is, however, common practice when sizing very small particles to estimate *d* visually by comparing them with standard reference circles on a Patterson and Cawood or similar type of eyepiece graticule[5,6]. *M* and *F* are convenient to measure in practice with aid of an eyepiece scale or filar micrometer, and have been extensively used by various workers. *D*, or rather the ratio *D*/*d*, termed by Heywood[1] the 'contour ratio', and its reciprocal called the 'degree of circularity' by Wadell[7], have been used in discussing the shape and hydrodynamical properties of particles. For these purposes *D* has usually been determined by direct perimeter measurement of the projected images of particles. It does not appear to have been adopted intentionally in any work known to me as a direct single measure of particle size.

In fact, it can be shown that *D* and *F* are equivalent measures provided that the particle profile is non-re-entrant, a condition which is usually satisfied. This simple identity seems to have been overlooked hitherto in particle-size work. Elementary calculation will demonstrate the relationship for simple geometrical outlines, for example, triangle or rectangle, orientated in all possible directions. The proof in the more general case follows readily by considering each element of the perimeter separately. The three-dimensional equivalent of this result is already well known, namely, that the mean projected area of a three-dimensional particle averaged over all orientations is equal to one quarter of the total surface area of the particle, again with the condition of non-re-entrancy. This latter relationship has been much used in the determination of the specific surface of suspended particles by light obscuration methods[8]. Both results follow from two mathematical theorems given by Cauchy in 1841[9]. The second of these theorems is discussed by Vouk[10].

In a recent paper, Heywood[2] has discussed the various methods of measuring microscopical particles. Judging other measures by comparison with the mean projected diameter, *d*, as standard, he concludes: "The Feret definition of statistical diameter is not recommended on account of the large positive error introduced for elongated particles". Interpretation of the Feret diameter as $1/\pi$ of the perimeter shows that no general correspondence with *d* can obtain for particles of differing shape; but it gives this statistical diameter an important new significance, particularly in connexion with the specification of particle shape and correlated properties.

Projected Area of Convex Bodies

In connexion with photometric determination of specific surface of finely divided material, it is essential to know the relation between the projected area of particles, which is actually measured, and the corresponding surface area. The solution of this problem was first given by A. Cauchy in his "Memoire sur la rectification des courbes et la quadrature des surfaces courbes" (Paris, 1832)[1]. A short account of his results in the form of theorems was later published in the *Comptes rendus*[2], but no formal proof was given. It is the latter paper which is usually referred to in connexion with the above problem.

The relevant theorem states that

$$S = 4\overline{A}, \tag{1}$$

where S is the surface area and $\overline{A}$ the average projected area of the convex body. The average is taken over all possible orientations in space. Although this result has been much used and discussed by many experimental and theoretical workers[3], there still seems to be much confusion and uncertainty as to its general validity. Thus in *Nature* recently[4], Dr. B. A. Scott says that it can be shown that the ratio of surface to projected area for a rectangular parallelepiped in random motion is $18\pi/(8+\pi)$ independent of the relative lengths of the axes. Dr. Scott uses this result to compute the surface area of calcined and hydrated alumina, and obtains a very good agreement between the estimates of the surface area obtained from optical measurement and other methods. Since similar work is going on in our laboratory, Dr. Scott's statement induced us to examine once more the literature on Cauchy's theorem, and we came to the conclusion that an error must have crept into Dr. Scott's calculations.

Since the original Cauchy's papers are not easily accessible and the discussion of the problem presented therein is not always easy to follow, we think it worth while to give a short proof of equation (1) in a slightly different form from that given by Cauchy.

Consider a convex body having a surface area S. Suppose there are no re-entrant surfaces, that is, the surface S cannot be pierced by a straight line on more than two points. We divide S into a large number of infinitesimal surface elements, which can be represented by a vector $\vec{d\sigma}$ having the direction of the outward normal to the surface element and the magnitude numerically equal to its area. The projection dA of such an element on a fixed plane P specified by its normal $\vec{n}$ is given by the absolute value of the scalar product $|\vec{d\sigma} . \vec{n}|$. For the sake of simplicity, we shall suppose that the plane P is perpendicular to one of the axes (for example, the x-axis) of a rectangular co-ordinate system x,y,z. The components of the vectors $\vec{d\sigma}$ and $\vec{n}$ will then be given by: $\vec{d\sigma} = d\sigma\,(\sin\vartheta\cos\varphi\vec{i} + \sin\vartheta\sin\varphi\vec{j} + \cos\vartheta\vec{k}$, and $\vec{n} = \vec{i}$, where $\vec{i}, \vec{j}, \vec{k}$ are unit vectors in directions of the co-ordinate axes, and ϑ and φ are the angles which the vector $\vec{d\sigma}$ forms with positive z and x axes. Since all orientations of the surface element are equally likely, the average value of the projection of $\vec{d\sigma}$ on the plane P is given by:

$$\overline{dA} = \frac{1}{4\pi}\iint\limits_{\omega} |\,\vec{d\sigma}\cdot\vec{n}\,|\,d\omega, \qquad (2)$$

where $d\omega$ is the element of solid angle ($= \sin\vartheta\, d\vartheta\, d\varphi$) and the integration has to be carried out over the total solid angle 4π. Now in optical problems the surface element will contribute to the projection of the body only if its orientation is such that the angle between $\vec{d\sigma}$ and $\vec{n}$ is less than $\pi/2$. Therefore, the right-hand side of equation (2) should be multiplied by a factor 1/2. Thus we have

$$\overline{dA} = \frac{d\sigma}{2\pi}\int_0^{\pi}\int_0^{\pi/2}\sin^2\vartheta\cos\varphi\, d\vartheta\, d\varphi. \qquad (3)$$

The integration of (3) gives

$$\overline{dA} = 1/4\, d\sigma. \qquad (4)$$

Now if there are no re-entrant surfaces, we can consider the elements of the surface of a convex body as giving equal contributions independent of each other to the total average projected area of the body, and we can write

$$\overline{A} = 1/4\iint\limits_{\sigma} d\sigma, \qquad (5)$$

and the proof of the relation (1) is completed.

In the presence of re-entrant surfaces, equation (5) is not valid, since the contributions from different surface elements cannot be taken as independent. Our assumption that a given surface element contributes to the projected area only if the angle between vectors $\vec{d\sigma}$ and $\vec{n}$ is less than $\pi/2$ is no longer true. There will be some orientations of the body in which some of the surface elements will not make any contribution, although their normals form with the normal of the fixed plane P an angle less than $\pi/2$, because of the obscuration effect. Therefore the ratio of the projected to the surface area for such bodies will always be less than 1/4.

For polyhedra it is not necessary to subdivide the surface in infinitesimal elements $d\sigma$. It suffices to calculate the contribution from each of the n faces separately, and to replace the integral in equation (5) by a summation.

The validity of relation (1) can also be shown by computing the projected area of the body as a whole, and integrating over all possible orientations. This method was used by Cauchy in his original paper (1) in the case of an ellipsoid. The calculation is easy for such simple bodies as the cube, the parallelepiped, the prism or the cylinder, but for more complicated polyhedra it becomes very tedious.

Proton Bombardment of Fluorine

CAPTURE γ-rays have been detected in the proton bombardment of most of the light nuclei from Li^7 to Cl^{37}. The yield from a thick target for a single level in the compound nucleus is proportional to:

$$\Gamma_p\Gamma_\gamma/\Gamma. \qquad (1)$$

The presence of a competing mode of disintegration only reduces this yield as much as it increases the total width Γ. Thus, in the case of F^{19}, the most probable transmutation is the short-range α-emission:

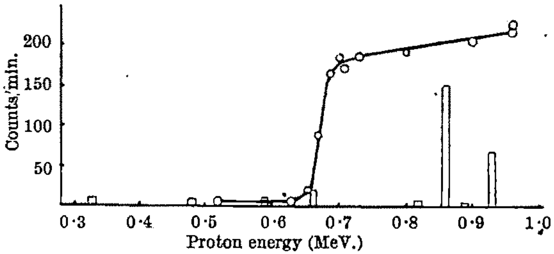
$$F^{19} + H^1 \rightarrow Ne^{20*} \rightarrow O^{16*} + He^4$$
$$O^{16*} \rightarrow O^{16} + h\nu \text{ (6 MeV.)}; \qquad (2)$$

but this should not decrease the probability of γ-emission from the levels of Ne^{20} produced by protons of more than about 600 keV., for in this energy region we expect the proton width Γ_p to exceed the short-range α-particle width Γ_α; and the total width Γ will be determined largely by the former.

The high yield of 6 MeV. γ-rays from (2) does, however, make it difficult to observe the expected capture γ-rays:

$$F^{19} + H^1 \rightarrow Ne^{20*} \rightarrow Ne^{20} + h\nu \qquad (3)$$
$$(Q = 12{\cdot}8 \text{ MeV.}).$$

We used the (γ,n) reaction in Cu^{63} as a threshold (10·9 ± 0·3 MeV.)[1] detector, counting the resulting 10·5-min. activity on thin-wall aluminium β-counters. The accompanying graph gives our results, and also indicates the positions and relative yields of the resonances for process (3)[2]. The shape of the rise between 630 and 700 keV. was compared with the rise in the yield of the 6 MeV. γ-rays, measured simultaneously with a Geiger – Müller γ-counter, and agreement was good. The slow rise between 700 and 960 keV. may be the result of a dirty target, or may indicate the emission of γ-rays from the broad levels[3,4] of Ne^{20}. In either case, it is clear that there is no yield of high-energy γ-rays from the other resonances of reaction (3), comparable with the yield at the 660 keV. resonance.



o, Cu^{62} activity; ⊓, short-range α-particle resonances

The energy available for this transition, 13·4 MeV., does not greatly exceed the threshold of the detector; and Dee, Curran and Strothers[5] found no γ–γ coincidences from fluorine bombarded with protons. It is thus probable that the γ-ray that we detect is the full energy transition to the ground-state.

Having the 590 and 862 keV. resonances available for background runs with the high intensity of 6 MeV. γ-rays alone present, we were able to measure the higher energy γ-rays by the coincidence absorption method, using two Geiger–Müller counters. By this means the angular distribution of the capture γ-ray was found to be isotropic, intensities at 0°, 45° and 90° to the proton beam direction being equal within a probable error of 10 per cent. The yield at the 660 keV. resonance was estimated at 2·2 ± 0·8 per cent of the 6 MeV. γ-rays, giving a radiation width of the order of 2 eV. for this level of Ne^{20}, and less than 0·1 eV. for the others up to 1 MeV. proton energy. This yield is consistent with our measurements with the copper detector if the (γ,n) cross-section of Cu^{63} is about $1 \cdot 5 \times 10^{-27}$ cm.² at this energy[6].

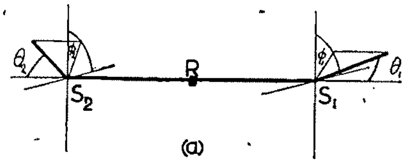
Polarization of Annihilation Radiation

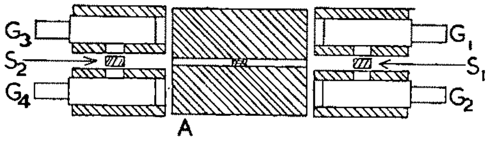
AN attempt has been made to detect the relative polarization of the two photons of energy 0·51 MeV. produced in the annihilation of slow positrons. If pairs of quanta from a source of annihilation radiation at R (Fig. *a*) are scattered at S_1 and S_2, theory[1-3] predicts an angular distribution of quanta after Compton scattering given by the formula

$$N(\theta_1\varphi_1\theta_2\varphi_2)d\Omega_1 d\Omega_2 =$$
$$k\left\{\frac{[(1-\cos\theta_1)^3+2][(1-\cos\theta_2)^3+2]}{[2-\cos\theta_1]^3[2-\cos\theta_2]^3} - \frac{\sin^2\theta_1\sin^2\theta_2\cos 2(\varphi_1-\varphi_2)}{[2-\cos\theta_1]^2[2-\cos\theta_2]^2}\right\}d\Omega_1 d\Omega_2,$$

where θ_1 and θ_2 are the angles through which the quanta are scattered, φ_1 and φ_2 are the azimuthal angles measured in a plane perpendicular to the direction of incidence (S_1RS_2), and $N(\theta_1\varphi_1\theta_2\varphi_2)d\Omega_1 d\Omega_2$ the probability of the two quanta being scattered into elements of solid angle $d\Omega_1$ and $d\Omega_2$ in the directions $(\theta_1\varphi_1)$, $(\theta_2\varphi_2)$.



(a)



(b)

The apparatus for the experimental verification of this formula is sketched in Fig. *b*. Positron-active material, packed into an aluminium tube, is placed at the centre of the lead block A. Oppositely directed quanta pass down the collimating channel to strike the cylindrical scatterers S_1 and S_2. Lead shields define the solid angles into which quanta must be scattered to reach the Geiger counters G_1, G_2, G_3 and G_4. Coincident discharges of either G_1 or G_2 with either G_3 or G_4 are recorded when all four counters lie in the same plane (coplanar position), and when one pair of counters is rotated through 90° about $S_1 S_2$ (perpendicular position), corresponding to mean values of $(\varphi_1-\varphi_2)$ of 0° and 90° respectively. The total numbers of discharges in each pair of counters (of which 70 per cent are due to quanta scattered by S_1 or S_2) are recorded and used to calculate corrections for source decay and chance coincidences.

Sources of Cu^{64} (12·8 hr. half-life) were prepared by deuteron bombardment of copper in the Cambridge cyclotron; each had an initial activity of about 3×10^8 positrons per sec., and gave useful counting rates over a period of 36 hours after irradiation. The results from thirteen such sources are condensed into the accompanying table. The first results were obtained with brass scatterers 1 in. long and 0·6 in. in diameter; later, aluminium scatterers of the same dimensions were used to minimize the effect of double scattering. Two different arrangements of lead shields surrounding the counters were used, the first defining rather larger solid angles for detection of the scattered quanta than the second. Corrections have been made for source decay, chance coincidences, and a background-rate of 3 per hr. due to cosmic rays. The net coincidence-rates at the beginning of each run were of order 0·5 per min. The errors quoted are standard deviations calculated assuming normal statistical fluctuations, and are compatible with the variations in the results from individual sources.

Scatterer material		Brass	Brass	Aluminium
Lead shield arrangement		Wide angle	Narrow angle	Narrow angle
$\frac{\text{Counting-rate (perpendicular pos.)}}{\text{Counting-rate (co-planar pos.)}}$	(theory)	1·55	1·82	1·86
,, ,, ,, ,,	(experimental)	1·39 ± 0·07	1·31 ± 0·17	1·51 ± 0·10

The results establish the existence of a relative polarization. Further experiments are needed, however, to determine whether the discrepancies between theoretical prediction and experimental results are merely instrumental, or due to a breakdown of theory.

The deviations appear too large to be dismissed as due to statistical fluctuations, especially as the independent results using different scatterers are all consistently lower than the theoretical predictions. Any double scattering of quanta within the scatterers would tend to reduce the observed ratio; the increase in the observed ratio with the lower density scatterers may be significant. A rigorous calculation of such an effect is not feasible; rough calculations indicate that it should not be serious. The Geiger counters are being replaced by scintillation counters; an expected twenty-fold increase in detection efficiency will permit the use of smaller scatterers of low-density material, more close defined geometry, and increased counting-rates, and so settle definitely whether or not the theoretical predictions are quantitatively correct.

Note added in proof, August 21. The results of Bleuler and Bradt[4] are noted. Their value for the ratio of perpendicular to coplanar coincidence-rates, while in agreement with theory, has a sufficient margin of error to be compatible with the results quoted here.

Origin of Cosmic Ray Stars

As yet, the absorption of the star-producing radiation has only been measured in air. Nevertheless, the variation of the intensity of single tracks recorded in photographic plates under various lead absorbers has been measured at high altitude and at sea-level[1,2]. The decrease of single tracks with a given lead absorber is found to be much less than the decrease of stars in an equal weight of the atmosphere. Perkins[2] has shown that the number of single tracks is proportional to the number of stars, and therefore it appears established that the range of the star-producing component of cosmic radiation expressed in gm./cm.^{2} is larger by a factor of approximately 3 in lead than it is in air.

This difference in range could be caused possibly by the difference in (*a*) density, or (*b*) atomic weight, A, of the two materials. Perkins has assumed the former and has concluded that the stars are produced by an unstable particle. It seems worth while to explore the latter possibility, as this leads to a dependence of the range of the primaries on A, not very dissimilar from that found experimentally.

Thus, it is well known that the nuclear radius is approximately proportional to $A^{1/3}$:

$$R = r_0 A^{1/3}, \text{ with } r_0 \sim 10^{-13} \text{ cm.} \qquad (1)$$

The cross-section, σ, will be πR^2, and the number of nuclei per gm./cm.^{2}, n, will be N/A, where N is Avogadro's number. Hence the mean free path for a radiation interacting strongly with the nuclei will be given by:

$$l = 1/n\pi R^2 \text{ gm./cm.}^2, \text{ or } l = A^{1/3}/N\pi r_0^2 \text{ gm./cm.}^2. \qquad (2)$$

Substituting numerical values, one obtains:

$$l_{\text{air}} \doteq 130 \text{ gm./cm.}^2, \; l_{\text{lead}} = 311 \text{ gm./cm.}^2,$$
$$l_{\text{lead}}/l_{\text{air}} = 2{\cdot}5,$$

which do not differ greatly from the observed values.

Thus, as an alternative to the assumption of unstable primaries, one may equally well assume the primaries to be stable particles having a cross-section for star production given by the so-called geometric cross-section, and hence a range given by (2).

From the known constitution of the Ilford nuclear emulsion, one obtains for the range of the primaries in the emulsion on this basis:

$$l_E = 200 \text{ gm./cm.}^2 = 50 \text{ cm.}, \qquad (3)$$

since $\rho_E = 4$. Let S be the number of primaries crossing 1 cm.^{2} per day, and I the number of stars formed per c.c. per day. Then approximately:

$$S/l_E = I. \qquad (4)$$

Now, at Jungfraujoch, $I \sim 10$ stars/c.c./day, and hence:

$$S \sim 500/\text{cm.}^2/\text{day}, \qquad (5)$$

or, in other words, about 12 per cent of the total corpuscular radiation at this altitude.

This is in rough agreement with Schopper's estimate[3] of the intensity of fast neutrons, based on measurements of the number of recoil protons recorded in plates covered with paraffin. Thus, the assumption that the majority of cosmic ray stars are caused by fast neutrons is not in violent disagreement with the existing data.

Random Association of Points on a Lattice

A LATTICE is defined to be a rectangular array of points each of which may be any one of k colours. In a previous communication[1], I have given the first and the second moments for the probability distribution of the total number of joins between points of different colours, when the probability that any point is of colour r is $p_r \left(\sum_1^k p_r = 1 \right)$ and is independent of the colour of all the other points. A join was there defined as a line between two adjacent points parallel to the axes of the lattice. The present note gives the first and the second moments for the distribution of (1) the number of joins between points of the same colour, and (2) the total number of joins between points of different colours for two- and three-dimensional lattices when all possible joins between adjacent points are included. The first distribution corresponds to Todd's distribution of 'doublets'[2].

(1) *Joins between points of the same colour, say, rth colour.*

(*a*) Two-dimensional lattice: $m \times n$ points:

$$\begin{aligned} \mu_1' &= (4b - 3a + 2)\, p_r^2, \\ \mu_2 &= (4b - 3a + 2)\, p_r^2 \\ &\quad + 8(7b - 9a + 11)\, p_r^3 \\ &\quad - 15(4b - 5a + 6)\, p_r^4. \end{aligned}$$

(*b*) Three-dimensional lattice: $l \times m \times n$ points:

$$\begin{aligned} \mu_1' &= (13e - 9d + 6c - 4)\, p_r^2, \\ \mu_2 &= (13e - 9d + 6c - 4)\, p_r^2 \\ &\quad + 2(325e - 378d + 432c - 488)\, p_r^3 \\ &\quad - (663e - 765d + 870c - 980)\, p_r^4. \end{aligned}$$

(2) *Total number of joins between points of different colours.*

(*a*) Two-dimensional lattice: $m \times n$ points:

$$\begin{aligned} \mu_1' &= 2(4b - 3a + 2)\, \Sigma p_r p_s, \\ \mu_2 &= 2(32b - 39a + 46)\, \Sigma p_r p_s \\ &\quad - 8(39b - 48a + 57)\, \Sigma p_r p_s p_t \\ &\quad - 60(4b - 5a + 6)\, \Sigma p_r^2 p_s^2 \\ &\quad + 120(4b - 5a + 6)\, \Sigma p_r p_s p_t p_u. \end{aligned}$$

(*b*) Three-dimensional lattice: $l \times m \times n$ points:

$$\begin{aligned} \mu_1' &= 2(13e - 9d + 6c - 4)\, \Sigma p_r p_s, \\ \mu_2 &= 2(338e - 387d + 438c - 492)\, \Sigma p_r p_s \\ &\quad - 2(1677e - 1926d + 2184c - 2456)\, \Sigma p_r p_s p_t \\ &\quad - 4(663e - 765d + 870c - 980)\, \Sigma p_r^2 p_s^2 \\ &\quad + 8(663e - 765d + 870c - 980)\, \Sigma p_r p_s p_t p_u. \end{aligned}$$

In all these expressions, $a = m + n$, $b = mn$, $c = l+m+n$, $d = lm + mn + nl$, and $e = lmn$. The summations are taken for all values of r, s, t and u such that $1 \leqslant r < s < t < u \leqslant k$.

All the distributions tend to the normal form when l, m and n tend to infinity.

The corresponding results when the lattices consist of a fixed number of points of the various colours, say $n_1, n_2, \ldots n_k$, have also been worked out. These results, being long and complicated, will be given in another communication to be published shortly.

Difference – Differential Equations

THE general linear homogeneous difference-differential equation with constant coefficients is

$$\Lambda(y) \equiv \sum_{\mu}\sum_{\nu} a_{\mu\nu} y^{(\nu)}(t + b_\mu) = 0, \qquad (1)$$

where $0 \leqslant \mu \leqslant m$, $0 \leqslant \nu \leqslant n$, $y^{(\nu)}(t)$ is the ν-th derivative of the unknown function $y(t)$ and $0 = b_0 < b_1 < \ldots < b_m$. Particular examples of this equation have appeared in radiology[1,2], economics[3,4] and the theory of control mechanisms[5,6]. The most useful 'boundary conditions' are also the most convenient from the theoretical point of view; we suppose assigned the values of $y(t)$ in an initial interval $0 \leqslant t < b_m$. In terms of these given values, we define a function

$$\varphi(s) = \sum_{\mu}\sum_{\nu} a_{\mu\nu} \exp(b_\mu s) \times$$

$$\left\{ \int_0^{b_\mu} y^{(\nu)}(u) e^{-su} du + \sum_{\lambda=0}^{\nu-1} s^{\nu-1-\lambda} y^{(\lambda)}(0) \right\}.$$

(In particular cases this usually reduces to something fairly simple.) It is obvious that $y = \exp st$ is a solution of (1) for any s satisfying

$$\tau(s) \equiv \sum_{\mu}\sum_{\nu} a_{\mu\nu} s^\nu \exp(b_\mu s) = 0.$$

The zeros of $\tau(s)$ are infinite in number; but their asymptotic behaviour is readily calculable[7]. Under suitable conditions, the solution of (1) is

$$y(t) = \sum_{s} \frac{\varphi(s) \exp st}{\tau^1(s)}, \qquad (2)$$

where s runs through all the zeros of $\tau(s)$. I here assume that $\tau(s)$ has no double zero; if it has, a slight modification must be made in the corresponding term. The series in (2) is convergent and its sum is $y(t)$ (i) for all t, if $a_{mn} \neq 0$ and $a_{0n} \neq 0$, and (ii) for all $t > b_m$, if $a_{mn} \neq 0$. (2) was first given by Hilb[8], but under conditions which would exclude most of the applications. A detailed proof of its validity under the conditions stated will be published shortly[9].

The most interesting question about $y(t)$ is how it behaves when t is large and, in particular, whether $y(t)$ becomes small, periodic or large. This requires a study of the zeros of $\tau(s)$. In any particular case the behaviour of the large zeros can be determined from Langer's theory[7]. If these zeros all have their real parts negative, so that the corresponding terms in $y(t)$ are damped, attention must be directed to a finite number of non-large zeros. This problem for the particular cases in which

$$\tau(s) \equiv s(s + \alpha)e^s + \beta_1 + \beta_2 s + \beta_3 s^2$$

and

$$\tau(s) \equiv s^2 (s + \alpha_1)e^s + (\beta_1 + \beta_2 s)(\alpha_1 + \alpha_2 s)$$

has been discussed by Hartree and others[5,6]. Another special case, into which the equations occurring in radiology[1] and in economics[3,4] may be trivially transformed, is the equation

$$y'(t + 1) + \alpha y(t) = 0 \qquad (\alpha > 0).$$

For this, $\tau(s) \equiv se^s + \alpha$. If $\alpha < \frac{1}{2}\pi$, all zeros of $\tau(s)$ have their real parts negative and $y(t) \to 0$ as $t \to +\infty$, whatever the initial conditions. If $\alpha > \frac{1}{2}\pi$, at least two zeros of $\tau(s)$ have their real parts positive and $y(t)$ oscillates with increasing amplitude as $t \to +\infty$, except under very special initial conditions. For $\alpha = \frac{1}{2}\pi$, there is a periodic solution $y = A \sin(\frac{1}{2}\pi t + B)$ with arbitrary A and B, and the general solution approaches this as t becomes large. There is a periodic solution for $\alpha = 2k\pi + \frac{1}{2}\pi$, where k is any whole number, but the general solution oscillates infinitely unless $k = 0$.

The non-homogeneous equation

$$\Lambda(y) = v(t), \qquad (3$$

where $v(t)$ is a known function, can also be solved for those $v(t)$ which have a readily calculable Laplace transform. Of course, if any particular solution of (3 can be found, the problem of finding the general solution, or the solution satisfying 'boundary conditions' of our type, is reduced to the same problem for (1), just as in the theory of differential equations.

More substantial and more interesting problems are presented by linear difference – differential equations with variable coefficients[10] and by non-linear equations[11]. The only published application of such a non-linear equation known to me occurs in Lord Cherwell's investigations by probability methods into the distribution of prime numbers[12].

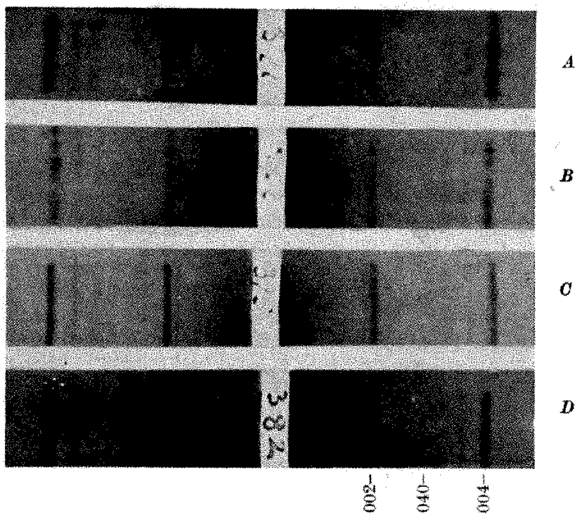
X-Ray Diffraction Effect Shown by some Specimens of Chrysotile

IN a study of the 'tailed' spots occurring on X-ray fibre photographs of chrysotile a camera with a slit approximately 0·7 cm. high was used, so that nearly 1 cm. of the fibre was irradiated. The purpose was to obtain lines instead of spots in the X-ray photograph, and thus facilitate photometry. The lines obtained, however, were beaded, the effect being particularly evident with specimens from Barberton (Figs. *A* and *B*). A specimen from Thetford showed only a slight variation in intensity along the lines (Fig. *C*), and a Russian specimen showed no visible variation. The effect can be imitated to some extent by pinching at regular intervals a specimen not showing it (Fig. *D*).

The beadiness seems to be due to a fairly regular variation of the scattering power along the fibres, possibly due to variation in external conditions during their growth. It is not due to multiple foci in the X-ray tube or irregularities in the slit system, since the beads move up and down with the specimen when its position is changed; they are not shown by all specimens, and are independent of the tube and camera used. It is unlikely that they are caused by non-uniform mechanical deformation of the fibres in detaching them from the lump, since they were shown by a specimen 0·10 cm. × 0·14 cm. in cross-section, which was quite rigid and could not bend to any extent during detachment.



(*A*) Specimen of chrysotile from Barberton, South Africa. (*B*) Another specimen from Barberton. (*C*) Specimen from Thetford, Canada. (*D*) Specimen *C*, pinched at intervals

We are grateful to Dr. F. A. Bannister, of the British Museum (Natural History), for verifying the existence of the beadiness with his apparatus, and to Dr. F. J. North, of the National Museum of Wales, for the gift of specimens. Part of the apparatus used was purchased with a grant from the Royal Society

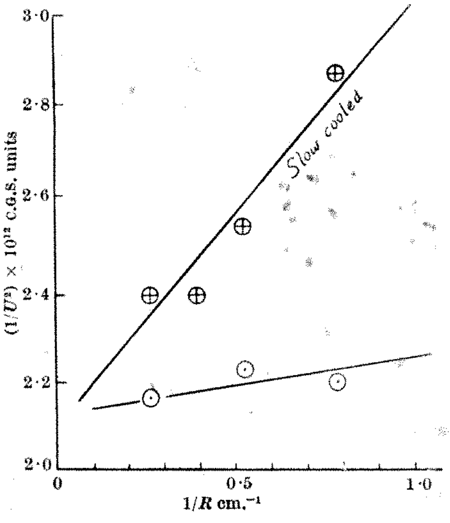
Low-Order Detonation in Solid High Explosives

The recent communication[1] of Jones and Mitchell reporting the existence of a specific stable 'low' velocity of detonation in the case of crystalline or granulated T.N.T. is of considerable interest in that it emphasizes the importance of grain size in low-density unconfined charges. I have obtained similar results in the case of heavily confined cast T.N.T. charges, in which the grain size can be varied over fairly wide limits by variation in casting technique and alteration in the rate of charge cooling.



Velocities of detonation were measured over 30-cm. intervals by the Dautriche method with calibrated I.C.I. Cordtex as the standard detonant. Heavy copper confinement (3·2 gm./sq. cm. of charge surface) was employed, and measurements were made at a number of different charge diameters. The detonation velocities obtained with two widely different rates of charge cooling are summarized in the accompanying graph. It will be seen that plots of $1/U^2$ against $1/R$, where U is the observed velocity of detonation and R the charge radius, are approximately linear in character; but the slope of the line increases markedly with decreased cooling rate. The two experimental lines thus obtained are, of course, only two representatives of an infinite number possible between certain limits. These 'low' detonation velocities obtained by slow cooling were apparently stable in the sense that no change in velocity could be detected over 24 in. of charge length. The reduction in detonation velocity effected by slow cooling was very considerable, amounting to as much as 850 m./sec. at a charge diameter of 1 in., and cannot, therefore, be explained in terms of density changes, since these were very slight even at the slowest cooling rates.

Hydrodynamical calculations of detonation velocity assume that decomposition occurs at constant volume, under which condition it is dependent only on the heat of detonation and the density of the explosive. It has been known for some time, however, that in the case of solid high explosives, the detonation velocity normally decreases with decreasing charge radius. The best explanation of these detonation values lower than the hydrodynamic detonation velocity is on the basis of the lateral energy loss hypothesis of H. Jones[2]. In the case of solid high explosives, decomposition rarely occurs at constant volume since the process of chemical decomposition requires a very small but nevertheless finite time for completion. There is, therefore, behind the detonation front a region of finite length where equilibrium conditions have not yet been established, and which is usually termed the reaction zone. As a result of the very high pressures developed, some lateral expansion of the detonation products may occur in the region of the reaction zone, that is, before decomposition is complete, so that the maximum temperature and pressure are not developed. This will result in an energy decrease at the detonation front, with an attendant diminution in the velocity with which the detonation wave is propagated through the explosive.

The lateral energy losses will be a function of: (1) the charge radius; (2) the degree of confinement; (3) the 'reaction time' of the explosive, or the time required for the primary decomposition process, since this will determine the length of the reaction zone, and hence the time during which 'effective lateral expansion' can occur.

From the present series of experiments, in which considerable velocity changes have been produced at constant charge diameter and confinement by alteration in the rate of charge cooling, it would appear that the 'reaction time' of cast T.N.T. is a function of the rate of charge cooling. Since it is well established that the crystal size is very dependent on the rate of charge cooling, it seems very probable that the 'reaction time' of cast T.N.T. is a function of crystal size, increasing with increasing crystal size. The bearing of this crystal size – reaction time relationship on the mechanism of the detonative decomposition and the physico-chemical processes occurring in the detonation wave will be discussed fully in a paper to be published shortly.

I acknowledge my thanks to the Chief Scientist, Ministry of Supply, for permission to publish this letter.

Anomalous Magneto-Resistance Effects in Bismuth

The change of electrical resistance of bismuth in magnetic fields has been extensively studied, and the investigations of Kapitza[1] and subsequent workers on single crystals have led to the conclusion that the increase in resistance is proportional to the square of the field-strength in weak fields, becoming linear in strong fields. In the course of an investigation into the behaviour of thin fibres of bismuth, we have obtained results which indicate that in certain circumstances the resistance may undergo a small decrease at low field-strengths.

Fibres of bismuth in an envelope of soda glass may be prepared by hot-drawing and a wide variation in diameter is readily obtainable. The range in our experiments was about 5–150 μ. For various orientations of the magnetic field the resistance has been measured as a function of the angular displacement of the specimen. With the axis of rotation parallel to the specimen and perpendicular to the field, the resistance 'cycles' have a periodicity of π. A typical example is shown in Fig. 1.

Comparison of such results with those obtained for single crystals[2] leads to the conclusion that, in general, the fibres are single crystals with the main cleavage plane parallel to the axis.

For a given orientation, the resistance may be plotted against field-strength. In the case of certain fibres the curve so obtained is anomalous in that the change of resistance is negative for a certain range of field strength. The effect is illustrated in Fig. 2, which was obtained with a fibre orientation corresponding to the minimum of Fig. 1.

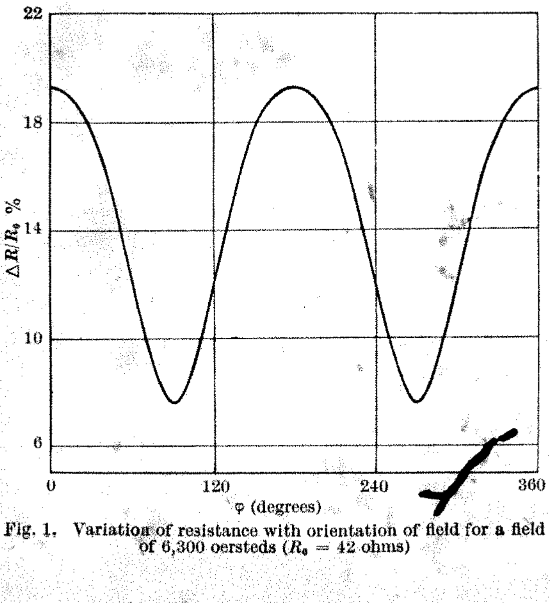

Fig. 1. Variation of resistance with orientation of field for a field of 6,300 oersteds (R_0 = 42 ohms)

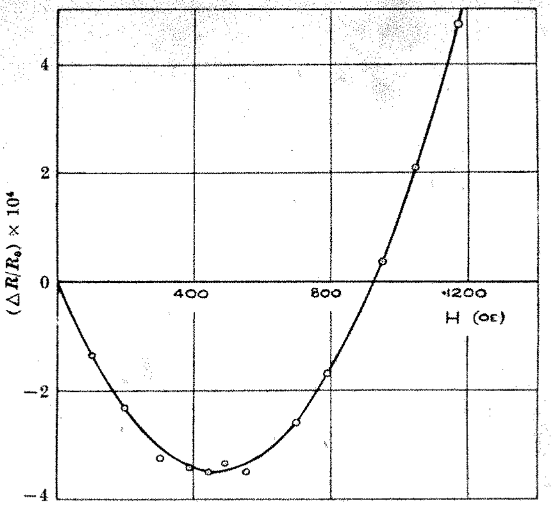

Fig. 2. Dependence of resistance on field-strength, illustrating the negative change

The anomalous change is quite small, and it will be seen that at the minimum of Fig. 2 it is of the order of 4 parts in 10^4. At first sight, a possible interpretation would appear to be in terms of a Hall E.M.F.; but the form of the specimens makes this unlikely and, moreover, the phenomenon does not appear with all fibres.

A negative change in resistance has been predicted on theoretical grounds by Meixner[3] for certain relative orientations of current, field and crystal axis. No previous experimental evidence is known to us, with the possible exception of a paper by Casimir and Gerritsen[4]. The latter, however, attribute their apparent *Umkehreffekt*, obtained with a single crystal, to the presence of a Hall E.M.F. In the case of our specimens, it would seem that while the direction of the current is normally parallel to the main cleavage plane, cases sometimes occur in which this is no longer the case.

A more detailed discussion will be presented elsewhere.

Excited States of Silver Bromide and Iodide

It appears that study of the absorption spectra of the silver halide vapours has, with the exception[1] of silver chloride, hitherto been confined to wavelengths above about 2500 A. We have recently photographed the absorption spectra of silver bromide and iodide in the range 2150–3000 A. with a Hilger medium quartz instrument. Within rather critical pressure limits, red-degraded absorption bands are observed in the region 2150–2475 A. for silver bromide and 2150–2350 A. for silver iodide.

For silver bromide, some forty bands have been assigned to a single system involving a transition between the ground-state[2] and an excited state with constants $\nu_e = 43{,}537\cdot4$, $\omega_e = 205\cdot0$, $x_e\omega_e = 0\cdot74$ cm.$^{-1}$. The vibrational constants refer to ^{109}Ag^{81}Br.

In the spectrum of silver iodide in this region, there appear to be two partly overlapping systems, resulting from transitions from the ground-state to two excited states :

C. $\nu_e = 44{,}717\cdot7$, $\omega_e = 158\cdot1$, $x_e\omega_e = 2\cdot3$ (for ^{107}AgI),
D. $\nu_e \sim 46{,}000$, $\omega_e \sim 165$ cm.$^{-1}$.

Thirty bands have been assigned to system $C \leftarrow N$, 17 to $D \leftarrow N$.

The products of dissociation cannot be determined unambiguously; but the most likely products are Ag(^2P) plus halogen (^2P) for all three excited levels.

The relations between the states of the silver halides are summarized below, where k_e is the force-constant in dyne/cm. × 10^{-5}, and ν_e is the system-origin in electron-volts. There seems to be little doubt that the new levels are analogous to the levels C and D of silver chloride.

State		AgCl	AgBr	AgI
D	ν_e	6·05	—	5·7
	k_e	$1\cdot3_2$	—	$0\cdot9_3$
C	ν_e	5·40	5·40	5·54
	k_e	1·318	1·149	0·85
B	ν_e	3·92	3·88	3·87
	k_e	1·226	0·894	0·521[3]
N	ν_e	0	0	0
	k_e	1·832	1·678	1·453

The 'Renal Threshold'

According to the definition of Barclay *et al.*[1], the 'renal threshold' can be expressed as a rate of tubular reabsorption per 100 c.c. glomerular filtrate. Thus

$$T = 100\,\frac{Rx}{C}, \qquad (1)$$

where T is 'threshold', Rx is the amount of the 'threshold substance' reabsorbed by the tubules (mgm./min.), and C is clearance of inulin, or mannitol. The same conception of the 'threshold' is also used by Harrison *et al.*[2].

In 1945 I published with Szenes[3] a paper entitled "Aglucosuric Blood Sugar Concentration"[3,4]; this is a calculated blood sugar concentration, above which filtered glucose is not reabsorbed, but passes into the urine. This concentration is thus a dynamic 'threshold'; and the formula can, of course, be used not only in the case of glucose, but also in the case of any other 'threshold substance'.

We deduced the formula of such a threshold substance concentration as follows :

$$Ex = Fx - Rx, \qquad (2)$$

where Ex is excreted substance (mgm./min.), Fx is filtered substance (mgm./min.).

$$\text{But } Ex = \frac{V.Ux}{100};\ Fx = \frac{C.Px}{100};\ Rx = \frac{C.Ax}{100};$$

where V is urine (c.c./min.), Ux is concentration of substance in urine (mgm. per cent), C is clearance of inulin, Px is concentration of substance in blood (mgm. per cent), and Ax is threshold (Szenes and Földi's formula).

$$\text{So } V.Ux = C.Px - C.Ax;\ Ax = Px - \frac{V.Ux}{C};$$

$$\text{but } C = \frac{U.V}{P},$$

where U and P are urinary and plasma inulin concentration (mgm. per cent) respectively.

$$\text{Hence } Ax = Px - \frac{P}{U}\,Ux. \qquad (3)$$

The purpose of the present note is to determine the relation of our formula to Barclay's 'threshold'.

As I have pointed out above, Barclay's formula is :

$$T = 100\,\frac{Rx}{C}.$$

From equation (2) :

$$Rx = Fx - Ex.$$

$$\text{Hence } T = \frac{Fx - Ex}{C}\,.\,100 = \frac{C.Px - V.Ux}{C} = Px - \frac{V.Ux}{C} = Px - \frac{P}{U}\,.\,Ux.$$

Thus Barclay's 'threshold' and our formula are identical. This is noteworthy because we have deduced our formula by means of mathematical considerations, while Barclay chose his definition of the threshold because "plasma values are usually expressed to 100 c.c. and . . . 100 c.c. would appear to be fairly close to the more recent determination of the average rate of filtration in man".

From the equations

$$Rx = \frac{C.Ax}{100} \text{ and } Fx = \frac{C.Px}{100},$$

we have

$$\frac{Rx}{Fx} = \frac{Ax}{Px},$$

whence

$$Ax = Px\,.\,\frac{Rx}{Fx}. \qquad (4)$$

This equation shows that the calculated concentration of the threshold substance in the blood is a function of the actual concentration, the rate of tubular reabsorption and glomerular filtration.

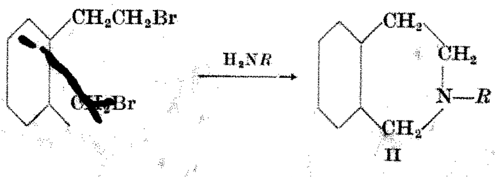
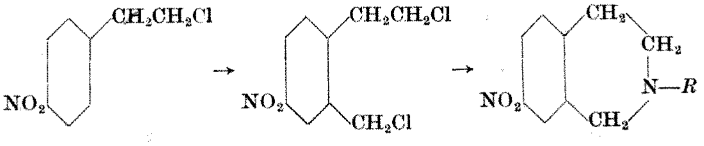
A New Synthesis of 2 : 7-Disubstituted-1 : 2 : 3 : 4-tetrahydro-*iso*-quinolines

It has been shown by Holliman and Mann[1] that *o*-2-bromoethyl-benzyl bromide (I) condenses readily with primary amines to give 2-substituted-1 : 2 : 3 : 4-tetrahydro-*iso*-quinolines (II). Although hitherto



this has apparently been the only known method for the synthesis of 2-aryl-*iso*-quinolines of type (II), it has one serious disadvantage, namely, that for various reasons it does not lend itself to the preparation of *iso*-quinolines of this type having substituent groups in the benzene ring. The presence of such groups may be essential if the tetrahydro-*iso*-quinoline is to possess marked physiological action. To overcome this difficulty we have developed the following synthesis.



III IV V

2-Phenyl-ethyl chloride on nitration affords *p*-nitrophenyl-ethyl chloride[2] (III), which we find undergoes ready chloromethylation to the crystalline 5-nitro-2(2-chloroethyl)-benzyl chloride (IV). We have condensed this compound with several primary amines to obtain in each case the corresponding 7-nitro-2-aryl-1 : 2 : 3 : 4-tetrahydro-*iso*-quinoline (V). These *iso*-quinolines have in turn been converted to their 7-amino, 7-acetamido and other derivatives. The preparation of the dichloride (IV) is much simpler than that of the dibromide (I), and thus affords a ready route to these 7-substituted-*iso*-quinoline derivatives.

2-Phenyl-ethyl bromide can be similarly nitrated and then bromomethylated to form 5-nitro-2(2-bromoethyl)-benzyl bromide, which also readily gives the above cyclization with primary amines.

We are now investigating the synthesis of the phosphorus and arsenic analogues of compounds of type (V).

Tryptochrome : a Pigment Derived from Tryptophan

When 5 ml. of a very dilute (*c.* 0·05 per cent) solution of tryptophan in 60–80 per cent acetic acid is treated with a drop of 1 per cent aqueous potassium iodate, and warmed to boiling, a violet-pink colour develops, and an intense greenish-orange fluorescence. On dilution with two volumes of water, the pigment gradually separates, and can be extracted with *iso*butyl alcohol or with chloroform, in which solvent it shows a strong absorption band at λ 565–555 mμ, and a weak band at λ 520–515 mμ. Pigment formation requires a large excess of acetic acid, otherwise the mixture turns brown, and an iodotryptophan is precipitated, from which the pigment cannot be generated. The pigment is stable in acid solution, and both tint and fluorescence survive exposure to air and light for months.

The iodate can be replaced by hypochlorite bromate, or free bromine; but the pigment is less pure, and is very easily destroyed by a slight excess of the reagent. Chlorate, peroxide, persulphate, perborate, manganese dioxide, ferricyanide and ferric iron are ineffective for colour production.

The name 'tryptochrome' is suggested for the pigment, since it closely resembles, and may be identical with, the pigment formed in the well-known protein-ochrome reaction, obtained when tryptophan or a trypsin digest of protein is treated with bromine water, and extracted with amyl alcohol. The tryptochrome test will show free tryptophan in dilutions down to about 1 in 100,000. None of the other common amino-acids gives the reaction. On prolonged boiling with sufficient iodate, indole forms a mixture of pigments, including what appear to be indirubin and isatin ; but the conditions are much more drastic than those required for tryptochrome, and persulphate is more effective than iodate. Addition of iodate to a faintly acid solution of adrenaline leads to formation at room temperature of an iodoadrenochrome[1]. Under such conditions, tryptophan gives no colour. Adrenochrome closely resembles tryptochrome in tint, but neither it nor indirubin shows the orange fluorescence characteristic of tryptochrome.

Structure of tryptochrome. (1) Analysis of the product crystallized from a mixture of chloroform and light petroleum gives the percentage composition : C, 69·9 ; H, 4·6 ; N, 13·9, corresponding to the formula $C_{17}H_{14}O_2N_3$. (2) The reaction requires the free α-amino-group of the tryptophan. It is not given by unhydrolysed proteins, or by β-indolepropionic acid, or by tryptophan after treatment with nitrous acid or formaldehyde. (3) The reaction requires an unsubstituted α-carbon in the pyrrole ring. (4) Reduction in acetic acid by magnesium or zinc yields a leuco-product that gives no catechol reaction with molybdate or phenolic reaction with iron. The leuco-product slowly reoxidizes to tryptochrome on aeration. Hence it is concluded that tryptochrome, unlike adrenochrome, is not a quinone.

The evidence now obtained suggests that tryptochrome is an indirubinoid derivative.

The preparation and properties of tryptochrome are being investigated in the Chemical Department of this University by Mr. W. A. Boggust, aided by a grant from the Medical Research Council of Ireland. I am very grateful to Prof. Wesley Cocker for these facilities and for the interest he has taken in the work.

Alkaline Phosphatase and Tumour Inhibition

In the course of bioassays of extracts of normal male urine[1,2] for tumour-inhibiting properties, we have investigated their effect on alkaline phosphatase present in certain tumours by Gomori's histological technique. Similar examinations were carried out using other tumour-inhibitory substances, namely, stilbœstrol[3] and colchicine[4,5].

For the purpose of denoting the quantity of alkaline phosphatase in the tissues under investigation, we have used mouse kidney tissue as a comparative standard. All tissues, treated and untreated tumours and kidney, were incubated in the same jar and their further treatment carried out under identical condions. Inbred albino mice were used as experimental nimals.

(1) *Tumours investigated.* Transplants of Twort-ammary carcinoma, sarcoma and carcinoma induced y subcutaneous inoculation of crystallized methyl-holanthrene, a transplant from the induced car-inoma, spontaneous mammary carcinoma in mice nd their transplant. The Twort-mammary car-inoma shows a high concentration of alkaline phos-hatase, so also do the transplants of the spontaneous ammary carcinoma in the first generation, but a lesser degree. The other tumours referred to bove contained little or no demonstrable alkaline hosphatase.

For the purpose of continuing our investigation wort-mammary carcinoma were used.

(2) *Tumour-inhibiting substances.* (*a*) Toluene tract of urine and certain fractions thereof (pos-bly related to *H* 11), single dose 0·8 or 1·6 mgm.) Stilbœstrol, single dose 0·25 mgm. (*a*) and (*b*) ere dissolved in 0·05 ml. of arachis oil and injected traperitoneally twice a day on seven consecutive ays. (*c*) Colchicine, 0·02 mgm. in 0·2 ml. of water, e mitoses arresting dose[5], given subcutaneously vice a day on three or five consecutive days. Mice ere dissected when their body temperature dropped 32·8° C. or less.

Untreated tumour-bearers or mice treated with achis oil were used as controls.

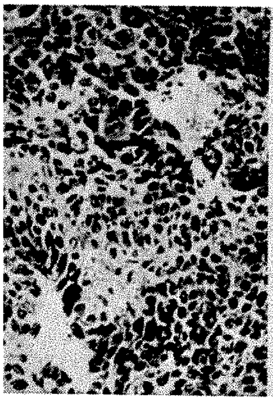

Fig. 1. × 200

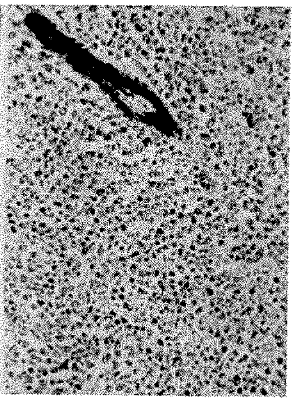

Fig. 2. × 200

Results. (*a*) Urinary extracts : a marked diminution d, in some cases, almost a complete absence of aline phosphatase even in highly cellular portions the tumours. The accompanying photomicrographs control and treated tumours of approximately e same growth-rate and cellularity show these fferences (Fig. 1, injected with arachis oil, 63 sq. m.; Fig. 2, treated with extract, 60 sq. mm. rface area). It was our experience, however, that e amount of alkaline phosphatase demonstrable s approximately inversely proportional to the gree of inhibition of growth.

(*b*) Stilbœstrol : no diminution, but perhaps an rease in alkaline phosphatase. The adrenals of e treated mice, when compared to the controls, ow a marked deposit of alkaline phosphatase in the bcapsular layers of the zona glomerulosa. This pearance may be of interest as it is claimed that generation of the adrenocortical cells commences in is area.

(*c*) Colchicine : alkaline phosphatase diminution e to cellular degeneration of tumours.

The cellular or other structure of each tumour was checked by hæmatoxylin-eosin staining of alternate sections.

It would appear that growth inhibitors present in normal male urine directly or indirectly reduce the alkaline phosphatase content of certain tumour cells.

Effect of Sputum on Streptomycin

In a small series of seventeen cases of whooping cough treated with streptomycin, no beneficial effects were noted. The children receiving parenteral therapy, five hours after injection, had blood-levels of 2–12 units per ml. It was not possible to detect streptomycin in the blood of thirteen patients receiving aerosal therapy after 15, 30, 60 min. or 3 hr. The urine of these patients at no time during 24 hr. showed the presence of streptomycin.

Because of the inability to recover streptomycin after inhalation, *in vitro* tests were devised to observe the behaviour of streptomycin in the presence of lung extract, lung tissue, mucin and gastric juice; the sources of these substances were sputum, 6 gm. of guinea pig lung ground in 10 c.c. nutrient broth, 10 per cent potassium hyaluronate and human resting-gastric juice, respectively.

Using the streptomycin assay technique devised by Mitchison, clear-cut results were obtained. The 10-mm. column of assay agar containing *Staph. mayo* was layered with the test material and the zone of growth inhibition of staphylococci was measured.

The mucin of the gastric juice, in contrast to the lung extract, potassium hyaluronate and sputum, allowed full activity of the streptomycin. Sputum was either shaken with streptomycin in a bottle containing glass beads before it was layered on a column of assay agar, or the sputum was layered on the medium and the streptomycin inoculated on top of the sputum. The potassium hyaluronate was shaken with streptomycin before being transferred into the assay tube.

By plotting the zone of growth inhibition in mm. against the logarithm of a known concentration of 2, 3, 4, 5, 10, 50 units streptomycin per ml., a graph was obtained from which the streptomycin content of inoculated material could be read. When layered on to the agar, before incubation, all mixtures were known to have a final concentration of 5 units streptomycin per ml. After 18-hr. incubation these mixtures were shown to contain less than one unit per ml.

Table 1 represents two experiments. The mean in mm. of inhibition and standard deviation of ten tubes for each group is recorded. Table 2 represents the mean and standard deviation of six tubes which were layered with sputum collected from a patient at 0, 3, 6, 9 hr. after having received an intramuscular injection of 1 gm. streptomycin. (Patient's blood

Table 1. Mean and standard deviation of zone of inhibition produced by:

	Sputum shaken with streptomycin	Sputum layered on agar, streptomycin superimposed	Potassium hyaluronate shaken with streptomycin	Streptomycin (10 units/ml.)	Streptomycin (5 units/ml.)
Exp. 1	2·1±0·21	0·5±0·71	2·38±0·37	6·0±0·16	4·7±0·27
Exp. 2	2·9±0·48	0·1±0·32			4·9±0·05

Table 2. Mean and standard deviation of zone of inhibition induced by sputum, before and after parenteral streptomycin

Hours	0	3	6	9	Control, streptomycin 5 units/ml.
	0·5±0·71	0·4±0·44	0·6±0·52	0·6±0·52	4·9±0·05

5 hr. after receiving the streptomycin contained 7 units per ml.)

The differences between the three left-hand groups of Table 1 and either of the two right-hand groups, and the difference between the experimental groups and the control in Table 2 would have happened by chance much less than once in a thousand trials. This means that the difference between the means is highly significant.

The sputum, which was found to be alkaline, prevented the action of streptomycin either by a mechanical inhibitory action, or by a chemical inactivation, but not as a result of an acid reaction.

This observation helps to explain why organisms normally sensitive to streptomycin fail to be affected when embedded in sputum. The unsuccessful streptomycin trial in whooping cough may possibly be explained in this way. The disappointing results in the treatment of pulmonary tuberculosis can be understood, for on this basis tubercle bacilli, lying in sputum which has rendered the antibiotic sublethal, multiply and become resistant. The tubercle bacilli free in the spinal cord are destroyed, whereas those embedded in exudate at the base of the brain survive. When the tubercle bacilli lie on surface lesions such as ulcers of the larynx or vocal cords, the response to treatment is dramatic; but open phthisis is proving resistant to treatment.

Thanks are due to the Non-tuberculosis Streptomycin Trials Committee for the streptomycin and to Dr. B. Woolf and Miss E. Duncan for the statistical assay.

Reconstruction of Laccase from its Protein and Copper

THE conception that oxidases are metallo-protein compounds in which the metal plays an essential part in the catalytic activity of the enzyme was introduced by Gabriel Bertrand[1] in the course of his studies on laccase, the oxidizing enzyme present in the latex of the Indo-Chinese lacquer tree. As crude preparations of laccase contained an appreciable amount of manganese, Bertrand assumed that this metal forms the active part of the oxidase. A more recent study of this problem by Keilin and Mann[2], based upon highly purified enzyme prepared on a large scale from the latex of different lacquer trees, produced evidence that the active metal is not manganese but copper. This view, however, was challenged by Didier Bertrand[3], who claimed to have isolated an enzyme of higher activity which contained 0·15 per cent manganese and only 0·014 per cent copper.

While studying the properties of laccase, an attempt was made to split the enzyme into its two constituent parts and to reconstruct it from its protein and a metal. The method used was that devised by Kubowitz[4] in the course of his study on the polyphenol oxidase of potato. The experiments were carried out as follows:

(1) The activity of the enzyme was tested in the Barcroft manometers. The following system was used: 10 mgm. pyrocatechol or hydroquinone, a suitable amount of laccase preparation, 0·1 *M* phosphate buffer *p*H 6·7 to a final volume of 3·3 ml. The manometer was shaken at about 160 cycles per min. and readings were made for the first six minutes.

(2) Enzyme preparations of activity (Q_{O_2}) varying from 3,000 to 18,000 in presence of pyrocatechol were obtained from the latex of the Indo-Chinese lacquer tree (*Rhus succedanea*) by fractional precipitations with alcohol and ammonium sulphate and by further purification with tricalcium phosphate gel.

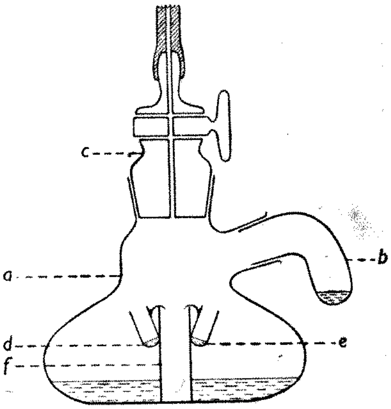

Fig. 1

(3) The splitting of the enzyme was performed in a modified flask of the Barcroft differential manometer (see Fig. 1). The flask (*a*) of about 30 ml. capacity has a side bulb (*b*) with a ground joint so that the contents of the bulb can easily be run into the flask by giving it a half-turn. The flask is provided with a stopper and tap (*c*) which can be connected with a vacuum pump and to a source of pure nitrogen. Two small dangling tubes (*d* and *e*) are suspended by means of platinum hooks from the lip of the centra tube (*f*) fused to the bottom of the flask.

4 ml. of either crude or purified concentrated enzyme preparation and 1 ml. 0·5 *M* phosphate buffer *p*H 7·0 are placed in the flask *a*. The dangling tubes *d* and *e* receive 2 mgm. catechol and 3·2 mgm. ascorbic acid respectively and the side bulb *b* receives 0·03–0·05 ml. 2 *M* potassium cyanide in 0·05 *M* potassium hydroxide. After evacuating the flask and filling it with pure nitrogen, catechol and ascorbic acid are added to the enzyme by dislodging the dangling tubes, and then cyanide is added from the side bulb

The mixture is left standing for 30 min. at room temperature. The flask is then opened and its contents are cooled to 0° C. and saturated with solid ammonium sulphate. The precipitated enzyme is centrifuged off and washed with 50 ml. of saturated ammonium sulphate containing 0·02 *M* potassium cyanide. The precipitate is dissolved in the minimum amount of water and dialysed for 12 hr. at 0° C. against 3 l. of 0·01 *M* phosphate buffer pH 7 and for a further 36 hours against 3 l. 0·005 *M* phosphate, which is changed three times.

The enzyme preparation thus obtained has almost completely lost its catalytic activity in the oxidation of catechol or hydroquinone.

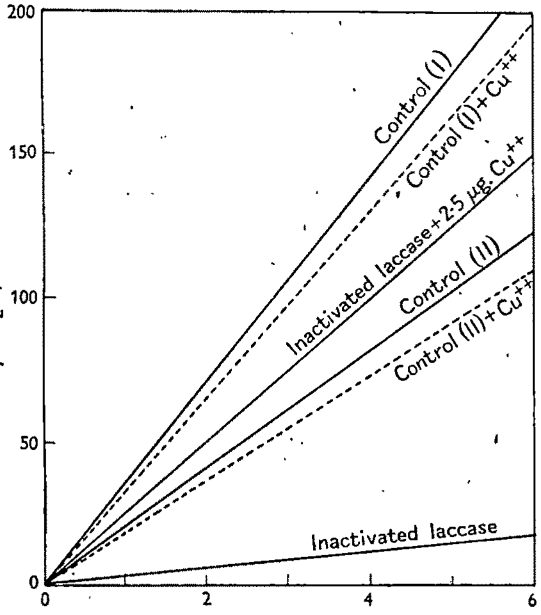

Fig. 2

(4) For the reactivation of this enzyme preparation, 2·5–12 μgm. of cupric, ferric or manganese ions are added (as cupric and ferric sulphates or manganese chloride) to 2 ml. samples of the inactivated enzyme preparation and left standing at room temperature for periods varying from 30 min. to 3 hr. The catalytic activities of these samples were then tested and compared with those of the untreated control samples (I) estimated at the beginning of the experiments, the control samples (II) treated only with ammonium sulphate and dialysed, and the samples inactivated by cyanide treatment. These experiments show that the activity of the cyanide-treated samples of laccase was not affected by the addition of either ferric or manganese ions, but was markedly increased by the addition of very small quantities of cupric ions. Fig. 2, which summarizes the results of the experiments with cupric ions, shows that the addition of 2·5 μgm. of this metal to the inactivated enzyme raised its activity to a level occupying an intermediate position between the controls I and II. That the activity of this reconstructed enzyme is somewhat higher than that of the control II is probably due to the fact that cyanide protected the protein of the inactivated enzyme from slow but irreversible changes which were proceeding in the control preparation II when it was submitted to precipitation and dialysis. It is important to note that the small concentration of cupric ions which strongly activated the cyanide-treated enzyme had no catalytic effect on the oxidation of either catechol or hydroquinone, and when added to the control enzyme preparations slightly inhibited their activities (Fig. 2).

These experiments clearly demonstrate that laccase is a copper-protein enzyme.

My thanks are due to Prof. D. Keilin, for his help and advice.

Localization of Polyphenoloxidase in the Chloroplasts of *Beta vulgaris*

The chloroplast as the seat of chlorophyll pigments in plants occupies a unique position in the economy of the green cell. In recent years there has been a renewed interest in the reactions and properties of chloroplasts as a result of the work of Hill[1,2] and Hill and Scarisbrick[3,4], who demonstrated that the reaction characteristic of photosynthesis in green plants, the evolution of oxygen, occurs in appreciable quantities in isolated chloroplasts under the influence of light and in the presence of suitable oxidants.

In the course of an investigation of oxygen evolution by isolated chloroplasts, it was deemed important to explore their enzymatic composition. Of special interest were considered enzymes capable of participating in oxidation-reduction reactions and, more particularly, those localized principally, if not entirely, in the chloroplasts. This communication presents evidence that a copper enzyme, polyphenoloxidase (otherwise known as tyrosinase or catecholase), is localized in the chloroplasts of spinach beet (chard), *Beta vulgaris*.

In a preliminary experiment, it was found that the addition of catechol to a crude leaf extract of spinach beet leaves was followed by a rapid uptake of oxygen. This suggested the presence of a polyphenoloxidase in the leaves, and it became of interest to determine whether the enzyme is found in the chloroplasts or in the cytoplasmic fluid obtained after the separation of chloroplasts and their fragments.

Leaves of plants grown in sand cultures were mashed in a Waring blender and the green extract fractionated by high-speed centrifugation (approximately 25,000 *g*) into a suspension of chloroplast fragments and a 'cytoplasmic fluid' practically free of chlorophyll.

Polyphenoloxidase activity of the two fractions was tested by using catalytic amounts of catechol with ascorbic acid as a substrate[6]. Consistent with the well-established[6,7] copper-protein nature of polyphenoloxidase, the activity of this enzyme in the chloroplasts was inhibited with cyanide and carbon monoxide. The carbon monoxide inhibition was insensitive to light[6]. The enzyme was also inhibited by more specific copper poisons such as sodium diethyldithiocarbamate[8].

The procedures used for disintegrating leaves were necessarily drastic and resulted in disruption of cytoplasmic bodies, including the chloroplasts. The possibility was therefore considered that the localization of polyphenoloxidase activity in the chloroplasts could be attributed to preparatory technique. On *a priori* grounds this was considered unlikely: the enzyme persisted in the chloroplast fragments and was absent from the cytoplasmic fluid, into which it would be expected to pass in case of disruption of the chloroplasts. Nevertheless, experiments were carried out with the experimental procedures modified in several respects, giving special attention to differences in technique which might have accounted for such divergent reports as were found in the literature.

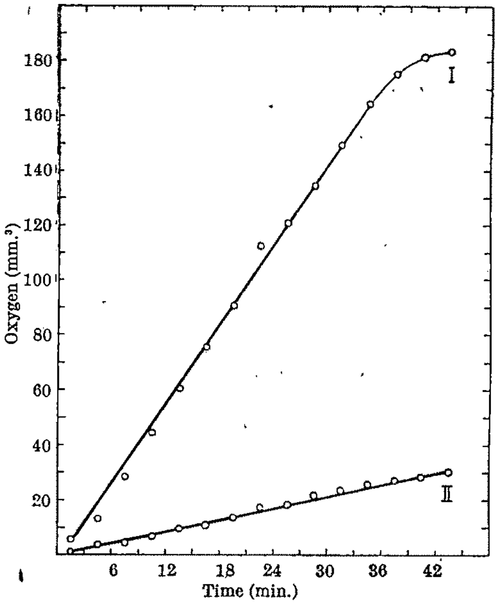
First, the possibility was considered that if the enzyme were originally present in the cytoplasmic fluid, then the high-speed centrifugation used for separating the chloroplast fragments might have sedimented the enzyme as well. This point was tested by adding a crude potato polyphenoloxidase to the leaf mash prior to the high-speed centrifugation. Upon subsequent fractionation of the mash into chloroplast fragments and cytoplasmic fluid, the added potato polyphenoloxidase was recovered in the cytoplasmic fluid. The polyphenoloxidase activity of the chloroplast suspension was not enhanced.

Warburg and Lüttgens[9], working with similar preparations from spinach and sugar beets, attributed about a quarter of the polyphenoloxidase activity of the crude green leaf extract made at *p*H 6·5 to chloroplast suspensions and the remaining three-quarters to the cytoplasmic fluid. These authors considered the *p*H of the extract important. At an acid reaction, at *p*H 5 for example, they found that a major portion of the cytoplasmic polyphenoloxidase was precipitated and in a subsequent centrifugation was recovered with the chloroplast fragments.

Although the preparations used in this investigation were uniformly made at *p*H 6·5, it was undertaken to test the effect of hydrogen ion concentration on the distribution of polyphenoloxidase by extracting the chloroplast suspension at the more alkaline *p*H 7·3. The results indicated that, as with other preparations, the polyphenoloxidase activity of leaf extracts made at *p*H 7·3 was also localized in the chloroplasts.

Bonner and Wildman[10] studied the respiration of spinach leaves and concluded that polyphenoloxidase is their terminal oxidase. Unlike the present findings, however, these authors reported the presence of polyphenoloxidase as confined to the cytoplasm rather than to the chloroplasts. The technique used by Wildman and Bonner[11] involved grinding the chloroplasts in a Charlotte colloid mill, with resultant disintegration of chloroplasts into chlorophyll-containing granules and non-chlorophyllous 'stroma'. These authors[11] are aware that their conclusions as to the distribution of enzymes between chloroplasts and cytoplasm can be properly interpreted only with reference to their own manipulative technique. It was already noted that in the same plant, spinach, Warburg and Lüttgens[9] found polyphenoloxidase both in chloroplast fragments and in cytoplasm. The spinach-beet used in the present investigation is a chenopodiaceous plant related to sugar beet and spinach.

It seemed desirable, in view of the results of Bonner and Wildman[10], to subject the already disrupted chloroplasts comprising the chloroplast suspensions used in this investigation to further disintegration. This was done by grinding the green leaf extracts with glass beads for 10 min. in a Mickle tissue-disintegrating machine, prior to the high-speed centrifugation. A microscopic examination of the ground chloroplast suspension disclosed uniform round particles more than 1 millimicron in diameter. This further subdivision of the chloroplast fragments failed to dislodge the polyphenoloxidase. As before, the enzyme was found in the chloroplast suspension rather than in the cytoplasmic fluid. The results are presented in the accompanying graph.



Polyphenoloxidase activity of chloroplast fragments and cytoplasmic fluid of spinach beet. Curve I: disintegrated chloroplast suspension containing 0·8 mgm. of chlorophyll. Curve II: cytoplasmic fluid containing 0·02 mgm. chlorophyll, after removal of disintegrated chloroplasts. Reaction mixture contained 2·4 mgm. ascorbic acid and 0·02 mgm. catechol in $M/15$ potassium phosphate buffer (*p*H 6·5). Temperature of bath, 20° C.

The localization of a copper-protein oxidase in cellular bodies so intimately identified with the process of photosynthesis raises at once the question of the possible participation of this enzyme, directly or indirectly, with one or more of the biochemical reactions which are linked with the process of photosynthesis in those green plants which contain polyphenoloxidase[12]. The answer to this question must await further experimentation.

A full account of these experiments will be published elsewhere.

DEFINITIONS OF BOND-ENERGY IN PHYSICAL CHEMISTRY

THE expression 'bond-energy' continues to be used in at least two senses: (*a*) for the *mean* contribution from each bond of a given type to the total heat, $-\Delta H$, of formation of the molecule from its constituent atoms; (*b*) for the energy, ΔH, required to disrupt the molecule at a particular bond into two fragments.

As was first pointed out by Fajans[1], and later developed by Sidgwick and Pauling, the 'bond-energy', usage (*a*), of a given bond X—Y, shows a remarkable degree of constancy over a wide range of compounds, provided that the valency of neither X nor Y alters. But the 'bond-energy', usage (*b*), may vary markedly with the molecular environment of the bond. Despite frequent warnings[2], confusion between these two interpretations of 'bond-energy' still exists, and it seems to us desirable that the simple but ambiguous expression 'bond-energy' should be abandoned in favour of two separate expressions specific for the usages (*a*) and (*b*).

For usage (*a*), the expression 'mean bond-energy term' has already been proposed[3]. We would further suggest the use of the symbol $E(X\text{—}Y)$ to denote this quantity. The relation between $E(X\text{—}Y)$ and the thermochemical data for a molecule XY_n is given by

$$n\,E(X\text{—}Y) = -\Delta H_{298}$$

for the reaction

$$X_{(g)} + nY_{(g)} \rightarrow XY_{n(g)},$$

that is, the heat of formation of the gaseous compound from the free atoms of its constituent elements, the 'atomic heat of formation'. We suggest the use of a superscript a in discussing enthalpy terms for reactions in which the initial state of the system is that of free atoms, and we follow Bichowsky and Rossini[4] in using Q for $(-\Delta H_{298})$. The particular $-\Delta H_{298}$ term in question, above, has then the symbol $Qf^{a}{}_{(g)}$, which, if considered too cumbersome, might be modified to Q_a. For the heat of formation of the gaseous compound from its elements *in their standard states*, we suggest the symbol $Qf^{s}{}_{(g)}$, while for the $-\Delta H_{298}$ for the formation reaction in which both the set of initial elements and the final compound are all in their standard states, the symbol Qf^0 follows from the universally accepted convention of Lewis and Randall[5].

For the usage (*b*), we would suggest the expression 'bond dissociation energy' and the symbol D together with a specification of the particular bond; for example, $D(XY_{n-1}\text{—}Y)$. In the case of polyatomic molecules there is not necessarily an identity between the quantities $E(X\text{—}Y)$ and the individual $D(X\text{—}Y)$ values, the only connexion being that, for a given molecule, the sum of all the E terms shall equal the sum of the D values for each stage in the stepwise dissociation of the molecule into free atoms.

In constructing tables of mean bond-energy terms, Sidgwick and Pauling adopted the convention of measuring the atomic heats of formation with respect to ground-state atoms. Recently, Long and Norrish[6] have expressed the view that in dealing with compounds of tetravalent carbon, the E values for carbon bonds should be assessed, not from the $s^2p^2\ {}^3P$ ground-state but from the $sp^3\ {}^5S$ excited state. They urge this on the grounds that molecules such as CH_4 (for example) are built up from the tetravalent ${}^5S$ carbon atom and not from the divalent ${}^3P$ ground-state. This change in the zero from which the total energy content is to be measured should be correspondingly reflected in the symbols used; for example, by using Qf^{a*} in place of Qf^{a}, and E^* in place of E. In this connexion we are unable to agree with the statement of Long and Norrish[6b] that Pauling's table of mean bond-energy terms "contains values deficient in the case of links involving carbon", for Pauling's E values are no less true in respect of his definition of a mean bond-energy term than are the E^* values of Long and Norrish, which are based on a different definition.

If one adopts consistently the point of view that in the specific case of tetravalent carbon compounds E^* terms are preferable to, or more significant than, E terms (because of the building up of such compounds from $C({}^5S)$), one must recognize the necessity of discarding E terms in favour of E^* terms for a large number of bonds other than those involving carbon. An example is provided by the beryllium hydride molecule BeH, which, although dissociating to give a ground-state ${}^1S$ beryllium atom, would be considered as built up from the excited ${}^3P$ state; similarly with the sodium chloride molecule NaCl, since this 'derives' essentially from the ion-pair $Na^+\ Cl^-$, despite its dissociation into ground-state atoms. These two examples are relatively simple ones; in others, for example, hydrogen fluoride, HF, it is rather difficult to identify the atomic species from which the molecule is built up. In general, it seems to us that the Pauling convention leads to mean bond-energy terms in a more simple and less ambiguous manner than would result from a consistent application to all compounds of the convention used by Long and Norrish in respect of carbon compounds.

In connexion with their view that, in tetravalent carbon compounds, E^* values are more significant than E values, Long and Norrish make the specific point that it is reasonable to correlate E^* (C—H) in CH_4 with $D(CH_3\text{—}H)$, whereas a correlation with E (C—H) would be meaningless. They develop from this point an attack on the problem of deciding between the two spectroscopically permissible values for 'L_1', the ΔH_0 for the reaction

$$C_{\text{graphite}} \rightarrow C({}^3P)_{(g)}.$$

Their numerical correlation of E^* (C—H) in CH_4 with $D(CH_3\text{—}H)$ leads them to conclude that $(L_1 + x) \sim 190$ kcal./gm. atom, where x is the excitation energy, ΔH_0, for the atomic transition $C(s^2p^2, {}^3P) \rightarrow C(sp^3\ {}^5S)$. Recently, Shenstone[7], by experimental observation, has given the value of x as 96·4 kcal./gm. atom. This throws some doubt on the assessment of $(L_1 + x) \sim 190$ kcal., since such a value would imply that L_1 is less than 100 kcal. The assessment of $(L_1 + x) \sim 190$ kcal. is based on two assumptions: (i) that the bonds in the $\cdot CH_3$ radical are roughly equivalent in strength to those in CH_4 (that is, the 'energy of reorganisation', of the $\cdot CH_3$ radical is small), and (ii) that the tetracovalent state of the carbon atom in CH_4 is identical with the ${}^5S$ state of the free carbon. But, with regard to (i), since we cannot either describe with certainty the character of the C—H bonds in the $\cdot CH_3$ radical (sp^3 or sp^2 bonding ?), or make due allowance for the interaction between non-bonded hydrogen atoms in $\cdot CH_3$ or CH_4, the reorganisation energy cannot be simply estimated, and might be quite different from the value chosen by Long and Norrish; and in respect of (ii) Van Vleck[8], in a detailed discussion of this specific point in 1934, concluded that the 'valence-state' cannot be identified with any one of the six atomic states of the carbon atom corresponding to the configuration sp^3, but is rather to be considered as a linear combination of all six levels (Van Vleck computed that the 'valence-state' lies *c.* 164 kcal. above the ^3P ground-state). Accordingly, although we recognize the power of the argument of Long and Norrish regarding the assessment of L_1, we are unable to accept it as conclusive, and are generally of the opinion that further direct experimental work, probably on the dissociation of CO or CN or on the later stages of the stepwise dissociation of CH_4, is necessary to settle this important problem.

Note added in proof.—In connexion with the final sentence of our note, we would direct attention to the new direct measurement of L_1 by Brewer, Gilles and Jenkins[9] referred to by Pitzer[10]. They obtain the value 170·39 ± 0·20 kcal. for L_1 at 0° K.

I am very grateful to the courtesy of the authors of the foregoing letter and the Editors of *Nature* for the opportunity of appending a reply to the criticisms involved.

In the previous paper with Prof. Norrish[1], the remark that Pauling's listed values of bond-energies contain values which are deficient for links involving carbon is consistent with the fact that Pauling, in his section on the energies of covalent bonds[2], describes the covalent bond by a wave function in which the coefficients of the various ψ values are such that make the bond-energy a maximum. Having thus introduced the concept of bond-energy, Pauling, in comparing thermochemical bond-energies, naturally makes no attempt to divorce their meaning from the wave-mechanical representation, which, on the contrary, would seem to be required by the above definition of Skinner and Springall in the case of compounds of tetravalent carbon. In this connexion, it has frequently been pointed out[3] that the carbon atoms must have the sp^3 configuration to provide the appropriate wave functions. Accordingly, the low values of the carbon bond-energies calculated thermochemically from the ground s^2p^2 state are 'deficient according to Pauling's *usage*, since they bear to the required values no closer relation than the fivepence change bears to the cost of a sevenpenny article for which a shilling has been paid. The two usages are not, in our opinion, based on different definitions, the example quoted by Pauling by way of definition being identical with our manner of definition.

It is true that the same principle must be applied to a large number of bonds other than those involving carbon. Cases in point are the boron trihalides, which require the unpairing of the s electrons on the boron atom and its promotion to the sp^2 configuration. For co-ordinate links to oxygen, on the other hand, as in the amine oxides and oxyacids of chlorine, for example, the question is one of pairing the two unpaired electrons on the oxygen atom, that is, bringing it from a triplet to a singlet state. None of the examples quoted by Skinner and Springall involving varying degrees of bond polarity create any more difficulty to the one point of view than to the other so far as covalent links are concerned, and it is difficult to see their relevance to the discussion. For heteropolar molecules such as Na^+Cl^-, the bond-energy is not to be confused with the ionic attraction, which is related to the dissociation energy by an algebraic function of the ionization energy of the metal atom and the electron affinity of the non-metal atom. In cases such as the BeH molecule, the relevant atomic states required to give a stable molecular orbital are not normally in doubt, even though the dissociation scheme may involve the avoidance of crossed potential energy curves. It is the contention of this note that an application of the principles of electron-pairing to the selection of atomic terms for the derivation of bond-energies does not in itself lead to ambiguity, and that failure to apply these principles has on occasions led to erroneous conclusions, as pointed out previously[1,4].

It is not a fair statement of the facts to say that we assumed the bonds in CH_3 and CH_4 to be roughly equivalent in strength, since these strengths are interrelated with L_2, for which limits were derived in our paper. It likewise follows from these limits that the reorganisation energy of CH_3 on its formation from CH_4 is small. It may need to be pointed out here that, according to the initial definition we gave[1] for the bond-energy E, the energy of reorganisation calculated from experimental data is a *net* effect which includes the effects due to any possible change in the bonding to sp^2 and repulsion between the hydrogen atoms (as well as all other secondary effects within the molecule such as that due to delocalization of the bonding electrons[3]), so that the remarks of Skinner and Springall concerning these factors are beside the point and do not apply here. The same conclusions also follow from the original definition of energy of reorganisation[5]:

$$\text{energy of linkage} = \text{energy of dissociation} + \text{energy of reorganisation}.$$

It is, of course, possible to define bond-energies in such a way that all these effects are separated out, but we adopted the more usual convention of including them.

The remaining point concerning the 'valence-state' of carbon as calculated by Van Vleck[6] is also one of convention. Adopting Van Vleck's convention, it is necessary for the sake of consistency to calculate bond-energies from the 'valence-states' of all other atoms (which in the case of oxygen and nitrogen, for example, are *not* the ^3P and ^4S states respectively), the energies of some of these states having also been calculated[7]. On this basis, the criticism put forward by Skinner and Springall conflicts with their own definitions laid down at the outset of their communication. Again, we adopted the usual convention of referring bond-energies to atomic states. The identification of the tetravalent state of carbon with the ^5S level seemed at the time, in the absence of a spectroscopic value, to be confirmed by the calcuations of Ufford[8] and experimental data concerning he CN radical[1]. The discrepancy with the recent bservations of Shenstone[9] will be dealt with in a uture communication. It is in no sense responsible or the discrepancy between our conclusions and hose of Springall[10] concerning the heat of atomization of carbon, this being due to entirely different easons which are discussed in a forthcoming paper.

In conclusion, it seems to me that the expression 'mean bond-energy term' is an unfortunate choice. As originally employed for polyatomic molecules by Butler and Polanyi[11], a constancy in energy is ssumed for any one kind of link from molecule to molecule, differences in the dissociation energies being ttributed entirely to resonance energy of the resulting adicals. This point of view ignores changes in the nergy of unruptured links during a dissociation process, whereas the statement that bond-energies ccording to Skinner and Springall's usage (*a*) show "a remarkable degree of constancy" seems difficult o maintain in the face of much experimental evidence. f this were so, then every process of the type

$$CH_4 + CO_2 \rightarrow 2H_2CO,$$

n which the number of each type of bond remains he same, would be thermoneutral, whereas this is far from being the case. The example quoted is ndothermic to the extent of about 60 kcal., which must be attributed to changes in the energies of the C—H or C=O bonds or, more probably, both. The xtent to which the bond-energies (as distinct from he dissociation energies) of C—H, C=O and many ther bonds do, in fact, vary has received frequent onsideration in the literature[12].

GERMAN MOTOR ROADS

BEFORE the War much interest was taken in Great Britain in the German *Autobahnen*. Their design and construction were well described then in both the technical and popular press. The system is the only modern road network planned on a national cale and is worthy of most careful study in order that practice in Britain and elsewhere may profit as much as possible from German experience. The ecent B.I.O.S. Overall Report*, entitled "German Motor Roads, 1946", is therefore particularly valuable in that it gives comprehensive information on the present state of these roads. The report, which contains thirty-nine excellent plates, is clearly and uccinctly-written and can be strongly recommended o the general reader.

The roads have been laid out on new ground, independently of existing roads, so as to link the main cities and industrial areas. The great extent of the system is emphasized by the fact that although a length of some 2,380 miles of dual-carriageway road is already in service, only about one half of the length originally planned has been completed. One of the chief impressions gained by the observers was of the high quality maintained throughout rather than of any exceptional excellence in particular sections, which were nowhere better than has been achieved elsewhere. This consistency is attributed to the policy of working to a single standard determined centrally, and of employing contractors carefully selected for their ability to undertake work of such a magnitude. The designs of the later roads were modified in the light of the experience gained from those already in service.

An admirable feature is the absence of extensive cracking of the concrete surfaces; this has been achieved by building on a gravel foundation, the material being imported if it was not already available locally. The elaborate plans adopted at crossings and road junctions to avoid the conflict of traffic lanes are well known; when adequately signposted, these are not found to be confusing. Another striking feature is the design of bridges; a great variety of construction has been used to suit local conditions and the workmanship is described as being of outstanding merit. Fifteen photographs in the report give a good idea of the lightness of effect achieved in over-bridges and of the pleasing design of the under-bridges; the latter carry the roads across valleys and are often larger than are met with in common practice owing to the stringent gradient restrictions which were maintained. Care has also been taken to blend the roads into the landscape by careful location, by rounding the slopes of cuttings and embankments, and by the method of planting adopted.

The report finally concludes that "the lay-out and alignment of the German motor roads are of a sufficiently high standard to suggest a degree of safety and sense of security above that obtained on ordinary main roads in Britain". Undoubtedly we can learn much not only from the felicities of this great experiment but also from its defects, a number of which are recorded and illustrated. R. H. MACMILLAN

CONSTITUTION OF THE PLANETS

MORE than thirty pages of the first part for this year of the Monthly Notices of the Royal Astronomical Society are devoted to "Reports on the Progress of Astronomy", under which is included "The Constitution of the Planets", "Solar Activity", "Comets" and "Double Stars". By far the longest of these is the first, and it is possible to glance at only a few of the points dealt with by Rupert Wildt.

Quite recently our view that satellites could not retain atmospheres has been shown to be incorrect, as methane absorption has been discovered in the spectrum of Titan. The atmosphere of Titan, which is stable under present conditions, would have its stability endangered if its temperature were raised by only 100° C. Hence, if the evolution of the satellite passed through a stage of high surface temperature—as is believed to have happened with all the members of the solar system—the atmosphere of Titan must have been formed subsequent to that period. Kuiper believes that the same argument applies, with almost equal force, to Mars and perhaps to Venus and the earth also. He points out that the existence of methane on Titan suggests a genetic relation to its primary or to the other giant planets, and shows that the satellite cannot be the product of capture from an elliptical orbit extending into the interior region of the solar system.

At the end of the review it is pointed out that there are four different groups of phenomena which are worthy of some attention as possible clues to the history of the solar system. These are: (1) The correlation between the mass of a planet and the size and composition of its atmosphere-oxides on the terrestrial planets and hydrides on the giant planets. (2) The existence in Saturn's system of two types of satellites with densities greater than that of rock and less than that of water. (3) The nature and origin of the envelopes of low density characteristic of all the giant planets. The theory of Kuhn and Rittmann rules out the possibility of gravitational separation leading to the formation of a heavy core and more especially in the giant planets; and if their view should be accepted, the marked concentration of density towards the centre of the giant planets would favour the accretion theory of planetary formation. (4) The mean chemical composition of the planets in relation to the composition of the sun. As it is possible to explain the scarcity of light elements on the terrestrial planets by dissipation, no further cosmogonic inferences can be made so far as this is concerned. Of course, if the planetary matrix were much richer in lighter elements than the bulk of the sun, some doubts would be thrown on the formation of the planets by sudden ejection from the sun, which would have been accomplished by an unavoidable loss of hydrogen. When more accurate values for the mean composition of the sun and giant planets are available, they may facilitate a choice between the rival theories of the origin of the solar system, through a sudden catastrophe with subsequent rapid condensation, or through gradual accretion.

OSLER AS A SCIENTIST*

By SIR ARTHUR MACNALTY, K.C.B.

SIR WILLIAM OSLER is famous for many things. He was a great physician of two continents, a scholar, a humanist, a teacher and a medical administrator. His work as a scientist has perhaps received less recognition, yet it is revealed on every page of his famous text-book of medicine. As Harvey Cushing wrote[1]: "The volume, indeed, was what might be called a practical pathology in which were given the results of modern investigation, microscopical, bacteriological, and chemical. On this foundation was built up the symptomatology and diagnosis of disease. . . ." His school-master, the Rev. W. A. Johnson, at Weston, near Toronto, introduced him to the study of biology, geology and the use of the microscope. At eighteen years of age, Osler began to tabulate and study his collection of the Diatomaceæ; and his interest in biology was stimulated further, when he entered the Toronto Medical School in 1868, by Dr. James Bovell. "I am at Dr. Bovell's every Saturday and we put up preparations for the microscope," he writes.

His first publication was a short sketch entitle "Christmas and the Microscope" (*Hardwicke's Scienc Gossip*, London, Feb. 1, 1869), in which he describe the diatoms and Infusoria he identified in a bottle c water. In 1870 he presented to the Natural Histor Society of Montreal the results of his studies on th Diatomaceæ of Canada, enumerating 109 specie under twenty-nine genera and describing the structur mode of division and propagation of the diatom[2]. I 1877 he read a paper before this Society on Canadia fresh-water Polyzoa[3] and published a supplementar note on this paper in the *Canadian Naturalist*, 1881 He mentioned a species of *Cristatella* as having bee found in abundance and described a new species c *Pectinatella*.

In 1872–73 Osler had spent fifteen months in th Physiology Laboratory, University College, Londor working at physiology and histology under Pro Burdon-Sanderson. While there he was offered th chair of botany in McGill University; but declined i as insufficiently qualified for the post. At Universit College he began working "On the Action of certai Reagents—Atropia, Physostigma and Curare—on th Colourless Blood-Corpuscles"[5]. The published result were negative. In 1873 he made his most importan contribution to scientific knowledge by investigatin with Edward Schäfer the form and movement of th blood platelets. Though a few previous workers, fo example, Bizzozero and Hayem, had observed thes bodies, "the third element of the blood", it was Osle who saw them first in the circulating blood an carefully described them, and his observations wer presented before the Royal Society by Burdon Sanderson in 1874[6]. Afterwards, he published severa papers and lectures on the blood, including one on th development of blood corpuscles in the bone-marrow All this work established Osler's reputation as a original investigator.

Returning to Montreal in 1874 as lecturer Institutes of Medicine, he studied the 'entozoa', an R. Ramsay Wright, professor of biology at Toront named a trematode worm, which Osler had found the gills of a newt, *Sphryanura Osleri*[8]. Osler, a professor of physiology in the Veterinary Colleg Montreal, and vice-president of the Montreal Vete inary Medical Association, also worked at comparati pathology, being one of the first to realize its impor ance in relation to medicine. He published sever papers on this subject during the next few years. I the first of them, on a form of bronchopneumonia i dogs, he described a previously unknown parasit nematode as the causal agent[9]. This organism w afterwards renamed *Filaria Osleri* by Cobbold i 1879. The most important of the other papers dea with hog cholera[10], echinococcus[11], cestode tube culosis[12] and the parasites in the Montreal po supply[13]. As a by-product of this latter investigatic he took up the subject of trichinosis and echinococc infections in man. He studied the parasites in th blood of the frog, demonstrating and classifying *Ran mugiens*, the *Trypanosoma Sanguinis* (Grubby) an the *Drepanidium ranarum* (Lankester)[14].

Osler confirmed Koch's discovery of the tuberc bacillus as the cause of tuberculosis in 1882; but never became an adept in bacteriological techniqu Harvey Cushing, his biographer, considered that first he inclined towards Bastian's belief in spontaneo generation, and by the time that Pasteur's views ha been accepted, he had abandoned experiment medicine and comparative pathology for the clinic study of disease. The call to Philadelphia to professor of clinical medicine in the University of Pennsylvania in 1884 marks the end of Osler's investigations as a pure scientist in the fields of zoology and physiology. In these fields he had achieved reputation as a trained microscopist and had made important contributions to knowledge. As W. T. Councilman said : "He could easily have become a great scientist, but he chose the path which led to the formation of the great clinician which he became ; a worthy associate of the great men who have made English medicine famous"[15].

---

* A paper read to the Osler Club on July 12.

Already at Montreal Osler had used the microscope in his pathological studies and continued to promote pathological research in association with clinical investigation in the Philadelphia and Baltimore periods. Thus his Goulstonian Lectures on malignant endocarditis[16], based entirely on autopsies performed in Montreal, contained the first comprehensive account in English of the disease and are largely clinical and pathological, but not experimental. He suggested that malignant endocarditis was invariably of bacterial origin ; he stained the organisms in the tissues and made a few inconclusive inoculation experiments ; but left to others the task of bacteriological investigation of this malady.

One of Osler's last pieces of microscopical investigation was his confirmation in 1886 of Laveran's discovery of the malarial parasite[17]. It was due to Osler's prompt appreciation of this discovery that the prevalent theory of a mysterious nocturnal 'miasma' was overthrown in the United States, and in his Baltimore Clinic, a few years later, he insisted that no diagnosis of malaria should be made without a microscopic examination of the blood. His hæmatological studies led him to take a special interest in diseases of the blood, and he described in 1902 "cyanosis with polycythæmia"[18], since known as 'Osler's disease'. A hereditary malady characterized by multiple telangiectases associated with hæmorrhages[19] is also styled 'Osler's disease'.

Throughout his professional life, William Osler applied his scientific knowledge to the study of clinical disease and brought the laboratory to the bedside. His teaching in this respect has greatly influenced the progress of clinical medicine. He referred to this guiding star of his work in the following words : "To the physician particularly a scientific discipline is an incalculable gift which leavens his whole life, giving exactness to habits of thought and tempering the mind with that judicious faculty of distrust which can alone, amid the uncertainties of practice, make him wise unto salvation"[20].

SCIENCE OF THE AMARYLLIDS

THE American Plant Life Society, organised for the increase and diffusion of knowledge concerning plant-life, issues the year-book "Herbertia", which is devoted to the Amaryllids. Issues for 1946 and 1947 appeared together late in 1947 (from the Society, Box 2398, Stanford, California), and contain some useful papers of scientific interest. A detailed account of "the karyo-systematics of the sub-genus *Ajax* of the genus *Narcissus*" (Vol. 13, 1946) is contributed by A. Fernandes and Rosette Fernandes of Portugal. Of about eighteen species, fourteen are diploids, normally with $n = 7$. *Narcissus hispanicus* is constituted of diploid and triploid forms, *N. tortuosus* is triploid, and *N. bicolor* tetraploid. Fifteen somatic chromosomes are found in *N. asturiensis*, *N. minor*, *N. pumilus* and *N. pallidiflorus*. Since all the species have the same karyotype, this supports the idea of Baker (1888) that the group is a single, very polymorphic Linnean species. The different forms have arisen by gene mutation and polyploidy.

A useful description of narcissus disease symptoms and control is given by Charles J. Gould (Vol. 13, 1946), with several photographs. Perhaps the most interesting to British readers is a virus disease rather appropriately named 'decline', but also known as 'white streak'. A corresponding paper on insect and mite pests of narcissus by E. P. Breakey mentions the narcissus bulb fly, the lesser bulb fly and bulb mites, all of which are already known in Great Britain. It is usual to grow Amaryllids for their garden beauty, but M. J. Cox and M. M. MacMasters show (Vol. 14, 1947) that starch can also be prepared from the tuberous roots of *Alstrœmeria aurantiaca* and *A. chilensis*. Granules from the former are simple, but those from the latter have an unusual compound nature. Both give pastes which have similar characteristics to other root starches.

There are also shorter articles on all aspects of Amaryllid culture, breeding and classification.

JOHN INNES HORTICULTURAL INSTITUTION

FOR thirty-eight years, the John Innes Horticultural Institution has been carrying out detailed investigations in plant culture, genetics, breeding and other matters. 'J.I.' composts are now widely used and have perhaps done more than anything else to make the name of the Institution familiar to gardeners. The annual report for 1947, recently issued, gives the results of many continued researches. M. B. Crane has obtained a certain amount of resistance to pear scab, *Venturia pirina*, from crosses between the pear varieties Giffard and Conference. Rogues in tomatoes are shown by D. Lewis to appear most frequently when the plants are grown at high temperatures (26° C.). The same author has analysed seven X-ray induced mutations of the incompatibility gene of *Œnothera*. They do not confer complete self-compatibility ; but the work is being continued. K. Mather has investigated the three types of gene which affect heterostyly in *Primula sinensis*. The difference of morphology and physiology between pin-eyed and thrum-eyed flowers is determined by the major genotype, and finally adjusted by the polygenotype. Miss A. Vines has studied breeding system and genetic isolation in *Antirrhinum*, and A. J. Bateman has estimated the effect of various isolation systems on contamination in seed production.

Work on plant improvement by crossing has been carried out for uniform coloration of fruit in tomato (G. M. Haskell), and for combining the dwarf habit of *Phaseolus vulgaris* with the extended inflorescence of *P. multiflorus* (L. G. Wigan).

The Cytology Department, under Dr. C. D. Darlington, director of the Institution, has worked on the effect of cell gradients in controlling the development of nuclei in the pollen grain. The occurrence of dwarf pollen has engaged the attention of L. F. la Cour, who discusses the relative merits of segregation and differentiation as a cause. Further studies include the effect of X-rays on meiosis, and chromosome breakage by temperature shock. An interesting development in the Garden Department, under W. J. C. Lawrence, is the effect of artificial lighting on the yield of tomato plants. Daylight fluorescent tubes lit for 6 hr. a night for the first twenty nights after germination resulted in a much heavier yield of fruit, particularly in the first three weeks of picking.

The Institution is still carrying out its long-term programme of removal to Bayfordbury, Hertford; but it is expected to be some time before the transfer is complete.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Research Officer at the Division of Industrial Chemistry, Melbourne—The Chief Scientific Liaison Officer, Australian Scientific Research Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 1765 (September 4).

Head (male) of the Poultry Department at the Ulster Dairy School (for girls), Cookstown, Co. Tyrone—The Establishment Officer, Ministry of Agriculture, Stormont, Belfast (September 4).

Lecturer in Agriculture and Farm Bookkeeping, and a Lecturer in Agriculture, Farm Implements, Building Construction, etc., at the Cheshire School of Agriculture, Reaseheath—The Director of Education, County Education Offices, City Road, Chester (September 4).

Instructresses (2) in Dairying and Poultry-keeping—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh 8 (September 4).

Chemist, and a Physicist—The Secretary, Hosiery Research Council, 4 First Avenue, Sherwood Rise, Nottingham (September 4).

Research Physico-chemist at the Research Institute of the Foot-and-Mouth Disease Research Committee—The Director, Research Institute, Pirbright, Surrey (September 4).

Demonstrator in Chemistry and Biochemistry with a special interest in Physical Chemistry—The Dean of the Medical College, St. Bartholomew's Hospital, West Smithfield, London, E.C.1 (September 4).

Lecturer in the Engineering and Mining Departments to take Electrical Technology and Mechanical Engineering with mining qualifications—The Registrar, University College, Cathays Park, Cardiff (September 4).

Lecturer in Entomology, an Agricultural Economist, and an Assistant Agricultural Economist—The Registrar, The University, Bristol 8 (September 4).

Lecturer or Assistant Lecturer in Physics—The Principal, College of Technology, Manchester (September 6).

Biologist (Technical Officer) as Head of the Biological Section of the Technical and Scientific Register—The Ministry of Labour and National Service, Appointments Department, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting G.351/48A (September 6).

Mechanical Engineer (Ref. C.528/48A), and a Standards and Co-ordination Engineer (Ref. C.529/48A), at the Atomic Energy Research Establishment, Harwell—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting the appropriate Ref. No. (September 6).

Agricultural Economist (male)—The Registrar, Wye College, Wye, Ashford, Kent (September 7).

J. G. Graves Medical Research Fellowship for full-time research in some branch of medical science approved by the Faculty of Medicine—The Registrar, The University, Sheffield 10 (September 11).

Assistant in the Engineering Department, London H.Q.—The Director, Personnel Department, British Council, 3 Hanover Street, London, W.1 (September 11).

Editorial Assistant (with degree in physical science with bias towards physics and mathematics) to the Royal Society—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting A.270/48A (September 11).

Lecturer in Anthropology with special reference to India—The Secretary, School of Oriental and African Studies, University of London, London, W.C.1 (September 11).

Senior Lecturer in Mathematics at the New England University College, Armidale, New South Wales—The Secretary, Universities Bureau of the British Empire, 32 Woburn Square, London, W.C.1 (September 15).

Assistant Bacteriologist (with an Honours Science Degree in Bacteriology), and an Assistant Biochemist (with an Honours Degree in Science and special experience in Biochemistry), to the Northern Regional Hospital Board—The Secretary and Administrative Medical Officer, Raigmore Hospital, Inverness (September 15).

Professor of Botany at Fouad I University, Cairo—The Director, Egyptian Education Bureau, 4 Chesterfield Gardens, London, W.1 (September 15).

Assistant Lecturers (2) in the Department of Civil Engineering—The Professor of Civil Engineering, Queen's University, Belfast (September 15).

Research Officer in the Building Research Section, Melbourne—The Chief Scientific Liaison Officer, Australian Scientific Research Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 1547 (September 18).

Assistant Lecturer or Lecturer in Agricultural Economics—The Registrar, The University, Leeds 2 (September 22).

Experimental Officers and Assistant Experimental Officers at the Department of Atomic Energy, Springfields, Lancs, to carry out experimental work arising from the metallurgical development involved in the production of atomic energy—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting F.391/48A (September 25).

Principal Research Officer in the Microbiological Division of the National Chemical Research Laboratory, Pretoria—The South African Scientific Liaison Officer, Africa House, Kingsway, London, W.C.2 (September 30).

Fisheries Assistant and Naturalist (temporary) for research at the Marine Biological Station, Port Erin—The Registrar, The University, Liverpool (September 30).

Chair of Mechanical Engineering—The Registrar, The University, Leeds 2 (September 30).

University Lecturer, preferably with special qualifications in Fluid Dynamics, Atomic Physics or Algebra—The Secretary of the Appointments Committee, Trinity College, Cambridge (September 30).

Readership in Metallurgy in the Department of Coal, Gas and Fuel Industries—The Registrar, The University, Leeds (September 30).

Kennedy Chair of Mechanical Engineering at University College—The Academic Registrar, University of London, Senate House, London, W.C.1 (October 7).

Director of Research at the Hosiery Research Council's Research Station at Thorneywood House, Nottingham—The Director, National Hosiery Manufacturers' Federation, 104 Regent Road, Leicester (October 15).

Chair of Geology at King's College—The Academic Registrar, University of London, Senate House, London, W.C.1 (October 25).

Professor of Civil Engineering, and a Professor of Electrical Engineering, at the Thomason College of Engineering (Roorkee University)—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2, quoting No. 412A (October 30).

Chair of Zoology at King's College—The Academic Registrar, University of London, Senate House, London, W.C.1 (November 1).

Fisheries Officers in Malaya—The Director of Recruitment (Colonial Service), Sanctuary Buildings, Great Smith Street, London S.W.1.

Tsetse Fly Ranger by the Government of Nyasaland, for tsetse fly survey and reclamation duties—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.N.21794/3F.

Scientists (*a*) with research and practical experience in Coal Mining, Coal Preparation and Carbonization and Briquetting (Ref. TT/70), and (*b*) to take charge of the Chemistry Laboratories and with all-round research experience with specialist knowledge in Coal Chemistry Analytical work, Metallurgy or Coal Tar (Ref. TT/71)—The National Coal Board, Establishments (General) Branch, Hobart House, Grosvenor Place, London, S.W.1, quoting appropriate Ref. No.

Superintendent of the Scottish Laboratories, involving responsibility for all chemical, mechanical and micrographic testing and for advisory service to Scottish members—The Secretary, British Cast Iron Research Association, Alvechurch, Birmingham.

Geologists for research on concentration of iron ore (*a*) with special knowledge of petrology or sedimentary rocks, (*b*) with experience of ore dressing problems—The Personnel Officer, British Iron and Stee Research Association, 11 Park Lane, London, W.1.

Research Assistant in Statistics (preferably with Degree in Mathematics)—The Lecturer in the Design and Analysis of Scientific Experiment, 91 Banbury Road, Oxford.

Senior Engineer in the Land Drainage Branch of the Public Works Department, Sierra Leone—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Lecturer in Radio Engineering—The Clerk, Northern Polytechnic, Holloway, London, N.7.

Visiting Demonstrator in the Department of Bacteriology—The Secretary, King's College of Household and Social Science Campden Hill Road, London, W.8.

SECOND THOUGHTS ON UNIVERSITY EXPANSION

THE almost simultaneous publication of the Nuffield College Statement "The Problem Facing British Universities" and the symposium on "Entry and Careers" in *The Universities Quarterly* for August provides valuable material for further discussion on the expansion of the universities. The former Statement brings together much useful statistical information as well as collecting in its chapters on the demand for university graduates estimates of intake to the professions which are not otherwise conveniently accessible. Moreover, in the further chapter on the flow from the schools the Statement does something to meet a point made by Dr. Eric James, high master of the Manchester Grammar School, at the British Association conference on "The Place of Universities in the Community" last year, as well as to supply a factual background to Dr. J. F. Mountford and Mr. James Hemming's contribution to the symposium. Indeed, the Statement contains so much factual information that it is not easy to see the wood for the trees, and the conclusions seem to indicate that the members of the Nuffield Committee have not been entirely sure of themselves for that reason.

The Statement sets out in the first place to survey the chief demands made on universities, and after reviewing those made by the organised professions and other regular occupations which rely for recruitment on university graduates, including the demand for admission from overseas students, which is expected to be strong for some time, it considers the extra-mural work of the universities and the position of the higher technical and other specialized institutions. While the Statement does not commit itself to any quantitative estimate of the extent of university expansion, the Committee regards a permanent expansion as probable and appears to be satisfied that there is little risk of the large number of graduates failing to find employment. On the other hand, it formed the opinion that in the aggregate present demands are probably exaggerated, and that if the demands are pressed separately and dealt with piecemeal without consideration of their interrelation and aggregate effect, there may be real danger that legitimate but sectional needs will be met to the neglect of other needs of greater importance to the maintenance and development of the universities.

The Statement is thus first and foremost a challenge to fresh thought about the purpose and functions of a university, and as a result of that thinking to determine principles by which sound decisions can be made in balancing new claims against existing duties or one new claim against another. The Nuffield Committee does not, it is true, go very far in its analysis. It insists that in the first place there must always be an element of general education or culture in the teaching a university gives, and that, in the second place, this teaching must be given by scholars and men of science who are themselves working at the frontiers of knowledge. A university must maintain a reasonable range of studies, and not allow its desire to meet any one claim to turn it into a specialized institution restricted to serving the needs of a single profession or field of research, nor must any aggregate demands for teaching be allowed to deflect its staff from pursuing their own studies and research. The Committee observes here that it is at least a possibility that in the endeavour to give everyone whatever he wants, the universities may end by giving nobody what he requires.

The two chief suggestions made in the Statement to relieve the universities in meeting the immediate and short-term problems of expansion will be discussed in due course. The Committee recognizes that there is no satisfactory solution to the problem of meeting under present conditions the sudden expansion in the demands made on the universities. Its suggestion as to the extension of the extra-mural work of the universities has a bearing, however, on the long-term problem of expansion with which the universities are simultaneously faced.

The Statement suggests that universities which are adequately staffed might extend the opportunities which they offer to part-time students already qualified by previous education by allowing such students who are prevented from full-time residence to spread their study over a longer period than the usual full-time period, and by the provision of short special courses of the refresher type for those who can only come for a short period. The emphasis thus placed on the extra-mural and regional responsibilities of the universities is welcome: no short-term policy even which severely restricted the discharge of such responsibilities could wisely be accepted. Nevertheless, the Statement does not make it clear how the continuance or extension of such functions will contribute to ease either the short-term or long-term expansion. Like the question of size, on which also the Statement briefly comments, these functions appear to be mentioned chiefly as essentials to be kept in mind in deciding the exact purpose and functions of the universities.

Where the Statement is most disappointing is not so much in not indicating the Committee's own conception of a university and the precise purposes and functions it should serve, as in the absence of any constructive suggestion as to how we are to formulate such a conception or definition or to deal with those questions of geographical distribution of universities and the distribution of university resources among different projects where some co-ordination and concerted effort are essential. It rejects the proposal for a royal commission on universities as imposing a further burden on university administrators and teachers who are already overtaxed, without offering much hope of any kind of an early solution of problems. But to the crucial question whether the universities and the present University Grants Committee are competent to effect such a survey of needs and reforms or whether an external agency is required it gives no answer; but merely states the arguments for the alternative courses.

These arguments are admirably put, but what is required at the moment is decision. The Nuffield College Statement makes curious reading on this point, with Lord Lindsay as one of the signatories. Lord Lindsay's plea in the House of Lords debate on the universities in May of last year for a comprehensive review of the situation as a whole by some body other than the University Grants Committee is perhaps the most convincing argument yet advanced, not for the departmental committee which he suggested, but for the comprehensive and comparative survey which a Royal Commission alone could be expected to make.

However right it may be to hesitate to designate men and women for such a task when our ablest administrators are already often seriously overworked, that exigency is no more valid a reason for not examining the whole problem at the highest level than it is for not carrying out that survey of the machinery of government at the Cabinet and ministerial level for which the Select Committee on Estimates called in a recent report. Failure to conduct either survey may, and almost certainly will, involve waste of man-power at all levels immensely out of proportion to that involved in conducting the survey. So far as the universities are concerned, the brake on expansion imposed by the building situation may well afford the necessary breathing space for such a survey if a prompt decision is made as to the instrument to be used to conduct the survey. Nor need, it might be added, a royal commission, as opposed to the University Grants Committee, or some sub-committee of that body, employ the time of more than a very few of those actively engaged in university administration or teaching. Not only is there a sufficient reservoir of able minds with some experience and understanding of university problems, but much of the information is already being accumulated by various independent means or bodies; these activities and results require bringing together in a composite picture upon which judgment and decision can be based.

Except in respect of science students, where the analysis of available figures is somewhat limited, the Nuffield College Statement provides a fairly detailed comparison of the expansion of the different universities and university colleges in 1945–47 as compared with the situation before the War. The most interesting feature of the symposium in *The Universities Quarterly* already noted is the reference to a number of inquiries already conducted by the Technical Personnel Committee set up by the Ministry of Labour and National Service under the chairmanship of Lord Hankey, some of which do not appear to have been published. The quotations from these reports are complementary to the information in the Nuffield Statement and help to fill in some of the gaps that exist in our knowledge of the present situation and the probable demand for particular classes of graduates.

It is well known that while in the autumn of 1947 the number of students in British universities had risen from the pre-war 50,000 to roughly 77,000, the number of science students had practically doubled and stood at 14,500. As regards arts students, 'if the student population remains at about 80,000, there are expected to be about 12,000 graduates in each year from 1951 as against 7,000 before the War. In spite, however, of this increase in the number of science students, no substantial increase in the output of graduates available for employment outside the universities is expected before 1950. Thereafter there should be a rapid increase to about 5,000 each year or double the pre-war output. The first substantial increase in graduates in technology will likewise not be effective industrially until 1950, owing to the demands of military service, but by 1951 the output should be 3,400 each year as compared with 1,500 pre-war.

These are figures of which not only the universities but Government Departments as well as the universities should take careful note, and they should certainly guide the Advisory Council on Scientific Policy in considering the distribution or re-distribution of scientific man-power. Moreover, when the development plans of both large and small firms are already impeded by their inability to secure the recruits they require for research and production, with all that involves for industrial recovery and export, the situation disclosed by Mr. L. E. Ball in regard to particular categories is disturbing.

Mr. Ball, the secretary of the University of London Appointments Board, states in this article that there are at present sufficient chemical appointments vacant to absorb all new graduates in chemistry up to 1949 and that demand appears to be increasing steadily. Again, the Technical Personnel Committee, according to Mr. Ball, estimates the demand for chemical engineers for the next five years to be 240 a year as compared with a present annual output of less than 100. The reduction in new construction has, however, reduced the demand for engineers, and in engineering generally it seems that supply is in excess of demand.

This report from the Technical Personnel Committee would seem to be one of three reports which, according to Mr. Ball, have already been issued. One relating to mycologists and microbiologists, stated to have been issued in July 1947, indicated that the present output of microbiologists and mycologists is adequate and that a large expansion is not justified. A similar statement has been made of architects, and generally such inquiries as have been made by the Ministry of Labour and bodies like Political and Economic Planning indicate that most of the professional organisations do not expect any large increase in numbers once their war-time gap has been filled. Mr. Ball, however, expresses the hope that other reports dealing with chemists, biologists and physicists will come from the Technical Personnel Committee without delay, and the figures for physics honours students quoted by Sir Lawrence Bragg were presumably collected for this Committee.

Sir Lawrence Bragg points out that the honours physics schools of our universities are now producing about 600 graduates annually in place of a little more than 200 before the War, and returns from the universities indicate that this number is likely to be maintained for the next few years. Of these graduates in 1947 some 31 per cent entered careers in university or government research as against 29 per cent in pre-war years, 19 per cent entered industry in place of 30 per cent, and only 12 per cent took up a school teaching career as against 29 per cent before the War.

These figures are no less disturbing than those for chemistry graduates, and although the symposium in *The Universities Review* does not give any clear idea of the magnitude of the university expansion at which we should aim, it reinforces the argument for a comprehensive review of the whole situation and points also to the importance of associating industry with this review. Even from a short-term point of view the distribution of scientific man-power needs to be watched closely or there may be as serious repercussions on the flow of students to the universities for science courses as through the inability of industry to recruit the scientific workers it needs now so imperatively for research and production. Moreover, it seems clear also that only with the help of industry can serious unemployment among those who have graduated in arts be avoided during the next four years. Only in industry can openings be found for a considerable surplus over those who can find places in teaching and the professions, and there is real call for business men and industrialists to re-examine their recruiting policy and reconsider their needs for competent managers at the lower salary levels as well as at the directorate levels

At the entry side, both Sir Lawrence Bragg and Mr. J. Hemming direct attention to the question of quality. There seems to be little doubt that Great Britain's reserves of innate intelligence are sufficient to provide annually another 50,000 students of as high mental ability as those attending before the War. There is some doubt as to whether all those students would be forthcoming with the other specific aptitudes, including cultural standards, to make the most of a university life. Mr. Hemming is hopeful but Sir Lawrence is dubious. He has formed the impression that while we have not been missing many first-rate people, we are admitting to honours courses too many who would have profited more by training in much less ambitious courses.

The question of selection of students will be brought to the fore when the Working Party in State Scholarships and Major Awards reports to the Minister of Education shortly. The question of the cost of university education on which Mr. P. F. Vowles just touches in the concluding article in this symposium is bound to become increasingly prominent in discussions on university expansion. However fully we may subscribe to the belief that university education is an investment, it must be recognized that both the universities and the State have a duty to see that the considerable sums involved are wisely spent. It has been estimated that it costs £3,000 to provide a student at Cambridge with a three-year course. Even if his parents are prepared to pay £300 towards it, £2,700 has still to be found from public or university funds. Expenditure at the provincial universities is much less, but neither there nor at Cambridge can the nation as a whole afford to spend such sums on individuals who possess neither the brains nor the personality to profit from them.

Neither the Nuffield College Statement nor the symposium in *The Universities Review* does much more than indicate the range of problems to be solved and the imperative need for dealing with them as a whole and not piecemeal. Both challenge creative thinking about the purposes and functions of a university. Both indicate the urgent need for decision as to the body to whom that overall review is to be entrusted and for swift action as soon as the facts can be fully assembled and considered judgment made. It seems equally clear that if the nation's reserves of intelligence are to be trained and distributed to the best advantage, in that review must be joined the best minds that not only the universities but also industry and the nation as a whole can supply.

EVOLUTION IN MANKIND

A New Theory of Human Evolution

By Sir Arthur Keith. Pp. x + 451. (London: Watts and Co., Ltd., 1948.) 21*s.* net.

THIS book is the fruit of a long life of scientific work and meditation by a distinguished thinker with strong intuitions, trying to look towards a synthesis as yet seen 'through a glass darkly', and trying to make that vision clearer without limiting possibilities of its future adjustment. There is no attempt to force the facts to fit preconceived dogma, no riding of a pet theory to exhaustion.

The basic idea is derived mainly from Darwin, Romanes and Gulick. It is that isolated small, inbred groups are likely to diverge. This view is strengthened by the work of the geneticists, who show that in such a group dominant genes are likely to spread generally among the members, especially if they carry some character of value in the environment concerned. Defective genes may bring rapid extermination, especially if emphasized by close inbreeding.

Keith emphasizes the smallness of the hunter-collector groups in several environments; and he might have made more of the probability that in that stage of social-economic development, Britain is not likely to have had more than a few hundred people in scattered small groups. He directs attention very justifiably to the territorial bases of the little early group which he, in common with all other scientific observers, regards as a basal feature of our heritage from prehuman ancestors. Society is not primarily a human construction, and whatever we may say about social elaborations, they are, as it were, shoots on a prehuman trunk. The territorial basis may be a hunting-range, including perhaps a water supply and so on; the group will typically resent intrusions of strangers and will combine to defend the territory. Here we have Spencer's code of amity within the group and code of hostility outside it, both features of the ethical make-up of mankind, the disharmony between which is our permanent problem. But Keith is concerned with the fact that the code of hostility promotes inbreeding and differentiation, in language and custom as well as in physique; and, at an early stage, the more diversity the less interbreeding. Differences of language and custom are thus factors of isolation which he thinks may be more powerful than mountain or desert belts.

The small group has tended to remain poor, and larger associations of groups have come into existence, with decreasing uniformity in physique, but sometimes enforced uniformity in language and custom Inbreeding, dangerous as well as sometimes useful, i less and becomes less still when one group conquer another, and the conquerors, mainly young men, tak to themselves the girls of the conquered people. The larger and more complex group has more to defend and around this gathers the emotion of patriotism this in turn promotes breeding within the group, so the self-conscious, patriotic group may differentiat itself, even physically, from others in the course of time. A tribesman, says Keith, is apt to transfer hi own emotions and impulses to his tribe or group, and we know the power of that group impulse, especiall in connexion with the code of hostility. Russe Wallace was the first to emphasize group-solidarit and the accompanying selection between groups as a factor of evolutionary differentiation.

Keith emphasizes fœtalization as a factor of evolutionary differentiation. The forehead and many other features in women are usually nearer the fœtal stage than those of men. Mongol features, so called including a low and retracted nasal bridge, an epicanthic fold over the upper eyelid and protuberant eyeballs, are fœtal and transitory in a proportion of Europeans, but durable in parts of Eastern Asia and among the majority of Hottentots. These resemblances are not necessarily indications of close genetic relationship.

It has seemed best to try here to give a fairly general picture of Keith's views. The book reviews many stages of human social, as well as physical differentiation and gives the author's considered opinions. He adheres, for example, to the view that the Piltdown skull and jaw belonged to one and the same individual, arguing against the opinion that they are of different species but not mentioning the bare possibility that the skull might be that of a female and the jaw that of a male.

Keith's idea of inbreeding groups as in process of differentiation leads him to think of them as possibly races in the making; but most groups of the presen time are heterogeneous and likely to remain so, and it might be better to use some term other than tha of race in this connexion.

The book is one for careful meditation, and is an interesting monument of a respected and beloved personality.

H. J. FLEURE

TOWARDS A MATHEMATICAL SOCIOLOGY

Mathematical Theory of Human Relations

An Approach to a Mathematical Biology of Social Phenomena. By N. Rashevsky. (Mathematica Biophysics Monograph Series, No. 2.) Pp. xiv + 202 (Bloomington, Indiana: Principia Press, 1947. 4 dollars.

IT is only in quite recent times that mathematical methods have been applied in the social science or, indeed, in those fields, such as psychology, wher the natural and the social sciences overlap. The use of mathematical-statistical methods in the handling of data, as in biometrics or econometrics, has developed rapidly in recent years. The employment o mathematics as a tool of analysis in the development of theory has been neither as general nor as successful Mathematical economics, like mathematical biology is taking its place in the general body of theory, and the time is ripe for extensions into other social sciences. What the author of this book attempts is a sketch of the possibilities of a mathematical sociology. He is where the mathematical economist or biologist was some decades ago, experimenting with alternative formulations and various types of simplification. He has a wider and more difficult field than the economist or biologist but; since his science overlaps with theirs, he can draw upon their experience.

I can give no more than a brief indication of the scope of the author's essay. He attempts a theory of the way in which classes or groups are formed, of their size and number. He considers the interaction of one group with another within the social structure and, in particular, the various kinds of conflict from economic exploitation to war. He develops the characteristics of individualistic as against collectivistic societies. He has a good deal to say on the dynamics of the growth and decay of groups; for example, the controlling power of a group, derived by inheritance from past generations, may become unstable. He finds that a rather general formulation involves complicated integral equations; but, by simplification of his models, he is able to proceed with differential equations and with ordinary problems of maximum and minimum.

The author would, I think, agree with me in stressing two aspects of his work. One is that he is experimenting with various mathematical formulations, most of which may not lead to anything fruitful. Even so, the work is not wasted. It is always useful to translate into mathematical terminology the different theoretical situations studied; in this case the growth and interactions of groups in the social structure. This serves, at least, to clarify the nature of the assumptions on which the theory rests and to distinguish sharply between the various possibilities.

The second aspect is that, eventually, any mathematical theory must be developed to the point where it can be put to the test with actual data and lead to prediction. The author's theoretical constructions are, he admits, crude and oversimplified descriptions of a modern society. But, if only for illustrative purposes, he ventures to introduce actual data from time to time to match against his theoretical results.

Against these merits must be set certain weaknesses, many perhaps inevitable in a pioneering study. I think the author has been ill-advised to publish his work in book form so early in its development. With more time, he might have shown greater discrimination in his selection of formulations for development; he might have cut out some weaker threads and tied up some of the stronger but loose ones. He is at his weakest where he analyses the economic aspects of social groupings. He admits that much of what he does must appear crude to an economist, but feels that his simple approach is necessary to "bring out the social aspect of the interrelation of economic classes" (p. 40). Perhaps so, but I feel that he can only say this after a close examination of the work of mathematical economists. His references make it clear that he has not read widely in this field. He is much influenced by two or three writers, particularly G. C. Evans (referred to throughout as G. E. Evans), whose work dates back to the 1920's and early 1930's. He displays no knowledge of later work, particularly in economic dynamics, which would be of more help to him. He would find, for example, that mathematical economists first followed physicists in using differential equations but afterwards turned to difference equations as more appropriate to their subject, and (incidentally) discovered them to be just as easy to handle. His assertion that "no successful application of mathematics to social phenomena has been made" (p. iv) is not true of at least one branch of the social sciences.

R. G. D. ALLEN

THE UNIFORM CALCULUS

A Text-Book of Mathematical Analysis

The Uniform Calculus and its Applications. By R. L. Goodstein. Pp. xii + 476. (Oxford: Clarendon Press; London: Oxford University Press, 1948.) 30*s*. net.

THE problem of presenting the infinitesimal calculus to schoolboys and university students who seek to acquire a knowledge of it for applications in other fields is notoriously difficult. Methods based upon geometrical intuition lack rigour and to the thinking student produce an impression of mystery. Methods based on a rigorous theory of real numbers are suited only to the student who is to become a mathematical specialist.

Dr. Goodstein proposes to avoid the difficulty by a simplification of the calculus itself, by restricting his treatment to functions which possess uniform differentiability. The foundation-stone is the notion of a convergent sequence of terminating decimals, which is then extended to convergent sequences the terms of which are endless decimals. The notation $0(r)$ is used to signify any number which is zero to r places of decimals, that is to say, a number the positive value of which is less than $1/10^r$. A function $f(x)$ is said to be uniformly differentiable in the interval (a,b) if we can find functions $f'(x)$ and $n(r)$ such that

$$\frac{f(X)-f(x)}{X-x} = f'(x) + 0(r)$$

for any numbers X, x in (a,b) which satisfy $X - x = 0(n(r))$.

The (uniform) derivative $f'(x)$ thus defined exists for all the usual elementary functions which the student is likely to encounter, in particular for the circular and exponential functions.

It is then proved that a uniform derivative is a continuous function, and that a function uniformly differentiable in (a,b) is continuous in (a,b).

On this basis, and with suitable definitions of integrals, the uniform calculus is built up in such a manner that the ideas can be appreciated by a student who has only a modest knowledge of arithmetic and algebra.

The first eleven chapters contain all the calculus that is needed for the ordinary and advanced papers of the higher school certificate examinations. The whole book covers the calculus syllabus for the general honours degree of London and provincial universities and the London special degree.

The demonstrations are lucid and often original, and the student should profit by the examples of technique so well illustrated in every chapter. The standard functions e^x, $\sin x$, $\cos x$ are defined by their expansions in power series and are introduced in a natural and satisfying manner.

The author has purposely given no diagrams in order to prevent the possibility that geometrical intuition may disturb algebraic reasoning. One might, however, expect a certain amount of sales resistance from a certificate student to the statement that the area bounded by a simple closed curve is

$$\left| \tfrac{1}{2}\int_{t_0}^{t_1} (xy' - x'y)dt \right|,$$

with the added note that a rigorous proof belongs to the theory of double integrals and is postponed to Chapter 17.

The book is certainly a contribution of outstanding merit to the very few serious efforts which have been made to present limiting processes to the student at a level which he can readily understand, and which at the same time will leave him nothing to unlearn at a more advanced stage. The book contains more than four hundred worked examples.

L. M. MILNE-THOMSON

SCIENCE IN RELATION TO HISTORY

Science and its Background

By Lieut.-Colonel H. D. Anthony. Pp. ix + 304. (London: Macmillan and Co., Ltd., 1948.) 10*s.* 6*d.* net.

THERE are many ways in which authors have dealt with the history of science. This important subject can appear as a plain chronology of scientific development without any account of its relations to contemporary thought, it can take the form of a series of 'great lives' given with anecdotal treatment, or it may trace the parallel evolution of philosophic thought at each stage. The work here reviewed is eclectic in its methods: it envisages the story of science through history, and, moreover, a history which takes account, as all histories should, of human development and the evolution of social institutions. The author, a former grammar school headmaster, is the chief inspector of education in the British Army, and if the contents of the book are an indication of what is done in adult education in the Services and elsewhere it is a happy sign of the times. In its three hundred pages the book deals with many subjects. The author has succeeded in being succinct without being superficial by a careful selection of the most important topics for his purpose.

The form of the book is original in its layout and in the grouping of the material. The great movements in the advance of scientific knowledge are considered under the following headings: the beginnings of science in the "Rivers Period", the Mediterranean Period (Classical and Medieval), the Atlantic Period (Renaissance to Modern), the World Period (International Conflict and World Co-operation).

The main need in the teaching of science at present is not an improvement in practical techniques, nor of further specialist subdivisions of the science subjects. The dichotomy between what so often passes in school and university for science and culture is a matter which exercises the minds of many mid-twentieth century thinkers. There is an urgent need for seeking a new synthesis, and as a guide the book here reviewed would make a good introduction. The author is always fair, and evinces no emotional, political or religious biases which make a mockery of the scientific spirit and mar so many works on the relations of science with other forms of human activity.

The book should be read by every sixth-form pupil, whether of arts or science. For the lay-reader requiring a short, readable and accurate account of the growth of science in its human context, it is difficult to see how it could be improved.

The production of the book in general and its pictures and time-charts in particular reach a high standard.

W. L. SUMNER

INSECTICIDES AND FUNGICIDES

A Catalogue of Insecticides and Fungicides

Vol. 1: Chemical Insecticides. Compiled by Prof. Donald E. H. Frear. (Annales Cryptogamici et Phytopathologici, Vol. 7.) Pp. xii + 204. (Waltham, Mass.: Chronica Botanica Co.; London: Wm. Dawson and Sons, Ltd., 1947.) 6.50 dollars.

THERE is a large and expanding literature concerned with the control of insect pests by the use of chemicals, derived either from plants or synthesized in the laboratory. The number of compounds tested for this purpose is already very great, and the relevant information is scattered through many original papers. Many workers in this field undoubtedly have references to much of it filed away, but it is only the relatively widely used compounds that are essentially borne in mind when particular problems arise. Not only so, but in all branches of human knowledge the recording and indexing of information demands great expertness if it is to be readily available. Prof. D. E. H. Frear has obviously applied considerable expertness and a vast amount of labour in accumulating and arranging this catalogue of compounds, tested or employed at one time or another for the control of insect pests, with the appropriate references to original or review papers and to the patent literature.

The compounds are not arranged alphabetically, and before the catalogue can be used with advantage it is essential that the coding system employed be studied with some care and mastered. This requires a certain amount of knowledge of chemical terminology; but briefly, a code number is assigned to each constituent group of a compound, which is specified by arranging these in consecutive order, beginning at the lowest. Thus D.D.T. is expressed by a number, 855–952–1011, which was turned up quite rapidly, only to find no references to the literature were given; the author, however, explicitly rules out from his survey the better-known insecticides for which review papers and monographs are in abundant supply. It is for the less-known compounds that this record will be of use to the research worker. It is, perhaps, natural that the greater proportion of the references are to papers in American journals and to the bulletins of American research stations, but if this experiment succeeds, doubtless the range will be made wider in future editions.

It is to be regretted that the alphabetical index of the compounds has been relegated to the end of Volume 2, since if insecticides and fungicides deserve separate volumes—which they do—they should each have had their own index. It would not only have made this volume of greater value to those investigators whose knowledge of chemistry might be deficient, but also it might have made the array of facts in the book more rapidly accessible to others.

CENTENARY OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

By Dr. F. R. MOULTON
Administrative Secretary

FROM September 13 until September 17 the American Association for the Advancement of Science will hold in Washington, D.C., the centennial celebration of its founding. It was born in Philadelphia, Pennsylvania, on September 20, 1848.

The A.A.A.S. (to use the customary abbreviation of the present time) owes much, particularly in its earlier years, to the pattern set by the British Association for the Advancement of Science, which was organised in 1831. There were still earlier scientific societies in Great Britain and also in the United States, but they were somewhat different in character. The American Philosophical Society of Philadelphia was formally organised by Benjamin Franklin in 1743, and the American Academy of Arts and Sciences was granted a charter in Boston in 1780. The first attempt at establishing a truly national scientific society in America was the launching in 1816, under political sponsorship, of the Columbian Institute for the Promotion of Arts and Sciences. It flashed like a meteor and soon disappeared. Some years later, in 1840, the National Institution for the Promotion of Science was established by an Act of Congress. In 1844 it held a meeting at which John Tyler, then president of the United States, delivered the opening address. Government officials of high rank served as chairmen of the scientific sessions, at which forty-three papers were presented. The Institution never held another meeting.

A few years earlier, in 1837, Dr. John Collins Warren, of Boston, had attended a meeting of the British Association. It impressed him so favourably that upon his return to America he actively began to promote the establishment of a similar society in the United States. The failures of grandiose plans on one hand, and the limitations and weaknesses of small special societies on the other, directed the attention of American men of science to the founding of a scientific society national in scope and embracing all the sciences. This culminated on September 20, 1848, in establishing the American Association for the Advancement of Science, with an initial membership of 461. At the first meeting about thirty papers and oral communications were presented before the "Section of Natural History, etc.", and about as many before the "Section of Physics, etc.", the two subdivisions of the Association at that time.

The first period in the existence of the A.A.A.S. extended from its founding in 1848 until the outbreak of the Civil War between the northern States and the southern States, in 1861. In this interval of fourteen years thirteen meetings were held in different cities in the eastern part of the United States, and one was held in Montreal, Canada. The two original Sections of the Association were gradually divided into more specialized fields. The membership varied from the initial 461 in 1848 to a maximum of 1,004 in 1854.

In 1861 the Civil War broke out, and for five years the A.A.A.S. held no meetings, it elected no presidents or other officers, it issued no publications, and memories of its earlier meetings were dimmed. However, a meeting was held in 1866; but it was not such a meeting as earlier ones had been. The attendance was small, the papers presented were few, and the membership of the Association had declined below that with which it started. The conditions prevailed, generally, for about a decade, or until 1878.

In 1878 the membership of the Association was 962; in 1888 it had increased to 1,964, and it remained at about that level until 1900. Members of the A.A.A.S. were at its beginning and always have been on an annual basis, their dues being paid but once a year. Initially the dues were 1 dollar a year, but increased to 2 dollars in 1851, to 3 dollars in 1874, and finally to 5 dollars in 1920. Beginning with 1900 each member received with his membership a subscription for the weekly journal *Science*, and since 1915 a subscription for either *Science* or *The Scientific Monthly*. At the beginning of this calendar year (1948) the annual membership dues, including a subscription for either of the two journals, became 6.50 dollars a year.

An evolution in the structure and functions of the A.A.A.S. began in the closing decades of the nineteenth century and has continued until the present time. With the progressive specialization in science, the number of sections of the A.A.A.S. steadily increased. As their memberships grew they gave rise to the organisation of special societies—in mathematics, physics, geology, botany, etc. Many of these societies grew rapidly, and their memberships increased to such an extent that it became desirable for them to meet separately in order to obtain adequate accommodations in any American city. In a sense these developments appear to be the reverse of the integrations of science that were achieved when the Association was founded. But integrations of the sciences consist of something more than simultaneous meetings. The interrelations among them have been preserved by maintaining fifteen sections of the A.A.A.S., covering broadly all the principal sciences, the joint programmes of which with one another at the Association's meetings provide the cross-fertilization of ideas so important for vigorous scientific progress.

The outcome of this evolution in the organisation of American science has been a federation of co-operating scientific societies—the A.A.A.S. and its 207 affiliated and associated societies, the combined membership of which now totals several hundred thousands. Each of the 120 affiliated societies has either one or two representatives on the Council of the Association, who together constitute a large majority of the Council; the 87 associated societies are not represented on the Council. The affiliated and associated societies pay no membership fees or dues to the Association or fees for participating in its meetings. The harmony and co-operation of these many scientific societies in advancing science and human welfare present an inspiring example in a contentious and disordered world. It is the purpose of the A.A.A.S. to co-operate much more widely in the future with similar scientific societies in other countries and continents.

Now turning from a brief sketch of the evolution of the plans and ideals of the Association, the statistical story will be resumed, for it is the combination of both the principles and the practices of an organisation that measures its success. Membership statistics of the Association during its first half-century have been sketched. In 1900 the total membership of the Association was 1,925. In that year the weekly journal *Science*, owned and edited by Dr. J. McKeen Cattell, became the official publication of the Association. By 1908 the membership had become approximately 8,000, and it remained about the same until the close of the First World War, after which it increased rapidly for a decade. It exceeded 15,000 in 1928 and 18,000 in 1938. Now it exceeds 40,000.

There has been a geographical expansion of science, as well as a great increase in the number of men of science, in the United States. In 1916 the Pacific Division of the Association was organised by members of the A.A.A.S. who lived in the great and now populous States on the Pacific coast, about three thousand miles from the large cities in the East and two thousand miles from those in the Middle West, the regions in which meetings were generally held. In 1920 the South-western Division was similarly organised for the convenience of members who live in the south-western States. These Divisions of the Association are wholly autonomous in the election of their officers, the organisation of their annual meetings, and their relations with other scientific societies in their respective areas. The Pacific Division now has more than 4,600 A.A.A.S. members and the South-western Division nearly 800.

Perhaps the most effective way of describing the current policies and activities of the A.A.A.S. is to present a few statistics of the meeting that it held in Chicago during December 26–31, 1947. Although registration at the meetings of the Association has not been generally required, there were 4,940 registrants at the Chicago meeting, each of whom received a general programme. There were, in addition, several thousand persons for whom programmes were not available. As an illustration of the number of men of science at the meeting from a limited field, the official tabulated attendance at the annual "Biologists' Smoker" was 5,575—substantially greater than the total registration from all fields.

There were registrants at the Chicago meeting from every one of the forty-eight States, and also from Alaska and Hawaii. There were seventy-three registrants from Canada, twenty-eight from India and fourteen from China. There were 105 registrants from California, about 2,000 miles westward from Chicago, and 102 from Massachusetts, about 1,000 miles in the opposite direction.

A total of 2,019 papers were on the programme, of which 1,809 were presented orally, 46 consisted of demonstration and informal discussions, and 164 were read by title only. They were distributed among 340 sessions, the maximum number held simultaneously being 41.

It should not be assumed from the large number of men of science attending the "Biologists' Smoker" that the meeting was dominated by biologists or by scientific workers from any other particular field. Nor should it be assumed that the number of men of science was small from the fields in which there are large special scientific societies (the American Chemical Society, for example, or the American Medical Association), which hold their own large meetings quite independently of other scientific societies. At the Chicago meeting of the Association 4,288 registrants recorded their fields of specialization, in part, as follows: fields in which the special societies meet with the A.A.A.S.—zoology (822), biology (498), botany (903); fields in which the special societies hold independent meetings—chemistry (678), physics (296), medical sciences (354), agriculture (176), education (100).

As a consequence of the large attendance at the Association's meetings of specialists from every field of science, it is possible to organise and hold joint symposium programmes on subjects that are not limited by the usual boundaries of the various sciences.

An important feature of the Chicago meeting of the A.A.A.S. last December was the address of Dr. James B. Conant, retiring president of the Association and the president of Harvard University, entitled "The Role of Science in Our Unique Society". There were also ten scholarly addresses by retiring vice-presidents of the Association which in general were surveys or summaries of the fields of science of the Association's sections of which they were the respective chairmen.

In addition to these official programmes, there were seven sessions for special lectures or discussions of various aspects of the role of science in human affairs. Finally, there were fifty symposia on broad sectors of science of high current interest and importance.

As the present officers of the Association look back over the century of progress in organised American science made by their predecessors they have only feelings of gratitude and admiration for the high ideals which moved them and the success which crowned their efforts. As the present officers look with anxiety toward the future they can only say (to paraphrase the closing words of Milton's "Paradise Lost") that all the world is before them and Providence their guide. To paraphrase the opening invocation to "Paradise Lost", they can only say to the Heavenly Muse, what in us is dark, illumine, what is low, raise and support, that we may rise to the height of the great opportunities before us and justify our confidence in the powers of science to improve the lot of man.

ANTIBIOTIC ACTIVITY OF GROWTH-FACTOR ANALOGUES*

THE most striking reactions associated with the growth of micro-organisms are synthetic ones, particularly those concerned with protein synthesis. The synthesis of each compound is a stepwise process, each step being catalysed by an enzyme; if the necessary enzyme is in some way inhibited or has been lost during evolution of the organism, then growth will be slowed down or stopped unless the product of the reaction in which that enzyme was involved is now provided in the external environment. When the synthesis of a compound essential for growth is impossible through natural loss of an enzyme system, then that compound becomes for the organism a 'growth-factor'. By this term it is not meant to imply that the compound in question is not essential for those organisms which do not require it to be present in the external environment; all growth-factors investigated have been shown to be synthesized by a wide variety of organisms which do not require them pre-formed and, where these are known, to have the same functions as in the more exacting organisms. Thus it seems justifiable to consider all growth-factors as 'essential metabolites' and to regard the differences in requirements for them as differences in synthetic ability of the organisms investigated. On this basis, interference with the functioning or further utilization of the essential metabolite would produce the same metabolic lesion in those organisms which are able to synthesize it as already exists naturally in those which are not.

---

* Based on a discussion held at the Royal Society on June 17. There took part in the discussion, which was opened by Sir Paul Fildes, F.R.S., Dr. D. D. Woods, Dr. H. McIlwain, Dr. T. S. Work, Dr. H. N. Rydon and Dr. F. L. Rose; Dr. J. Walker, Dr. A. Albert and Prof. M. Stacey also contributed.

The concept of 'substrate competition' was already well established at the time that the mode of action of the sulphonamide drugs was demonstrated. For example, malonate was known to be sufficiently like succinate to be able to form a complex with succinic dehydrogenase, but to be unlike it enough not to go through the stages of dehydrogenation and dissociation. If enough malonate was present, most of the enzyme became involved in formation of the more stable complex; the enzyme was, in fact, inhibited by malonate which was competing with succinate for the attention of the enzyme. This inhibition could be reversed by increasing the concentration of succinate, renewed by adding more malonate, and so on. In just such a way the sulphonamides are held to compete with *p*-aminobenzoic acid, and to prevent its further utilization. Although a certain amount is known about the functions of *p*-aminobenzoic acid, little is known about the receptors with which the competition is concerned Possibly the sulphonamides form complexes with an enzyme or series of enzymes, analogous to the malonate–succinic dehydrogenase complex. Possibly they form complexes with a compound normally associated with *p*-aminobenzoic acid and thus interfere with its function; it has been suggested that reductone may be such a compound, and reductone-*p*-aminobenzoic acid and reductone-sulphonamide complexes have been demonstrated.

Whatever the exact point of attack of the sulphonamides, it was clear that they acted by competing with *p*-aminobenzoic acid, shown to be a growth-factor for a wide variety of organisms, and considered to be an essential metabolite at least for those which are sulphonamide-sensitive. Realization of this, together with the marked chemotherapeutic success of the sulphonamides, stimulated the development of the Fildes–Woods 'rational approach' to chemotherapy. Briefly, it was suggested that analogues of known bacterial growth-factors (or essential metabolites) might be found to bear the same relationship to the parent growth-factor as the sulphonamides bear to *p*-aminobenzoic acid and thus prevent their utilization (or synthesis). Such analogues should prevent or slow bacterial growth and might thus prove to be of use as chemotherapeutic agents.

Several hundred analogues of compounds known to be of importance to the cell have been synthesized and many of them possess the predicted bacteriostatic property *in vitro*. Of the active compounds many are inactive *in vivo*, and others are too toxic to the host to be considered as chemotherapeutic agents. Only certain analogues of pantothenic acid (for example, phenylpantothenone) retain their property of inhibiting growth of the micro-organism *in vivo* and at the same time fulfil the other requirements of a chemotherapeutic drug; had it not been for the development of other antimalarial drugs, phenylpantothenone might to-day be regarded as a practical achievement for the rational approach. Superficially, however, this approach has yielded nothing of chemotherapeutic value; but certain points must be considered before passing judgment. The first concerns the choice of factor. Such is the fundamental similarity of metabolic patterns in all cells that an agent which interferes with a given process in one cell is likely to interfere in a similar way with the metabolism of another cell, independent of species. The repetition of metabolic patterns is seen most clearly in the case of the B group of vitamins. Members of this group have an extremely wide distribution as essential metabolites, and analogues of them have been synthesized and tested in the greatest number. It is not difficult, therefore, to understand the failure of these analogues in chemotherapy, for they interfere with the same fundamental processes in both parasite and host; indeed, several analogues, such as those of aneurin, nicotinic acid and folic acid, have produced in mammals syndromes indistinguishable from those produced by simple dietary deficiencies of the factors concerned.

The relationship between an inhibitory compound and the growth-factor on which it is modelled tends rather to be taken for granted. An analysis of any existing relationship and of the metabolic effects produced by the antagonism is desirable not only for a proper understanding of the mode of action of the analogue (and thereby of the corresponding growth-factor) but also so that the development of more efficient inhibitors should proceed logically. Evidence for the existence of a relationship is of three main types. First, the actual existence of a mutual antagonism has to be demonstrated between growth-factor and analogue. This aspect has been very widely studied and has been the subject of several reviews. Second, even though such an antagonism is established, it should not be assumed that growth inhibition is solely due to it. Specificity of action should be examined in as wide a variety of organisms as possible, and reversal of the inhibition should be limited to the growth-factor in question and to any compounds which may replace it in the growth of organisms requiring it. Finally, the effects produced by the analogue should be just those which are seen as the result of a nutritional deficiency of the growth-factor.

It is desirable also that the exact point of attack of the inhibitor should be investigated. This presents a complex problem, for the various possible processes which can be interfered with are all closely interrelated, and it is not easy to separate primary and secondary effects. Of the three main points at which an analogue can cause a block, the first two, assimilation of the growth-factor and its elaboration into a functioning form, are particularly difficult to separate. No instance of an analogue preventing the assimilation of a growth-factor is known, though little work has been done on this aspect. Most work has been concentrated on the metabolism of the factor once it has entered the cell, and this includes studies on the further elaboration of the growth-factor molecule. As instances, the conversion of *p*-aminobenzoic acid to folic acid and its inhibition by sulphonamides, and the conversion of glutamic acid to glutamine and its inhibition by the sulphoxide of methionine might be cited as examples. In the second example it is also known that the methionine sulphoxide does not interfere with the assimilation of glutamic acid from the external environment but only with its conversion after entry into the cell. The third point at which analogues may exert their effect is during the actual functioning of the growth-factor, that is, at the point of catalysis. Here again there is very little information available, although the hydrazide of glutamine has been shown to inhibit the breakdown of glutamine to glutamic acid and ammonia, and to be correlated with the inhibition of the growth of streptococci caused by the hydrazide.

To obtain by the rational approach analogues which possess the selective toxicity so necessary for successful chemotherapy, processes must be blocked which are quantitatively more important, or peculiar, to the parasite. It seems unlikely that the sulphonamides are the only analogues of an essential metabolite which fulfil this requirement; with increase in our knowledge of the metabolism of micro-organisms and of the parasite-host relationship, it is probable that more agents will become available. The sulphonamides owe their chemotherapeutic success to the inhibition of a reaction which seems to be absent from animals but essential to micro-organisms (and to members of a number of other species). In several bacteria the sole defect produced by the sulphonamides seems to be an inhibition of the incorporation of *p*-aminobenzoic acid into the folic acid molecule. Animals cannot carry out this synthesis and rely upon a supply of pre-formed folic acid being present in the diet; in other words, the biochemical lesion induced in sensitive organisms by the sulphonamides already exists in the host. Nevertheless, the host may be partially dependent on factors synthesized by its intestinal flora; the effect of sulphonamides on such syntheses may account in part for the toxicity sometimes seen in sulphonamide therapy. Moreover, it is known that much of the folic acid present in animal tissues and fluids is in the form of conjugates, a form not available to the parasite. The position, then, is that formation of folic acid by the host-dwelling parasite is blocked from below by the sulphonamides and from above by natural lack of the enzymes necessary for releasing folic acid from its conjugates; the host, on the other hand, relies on a supply of pre-formed folic acid and converts it largely to a form not available to the parasite.

A similar situation may explain the partial success of analogues of pantothenic acid, for this factor is known to exist in animals in the form of co-enzyme A, a more complex molecule. Although micro-organisms carry out a similar elaboration of pantothenic acid, they do not seem to be able—through inability to absorb it or through slight differences in structure—to make use of animal co-enzyme A to supply their own requirements.

The sulphonamides, and possibly also analogues of pantothenic acid, thus provide examples of compounds which interfere with reactions peculiar to the parasite and exploit qualitative differences in metabolism. Further inhibitors of this type, as already stated, will develop logically from the finding of further synthetic reactions of the parasite. A hopeful field, already opening out, is associated with peptide metabolism. Species specificity of structure is nowhere so marked as in the proteins, and it is in their synthesis that species-specific biochemical reactions are most likely to be found. For example, a certain amino-acid sequence in a simple peptide might be harmless or even favourable to one species, but toxic, through slight differences in sequence from normal peptides of that species, to another. It is interesting to note in this connexion that several of the naturally occurring antibiotics are peptides. One of them, lycomarasmin, is the tripeptide seryl-glycyl-aspartic acid. Its toxicity towards *Lactobacillus casei* and the tomato plant (it is the active agent of the tomato-wilt fungus *Fusarium lycopersici*) is annulled competitively by strepogenin, also a peptide and a growth-factor for a number of organisms. The observed biological relationship suggested a possible chemical relationship (using the rational approach 'in reverse'), and the synthesis of seryl-glycyl-glutamic acid yielded a compound with some strepogenin activity, both as growth-factor and as antagonist to lycomarasmin. On this and other grounds, it is not impossible that other natural antibiotics may turn out to be analogues of essential metabolites; there is already some evidence for this in the case of streptomycin.

For successful chemotherapy, though, it may not be necessary to restrict attention to reactions which are peculiar to the parasite. The temporary blocking of processes quantitatively more important to the parasite than to the host might prevent growth of the former for long enough to allow the natural defences of the host to overcome the invader without seriously damaging the host.

Another point to be considered is that, although the rational approach has yielded little in the way of chemotherapeutic agents, it has provided metabolic tools of the greatest value in investigating the actual function of the growth-factors. As they inhibit specifically the synthesis or utilization of the growth-factor, they provide a chance of tracing the primary effect of that factor. For example, γ-3,4-urylenecyclohexylbutyric acid, an analogue of biotin, inhibits the growth of *Lactobacillus arabinosus*, and this inhibition is reversed competitively by biotin. The amount of biotin required to overcome the inhibition by a given concentration of the analogue is decreased ten-fold if oxaloacetic acid is present. This indicates that one function of biotin is in the synthesis of oxaloacetic acid.

Similarly, use of the sulphonamides has contributed greatly to knowledge of the function of *p*-aminobenzoic acid, which is involved in the synthesis of folic acid, purines, thymine, methionine, lysine, serine and possibly valine. Inhibition of the synthesis of folic acid by sulphonamides has been demonstrated in a direct way. Further use of the analogues in such researches may well reveal points suitable for chemotherapeutic interference.

When a suitable growth-factor or essential metabolite has been selected for modification, it has yet to be decided what changes are to be wrought in the original molecule to produce an efficient inhibitor. So far it has only been possible to predict in a very general way whether a given analogue is likely to prove inhibitory. Trial and error may be costly of time and fail completely to give an active compound, for it is not enough to go on simple pictorial analogy. It is not enough because an analogue may look like a metabolite and yet lack the chemical groupings necessary for combination with, for example, an enzyme; and because it leads to over-emphasis of the geometry and under-emphasis of the chemistry of the molecule. At the same time, pictorial analogy is too much, for it leads to possible overloading of the analogue with unnecessary groups which have nothing to do with the attachment of it or the metabolite to the enzyme. In order to model inhibitors more successfully on essential metabolites two things at least must be known: first, the structure of the metabolite to be imitated; and secondly, the precise way in which it associates with the bacterial enzyme to which it is related as substrate, co-enzyme or product.

Many attempts have been made to explain the action of the antimalarial drugs on the basis of their being metabolite analogues, and there is much evidence, both chemical and biological, that quinine, 'Mepacrine' and 'Pamaquin' and possibly also the more recent anilinopyrimidines act as inhibitors of reactions involving riboflavin, at any rate in bacteria. As pointed out above, the fact that a substance chemically related to a growth-factor can compete with that growth-factor does not of necessity imply that an associated growth inhibition can be correlated with the metabolite analogy. Thus the final biological proof that these antimalarials are active solely because tinthey erfere with the action of flavin derivatives has yet to be provided. The newer and highly successful 'Paludrine' was developed by logical chemical steps from 'Mepacrine'; yet in no system has it been shown as a riboflavin competitor. There is no biological evidence for the mode of action of 'Paludrine', but it has been suggested that either by chelating a metal or by nature of the intrinsic size and shape of its cation (there is evidence that it exists as a pseudo-triazole involving a hydrogen-bond) it may possess a structure similar enough to that of the porphyrins to interfere with their metabolism. It is also possible that, as also in the case of the natural antibiotics, discovery of the mode of action of 'Paludrine' may disclose a new essential metabolite.

Had oxine (8-hydroxyquinoline) not already been well known as a chelating agent, the strong antibacterial activity of it and its derivatives might have been difficult to explain, particularly as the lethal action against Gram-positive organisms is far more powerful at low concentrations ($10^{-5}M$) than at higher ones ($3 \times 10^{-3}M$). The hypothesis advanced to explain their action against Gram-positive organisms, and backed by much experimental evidence, is this: at low concentrations the oxine chelates cobalt (cobalt is the only metal which will reverse the inhibition) and thus exposes the bacteria to the action of a second metal which catalyses the oxidation of a chemical group protected by the cobalt. Stronger solutions of oxine protect the organism by removing the injurious metal as well. The second metal has been identified as ferrous iron, and it seems that in the presence of lethal concentrations of oxine the organisms actually die of iron poisoning. Although oxine and its derivatives are not growth-factor analogues, their action is to prevent the normal functioning of essential ions, and a consideration of them is germane to any discussion on chemotherapy. Their mode of action, a disturbance of an existing balance with lethal results to the micro-organism, is worth considering in connexion with other antibacterial agents.

So the biochemist and the chemist, by producing changes in the structure of compounds already known to show a selective toxicity towards the parasite, may produce more and more efficient chemotherapeutic agents. But inevitably, as more is learned of the comparative biochemistry and physiology of micro-organism and potential host, and of those synthetic processes which are more peculiar to the micro-organism, the biologist will seek the closer co-operation of the chemist so that together they may plan, synthesize and test new chemotherapeutic agents.

PARTITION CHROMATOGRAPHY ON PAPER, ITS SCOPE AND APPLICATION

By Dr. R. CONSDEN

Wool Industries Research Association, Leeds

WITHIN the last twenty years, chromatography has become increasingly important as an analytical tool. The purpose of this article is to review the uses of partition chromatography on paper, which, since its inception four years ago[1], has had a wide application and which promises to become as well established as the older forms of chromatography. It should be emphasized, however, that, as mixtures, especially from biological sources, may be very complex, preliminary separations[2-5] may often be necessary before paper chromatography can be used to the best possible advantage. For recent developments in all types of chromatography, the reader is referred to a number of articles indicated in footnotes 6–9.

Partition chromatography was first developed by Martin and Synge[10] at the laboratories of the Wool Industries Research Association. In this type of chromatogram, separations are achieved because of the differences in partition coefficients between aqueous and non-aqueous phases of the components of a mixture. Using silica gel as the supporting medium for the aqueous phase and eluting with certain water-saturated immiscible organic liquids, separation and estimation of a number of acetyl-amino-acids were effected. This provides a relatively simple and valuable method for the quantitative analysis of some half-a-dozen amino-acids in protein hydrolysates, after acetylation. With the free amino-acids themselves, it was found that owing to their strong adsorption by the silica gel, separations could not be achieved. However, cellulose, in the form of filter paper, was found to be suitable as the stationary support. In this method, a filter paper strip, carrying a mixture of amino-acids (a few micrograms of each) near its upper end, is hung from a trough containing water-saturated solvent (for example, *n*-butanol, phenol, *s*-collidine), the whole system being in an atmosphere saturated with respect to solvent and water vapours. The solvent syphons down the strip, and after a suitable time the amino-acids are revealed by drying the paper and spraying with a solution of ninhydrin and then gently heating. (A simplification of this method—'ascending' chromatography—has been recently reported[11].) It was found that the movement of amino-acids corresponded fairly closely with that calculated from their partition coefficients, thus demonstrating that the cellulose, as in the case of silica gel, acts as an inert support for the aqueous phase. This type of chromatogram is of value because of its simplicity and because many analyses may be carried out on one paper strip, using only very small amounts of material. An early application[12] was to show that *nor*-leucine was not present in spinal cord, as had been originally supposed.

No single solvent has been found which will separate all the common amino-acids on a paper strip; but a more complete separation can be obtained in the 'two-dimensional' technique in which the mixture applied near one corner of a filter paper sheet is chromatographed in one direction with one solvent and then in a direction at right angles with another solvent. The components are thus distributed over the area of a sheet, and by choosing two solvents with different properties, such as *s*-collidine for one direction and phenol for the other, most of the common amino-acids are separated, only $\frac{1}{3}$–$\frac{1}{2}$ mgm. of protein being required, and all may be separated by additional one-dimensional chromatograms in other solvent systems. On a two-dimensional sheet, the amino-acids occupy characteristic positions, depending on the solvents used, and 'maps'[1,14–17] have been published showing the positions of ninhydrin colouring constituents of biological mixtures.

Ninhydrin has been found to be the best general indicator for the amino-acids as it is very sensitive and little affected by traces of solvents left on the paper after drying. However, as is well known, it is not specific for the amino-acids; any substance having both free amino- and free carboxyl-groups, such as peptides and non-α-amino-acids, gives colours, while less intense colours are given by nitrogen bases, including amino-acid esters. Though not so sensitive as ninhydrin, β-naphthaquinone sulphonic acid (Folin's reagent) is a useful general indicator, and amino-acids and peptides can be located by their weak fluorescence in ultra-violet light[18]. A number of more specific indicators are available, though, in some cases, thorough removal of solvent from the paper may be necessary, prior to their use. Diazotized sulphanilic acid is an even more sensitive reagent for histidine than ninhydrin. For tryptophan, *p*-dimethylaminobenzaldehyde in acid solution is useful, and with reduced tryptophan, 2:4-dinitrophenylpyridinium chloride gives a strong cerise colour. Other useful reagents are potassium iodoplatinate for amino-acids which carry the thio-ether link (for example, methionine and lanthionine), and periodic acid in conjunction with Nessler's solution for the aliphatic hydroxy-amino-acids. The ingenious use of *D*-amino-acid oxidase by Synge (unpublished) for revealing configuration has been applied by Jones[19] to show that the leucine residues of aerosporin have the *D*-form. Dent (private communication) has developed a method for distinguishing between α- and non-α-amino-acids, by removal of the former as their copper complexes; and the latter, which do not readily form copper complexes, are revealed by ninhydrin.

An early application of the two-dimensional paper chromatogram was by Edman[13], who demonstrated the amino-acids in hypertensin hydrolysates. Modifications of amino-acid residues in a protein after chemical treatment can often be easily observed. Thus, small amounts of lanthionine and cysteic acid have been demonstrated to be present in hydrolysates of wool tips[14], showing that the action of weather and light have modified some of the combined cystine. Cysteic acid has been shown to be present in hydrolysates of wool which had received various oxidizing treatments[3,14], and some destruction of proline and tyrosine has been observed after chlorination of wool. A not unimportant use of paper chromatography is as a control for synthesis[20] and separations[3,21], and to test the purity of substances. Mention should be made of its growing use as a control for various industrial processes involving utilization of amino-acid and peptide mixtures, such as in penicillin and streptomycin production; but, so far, little has been published in this connexion.

New or unsuspected constituents can be revealed and it is often possible, from its position on the chromatogram, to make a reasonable guess as to the nature of a new substance. For example, Consden, Gordon and Martin (unpublished) observed what was considered to be a weakly basic substance in elastin hydrolysates, and this was confirmed by subsequent electrodialytic experiments. Jones[22] demonstrated the presence of α-γ-diaminobutyric acid in aerosporin, and Borsook *et al.*[23] showed that lysine was metabolized by guinea pig liver to α-aminoadipic acid. Amino-acids, other than the α-variety, and amino-acids not common in animal proteins appear to be widely distributed in plant and bacterial extracts such as α- and γ-amino-butyric acids[15,16]. Indeed, plant extracts offer a vast field for paper chromatography, and already the first reported applications[15,24] have yielded much valuable information, both as regards new constituents and metabolism. The non-protein nitrogen fraction of plants may sometimes contain only relatively few ninhydrin colouring constituents. For example, Consden and Gordon (unpublished) found that an aqueous extract of tea contains only three such substances in strength, namely, aspartic and glutamic acids, and the third, now under investigation, is believed to be a mono ester of glutamic acid. There are obvious applications of paper chromatography in the study of plant extracts to agriculture and animal nutrition.

In the medical field the usefulness of paper chromatography has been shown by Dent[25] in studies of pathological urines and in determining the fate of proteins after digestion[26]; and there is a great potential use for radioactive isotopes, as is evident from metabolic studies with radioiodine[27], radiocarbon[23], and radiosulphur[28].

There is a fast-growing list of substances other than amino-acids to which paper chromatography is applicable, and which can only be referred to briefly here. An important field was opened up by Partridge[29,30], with the sugars, and the introduction of specific indicators[31] should prove to be particularly useful. Another potentially important field, especially for the study of prosthetic groups, are the flavines[32] and purines[33]. Other substances reported to be separable on paper chromatograms are anthocyanine pigments from petals[34], organic acids[35], adrenalin and related substances[36], creatine and creatinine[37], penicillins[38] and vegetable tannins[39].

Extension to quantitative analysis has enhanced the usefulness of paper chromatography. For many purposes, a rough estimate of a given amino-acid may be usefully made by comparison of the intensity of its ninhydrin spot with that of known amounts of the same amino-acid chromatographed under the same conditions[3,40]. This is clearly capable of industrial application. A refinement of this visual comparison method for both sugars and amino-acids has been reported[41]. The ninhydrin colours themselves have been used for estimations after extraction from the paper[40]. Extraction of amino-acids as their copper complexes, followed by polarographic determination of the copper, has been described[42,43]. This method was used to estimate the five amino-acids produced after hydrolysis of gramicidin S[42]. Alternatively, the copper can be estimated colorimetrically[44], and this method was used by Jones to show that the proportion of leucine to threonine in hydrolysates of aerosporin is 1 : 3 [22]. An interesting isotope dilution method has been described[44a] in which amino-acids are first converted to *p*-iodobenzenesulphonyl derivatives containing radio-active iodine or sulphur and then estimated on paper chromatograms by counting. Quantitative analysis on paper chromatograms of substances other than amino-acids have been devised, notably for sugars and their derivatives[45,46].

Perhaps the most important application of paper chromatography is to elucidate the sequence of amino-acid residues in proteins and polypeptides. This is a problem of fundamental importance, but has long been unsolved because of the lack of methods for handling complicated mixtures of peptides which result from partial hydrolysis; and, in fact, very few peptides have been isolated and identified[47] by the traditional chemical methods. However, simple peptides behave on paper chromatograms as satisfactorily as amino-acids, and techniques have been devised[4] to separate and identify lower peptides in complex mixtures. The sequence of the amino-acid residues of gramicidin-S was thus established[48] as -(α-valyl) - ornithyl - leucyl - phenylalanyl - prolyl-. Tyrocidin appears to incorporate the sequence -valyl-ornithyl-leucyl- and probably the sequence -aspartyl-glutamyl-tyrosyl- in its structure (Consden, Gordon and Martin, unpublished). There would appear to be a promising field for similar investigations of other polypeptides, the list of which is rapidly growing, consisting of residues of a few varieties of amino-acid or having molecular weights intermediate between simple molecules and proteins.

With the proteins themselves, the mixture arising from partial hydrolysis is likely to be vastly more complex, and it is too much to expect that the structure of a protein could be pieced together from the peptides identified. So far as I am aware, wool is the only protein which has been examined in this way, and preliminary reports have been given by Martin[49] of the identification of nineteen dipeptides of aspartic and glutamic acids[50] and of a number of peptides from the less completely investigated neutral and basic fractions of partial hydrolysates of wool[51]. One conclusion from these studies is that a substantial proportion of the glutamic acid is linked with itself in the wool polypeptide chain. Recently, Consden and Gordon[5] have described techniques for identifying peptides of cystine, and it can be concluded that, in wool, cystine is linked *via* one of its amino-groups and *via* one of its carboxyl-groups to residues of glutamic acid and to residues of most of the neutral amino-acids and that a substantial proportion of proline residues, if not next to, are not far from, cystine residues. The possibility of identifying a large number of peptides in partial hydrolysis mixtures should be a big step forward in our knowledge of protein structure.

It has not been possible to deal adequately here with all aspects of paper chromatography, especially pending publication of the many important developments which are now rapidly taking place. However, enough has been indicated to justify the confident expectation that, before long, this technique will be in common use in many laboratories.

Grateful acknowledgment is made for useful information from Drs. C. E. Dent and A. H. Gordon and to the Director of Research, Wool Industries Research Association, for his interest and advice.

OBITUARIES

Mr. S. G. Brown, F.R.S.

SYDNEY GEORGE BROWN died on August 6 at Sidmouth, where he went to live on his retirement. He was seventy-five years of age.

Born in Chicago in 1873, his father having gone there to live, he was brought to Great Britain at an early age. He was educated at Harrogate College and University College, London. On leaving college he served as an apprentice in the works of the late Col. Crompton at Chelmsford, where he was principally engaged on calculations and design of dynamos and motors. In 1908 he married Alice Stower, niece of Prof. John Perry, whose close friendship he enjoyed until the time of the latter's death.

It is by his numerous inventions that Mr. Brown became famous. He claimed to have taken out about a thousand patents, commencing when sixteen with a home-made phonograph. In 1899, when only twenty-six years of age, he produced the drum cable relay used in submarine telegraphy. This was followed by the magnetic shunt and other devices connected with duplex working over long-distance cables. Also at this time, with Sir Henry Hozier, he demonstrated a system of directional beam wireless using a parabolic reflector of wire. Signals were transmitted for over a mile between a coastguard station and a lighthouse at Beachy Head. These distances were later increased. This patent was dated 1899.

Finding difficulties in getting his inventions manufactured, he opened in 1910 his own workshops near Liverpool Street, London. After two moves to obtain more space he decided in 1915 to have his own factory built, for which purpose he purchased a large site in Acton, London.

In 1910 he patented his reed type telephone earpiece, by means of which wireless messages could be read when otherwise inaudible. They were adopted as standard by the Royal Navy. He worked on electrical aids for the deaf and was possibly the first to demonstrate bone conduction for hearing. In 1909 he perfected various types of relays for the purpose of amplifying feeble currents both for use in wireless and telephony. This was in the days before the introduction of the thermionic valve. Early in 1914 one of these, the microphone relay, was accepted by the Royal Air Force for use in aeroplanes. By its use wireless messages could be received during flight. The same relays were used by the Admiralty for extending the range of signalling at sea.

Mr. Brown conducted considerable research on rare metals for contact purposes. At the request of the Admiralty he designed the electro megaphone for loudspeaking on warships. One form of this instrument is used on the London Underground Railways for speech between guard and driver. The late Admiral Lord Fisher personally wrote thanking Mr. Brown for his work on relays for detonating mines, using the current from a selenium cell operated by the rays of a searchlight.

The greatest of Mr. Brown's inventions, however, and the one that he himself ranked as his highest achievement, was his gyroscopic compass. The two principal features are the vertical axis and the liquid ballistic. By the first, friction is reduced to a minimum by raising and lowering the whole of the north-seeking parts, including the gyro wheel, at more than a hundred times a minute, using a column of oil, pump-operated. To overcome quadrantal error, common to all gyro compasses, he replaced the solid weight used to precess the compass by a liquid which was free to flow from side to side of the wheel during the rolling of the ship. To work in conjunction with his compass he designed an automatic helmsman which makes it possible to steer a course at sea direct from the compass. He further made a multiple repeater for the ease of steering by hand, also a recorder on which the course of the ship can be plotted on a moving chart. His last invention was a gunnery control compass. This demanded an extreme accuracy at sea only previously associated with a laboratory compass working in a stationary position on land. Such a compass was completed and had passed Admiralty requirements when its adoption was delayed owing to the Second World War making its application impracticable.

With the introduction of broadcasting, Mr. Brown turned his mind to mass production, thousands of pairs of headphones being produced daily. He gave the name to the loudspeaker. While he produced many types fitted with horns he foresaw the development of the large cone diaphragm back in 1910, when he referred to its possibilities in his receiver specification.

During the First World War, Mr. Brown served on the Research Committee for the Detection of Enemy Submarines, the Inventions Board and the Admiralty Ordnance Council. He was elected a fellow of the Royal Society in 1916. In March, 1909, he read a paper before the Royal Institution on "Submarine Telegraphy", and in 1920 one on the "Gyroscopic Compass".

Apart from his activities with the Company that bears his name, he founded and was chairman of the Telegraph Condenser Company.

With all his inventions Mr. Brown acted as his own designer. He was an accomplished engineer capable of giving advice in any department of his works. He was held in great respect by his staff, with whose assistance he earned a great reputation for the high quality of all his work. H. PASMORE

Prof. Marcel Brillouin

THE Nestor of French physics, Marcel Brillouin, formerly professor of physics in the Collège de France, died on June 16 at the age of ninety-four. He belonged to a generation of men of science who could not only master the whole realm of their subject but also make important original contributions to almost every branch of it. As a result they were able to present that subject to their students in a most perfect form, thus providing them with a solid foundation for their own future activities in this field. Prof. Brillouin's lecture courses at the Collège de France provide an outstanding example of this almost extinct art, and many of them have been published in book form, like the well-known "Leçons sur la viscosité des liquides et des gaz".

Like many great physicists, he started as a mathematician at the École normale; but his natural inclination soon diverted him first to mechanics and later to physics as a whole. Thus he acquired skill in the use of mathematics as well as in the handling of apparatus which enabled him to carry out investigations requiring refined experimental and mathematical techniques at the same time, which is so rarely found in physicists of the present generation.

Only a brief indication of Brillouin's most important research subjects can be given here. In hydrodynamics he did fundamental work on the theory of discontinuity surfaces in liquid flow and the formation of vortices on similar lines to Helmholtz, and in aerodynamics he developed a theory of the dispersion of sound. In thermodynamics he devoted himself to the study of permanent deformations of solids and to the specific heat of black body radiation, and he derived the proportionality of this quantity with the third power of absolute temperature. The kinetic theory of matter was enriched by Brillouin's contributions to the theory of diffusion and viscosity in gases and liquids, and he also took part in the once topical controversy on the apparent contradiction in statistical mechanics between the reversibility of the laws of dynamics and the irreversibility of those of thermodynamics. He was very much interested in geophysics as well, and he contributed to this branch of applied physics by papers on the circulation of the atmosphere, the formation of rain, the theory of the tides, etc. An outstanding piece of research in this field consisted in a series of precision measurements of gravity within the Simplon tunnel aiming at a determination of the shape of the 'geoid'. Although naturally his main activity was in the domain of 'classical' physics, he was nevertheless actively interested in the theory of relativity and in quantum theory, where he made an early attempt to give a representation of quantum phenomena in terms of a continuum theory.

It was a source of great satisfaction to Brillouin that the successor to his chair was one of his own sons, Léon Brillouin, who, carrying further the work of his father, has become one of our leading theoretical physicists. R. FÜRTH

Prof. Beatrice Edgell

THE death of Prof. Beatrice Edgell, professor emeritus in the University of London, takes from us one of the significant figures in the development of British psychology. Born in 1871, she was of the same generation as McDougall and C. S. Myers, with whom she collaborated in the pioneer work of the British Psychological Society and with whom she helped to establish the traditions on which the study of psychology is still based in British universities. Trained first in philosophy at the University College of Wales, Aberystwyth, she turned to experimental psychology and studied at Würzburg, where the use of experimental method was being developed in the study of the processes of thought and judgment. Throughout her life she combined her interests in philosophy and in experimental psychology, though with a special leaning to the latter, and from 1897 until 1933 she was head of the Department of Philosophy and Psychology at Bedford College in the University of London.

At a time when in many universities psychology was at best a subordinate partner of philosophy, her position as professor of psychology in charge of both subjects was unusual. The laboratory she established bears witness to her concern for exact and objective experimental method aided by the best material equipment then available. Her chief publications ("Theories of Memory" (1924), "Mental Life" (1926) and "Ethical Problems" (1929)) indicate the two sides of her interest, as does the fact of her contributing both to psychological journals and to the *Proceedings of the Aristotelian Society*. Her example and influence thus aided the development of psychology in Britain as an independent experimental science which still retained the stabilizing effect of philosophical discipline. Her psychological interests centred largely on the cognitive aspect of mental experience, especially memory and perception, and she also paid particular attention to the experimental approach to æsthetics. As a teacher, however, she was stimulating over a wider range. "Ethical Problems" was written specially with the view of helping nurses, and her text-book, "Mental Life", was intended for students preparing for social work. Precise of mind and emphatic of utterance she was an excellent teacher, and she is held in affectionate respect by a large number of former students, many of whom are now engaged in psychological work applied to industry, education and various branches of social work.

In her retirement Prof. Edgell still occupied herself with psychology, including its newer developments. She was recently, for example, using the Rorschach test with critical appreciation. She continued to help students, and to take an active interest in the British Psychological Society, of which she was a past president and honorary fellow. During the War she wrote a history of the Society, part of which she read at the annual meeting of the Society in 1946. This was the first occasion on which many of her younger colleagues had met her, and they will remember her as they saw her then, frail, alert and indomitable.

NEWS and VIEWS

Psychological Medicine in Glasgow: Prof. T. Ferguson Rodger

DR. T. FERGUSON RODGER has been chosen as the first occupant of the newly founded chair of psychological medicine in the University of Glasgow. Dr. Rodger graduated in science and medicine at Glasgow in 1927–29 and holds the diploma in psychological medicine of the University of London. During 1931–32 he worked at Johns Hopkins University, where he was a pupil of Adolf Meyer. From 1933 until 1939 he was senior assistant at Glasgow Royal Mental Hospital (Gartnavel), and an assistant to the lecturer in psychiatry in the University. Throughout the War he served in the Royal Army Medical Corps as consulting psychiatrist at Headquarters, Land Forces, South-East Asia, and at General Headquarters, India. Latterly, he has been a commissioner of the General Board of Control (which functions under the Lunacy, Mental Treatment and Mental Deficiency Acts). Dr. Rodger has specialized in psychosomatic medicine. He was responsible for research into the methods of selecting officers for the army. He has also published work on fibrositis and on night-blindness.

Pathology in Glasgow: Prof. G. L. Montgomery

GEORGE LIGHTBODY MONTGOMERY has been appointed to the St. Mungo-Notman chair of pathology (associated with the Royal Infirmary, Glasgow) in succession to Prof. John W. S. Blacklock, who has moved to St. Bartholomew's Hospital, London. Prof. Montgomery graduated at Glasgow (M.B., Ch.B., 1928; M.D., 1946), and also holds the Ph.D. degree of the University of St. Andrews (1936). After holding appointments at Glasgow Royal Infirmary, in 1931 he became lecturer in clinical pathology at St. Andrews and assistant pathologist at Dundee Royal Infirmary. Since 1937 he has been Gardiner research lecturer in the pathology of disease in infancy and childhood in the University of Glasgow, and pathologist at the Royal Hospital for Sick Children, Yorkhill. During almost the whole of the

War he served on the Directorate of Pathology at home, in the Central Mediterranean and in South-East Asia. His researches include work on the renal function in various morbid states, on diseases of childhood (with special reference to non-tubercular infections of the lung), and on the healing of lung injuries. He has recently taken part in the trials of streptomycin carried out by the Medical Research Council.

Victor Meyer (1848–97)

Among the many eminent German chemists of the latter half of last century, none enjoyed a higher reputation than Victor Meyer, who entered the University of Heidelberg in 1865 at the age of seventeen and, twenty-four years later, was chosen to succeed his old master Bunsen in the chair of chemistry there. Meyer was born at Berlin on September 8, 1848, being the son of a Jewish calico manufacturer. His home influences had tended towards the literary and artistic rather than the scientific, and Meyer, it is said, wished to become an actor, for which he had all the natural gifts. At Heidelberg, however, he came under the spell of Kopp, Kirchhoff, Helmholtz and Bunsen, and after a time became assistant to the last. From Heidelberg he went to Berlin to work under Baeyer, and successively held posts at Stuttgart, Zurich and Göttingen, before returning to his *alma mater*. With a fine voice, handsome presence and impressive manner, he became known as one of the best lecturers in Germany. With his other gifts he combined a passion for work, and was responsible for some three hundred memoirs. His most important investigations are referred to in the Memorial Lecture on Meyer delivered to the Chemical Society on February 8, 1900, by Sir Edward Thorpe, who had known him for thirty years. Unfortunately, his great mental activity brought on insomnia and he had several spells of ill-health. His death took place on August 8, 1897, when he was but forty-eight years of age. He had received many honours from scientific societies, and among these was a Royal Medal from the Royal Society awarded him two years after he had succeeded Bunsen.

Dedication of Private Woodlands

In the Forestry Commission Booklet No. 2 (H.M. Stationery Office, London, 1948) the purpose of the scheme for the dedication of private woodlands is explained. This purpose is to encourage the application of systematic management to private woodlands, become necessary, it is said, in the interests of national security because the reserves of standing timber have been greatly depleted during and since the War; and it might be added are still suffering from more or less crude over-felling, especially in the hardwood areas. Under the scheme the owner undertakes to use the land in such a way that timber production is the main object; to work to a plan to be approved by the Forestry Commission; to employ skilled supervision, and to keep adequate accounts. The object of the scheme is to ensure that replanting or regeneration of woodlands cut during the War shall proceed with continuity and rapidity, that this work in its young stages must be looked after until the young woods are established and, it is to be proposed, after that stage has been reached. Owners must make up their minds as to whether they are prepared to work the scheme; if they agree, they will receive State financial assistance. If the owner is unwilling to join the scheme or keep his woodland areas in proper order, the State will acquire them. Finally, some system of control of the sylviculture of private woodlands is deemed necessary.

To give effect to the scheme a deed of covenant in England and Wales and an agreement in Scotland will be entered into by which both the State and the owner undertake respective obligations as already mentioned. The Forestry Commission, as the agent of Government, will undertake to provide financial assistance to the owner on one of these bases at the owner's option: (1) To repay to the owner 25 per cent of the approved net annual expenditure on a dedicated woodland by way of loans which are described in the pamphlet. (2) To make payment to the owner as follows: (*a*) a planting grant of £10 per annum for every acre planted or replanted, softwood or hardwood, after date of dedication; (*b*) loans in addition to (*a*) on terms to be settled according to individual circumstances, the terms being given in the pamphlet; (*c*) a maintenance grant for fifteen years of 3*s*. 4*d*. per acre per annum on every acre dedicated that is planted properly and maintained; (*d*) a maintenance grant for fifteen years of 3*s*. 4*d*. per acre per annum from the date of dedication, on all productive woodlands other than new plantations covered already by (*c*) and (*d*). These grants will be reviewed and revised as may be necessary after five years from 1946–47 on the basis of ascertained costs. Dedication will run with the land and will not be affected by change in ownership.

New German Hydrographic Journal

With the first issue of the *Deutsche Hydrographische Zeitschrift* (1, No. 1, January, 1948), to the forthcoming appearance of which reference was made in *Nature* of August 16, 1947, p. 219, the publication of post-war articles by German oceanographers and other marine scientists and technicians commences. The first paper, by K. Kalle, deals with the problem of marine production and reviews research material and methods of investigation. Kalle compares the probable amount of marine production with the yields known from continental soils of the temperate zones. W. Hansen in the second article gives a general mathematical treatment of the oscillations of inertia in open and land-locked seas. The old nautical problem of the dip of the horizon is attacked once more theoretically, by H. Chr. Freiesleben. He derives a formula which, in order to be strictly employed, demands measurements of the air-temperature at the horizon immediately above the sea-surface. Another short but interesting contribution, by F. Errulat, describes a series of measurements of the earth-magnetic field on the Dacia Bank (between Madeira and Morocco); he concludes that the Bank has a core of eruptive rocks. The field of nautical technique is represented by a description of a direction-holder named "Polkreisel", by P. Christoph. Moreover, there is an article on the German Hydrographic Institute, its origin, its tasks, and its organisation by the director, Dr. Böhnecke, and finally there are obituary notes on several notable German scientists who had worked on nautical science and on oceanography. In the next issue (No. 2/3) of the *Zeitschrift*, which was expected to be distributed in the beginning of August 1948, there is to be (with other papers) articles on the bottom geology of the southern and middle Baltic, on a fundamental geodetic problem in sea-surveying, on magnetic storms, and on resonance oscillations of bights and the mouth correction for seiches.

Trade Unions in Industry

As part of a general production drive, the Trades Union Congress is inviting trade unionists to extend their knowledge of management in industry. Through its publicity organ *Industrial News*, the Congress has announced that it is co-operating with the National Institute of Industrial Psychology, the British Institute of Management, the Government Committee on Industrial Productivity and the Administrative Staff College in seeking ways to make workshops more happy and efficient places. Experiments are to be carried out on the problems of the effects of boredom in industry, the means of minimizing labour turnover and the training of new employees. The Trades Union Congress is asking members of trade unions to co-operate with these organisations by seeking goodwill for their officers at places suitable for experiment.

Cultivation of Root Vegetables

Bulletin No. 120 of the Ministry of Agriculture and Fisheries (H.M. Stationery Office. 9*d.* net) deals with all phases of the commercial cultivation of carrots, beetroot, parsnips, turnips, swedes and other minor root crops. A new revision (August 1947) of the third edition has recently appeared, and brings the subject-matter up to date. The most modern additions deal with row-crop cultivation, irrigation, and the control of weeds.

Precession of an Unsymmetrical Top

It has been known since the time of Lagrange's "Mécanique Analytique" (1788) that a rigid body smoothly pivoted at one of its points O and symmetrical about an axis passing through O can have steady motions of precession in which the axis of symmetry rotates uniformly about the vertical while the solid itself rotates uniformly about the axis of symmetry; but it has been generally supposed that there is no corresponding result if the body is unsymmetrical. However, G. Grioli (*Annali di Mathematica*, **26**, 1; 1947, and *Rendiconti dell' Accademia Nazionale dei Lincei*, **4**, 420; 1948) has shown that under certain conditions we can have steady precession of an unsymmetrical body about a non-vertical axis. If G is the centre of mass, it is necessary that OG should be perpendicular to one of the two circular sections of the momental ellipsoid at G, and that the axis of precession should be inclined to the vertical at a definite angle which can be calculated from the same momental ellipsoid. If these conditions are satisfied, there is a doubly infinite set of motions in which OG is perpendicular to the axis of precession, and the solid rotates uniformly about OG in the same time as OG rotates uniformly about the non-vertical axis of precession.

Geotectonic Map of North-west Germany

Last year the first German publication on scientific geology since the War was issued by the Reichsamt der Bodenforschung, Hanover, namely, a general geotectonic map of north-west Germany, scale 1 : 100,000 (15 sheets, 200 marks). This map comprises all wells and geological as well as geophysical results from 1934 up to 1945. The new map is supplemented by formation data, stratigraphic symbols, profiles, surface contour lines, data of the depths, and geophysical data. Moreover, there is attached a general map, scale 1 : 1,000,000, of the structures and two hundred salt domes in this area. A volume of annotations of the map is projected.

Society for Visiting Scientists

The Society for Visiting Scientists (5 Old Burlington Street, London, W.1) has been able to extend its facilities and membership for scientific workers resident in the United Kingdom. The number of such members is no longer limited, and applications for membership from scientific workers interested in the Society's aims will be welcomed by the Executive Committee. Applicants should apply to the Assistant Secretary, mentioning one or more members of the Society who would be willing to be their sponsors. The subscription for members resident in the United Kingdom is three guineas per annum, with an entrance fee of one guinea. Visiting scientists from overseas are charged an entrance fee of five shillings only, and pay an annual subscription only if they reside in the United Kingdom for more than six months. The Society now has more than 1,300 members, about 1,170 of whom are overseas. In addition to the opportunity of meeting visiting scientists, and thus furthering international contact and friendship among men of science, the Society's premises offer useful club facilities.

National Foundation for Scientific Research, Brussels

The twentieth annual report of the National Foundation for Scientific Research, Brussels, for the year 1946–47, gives lists of members of the various commissions, and a note on the Inter-University Institute of Nuclear Physics. It also includes full details of the forty-five research grants made for the year 1947–48, amounting to 2,062,500 francs, and an analysis of the distribution of grants made since the establishment of the Foundation. Special grants for the period 1947–48 have been allotted to M. Biquet for sinking wells in water-bearing strata for the study of the freezing of dead ground at great depths (150,000 francs); to Prof. F. Mayence for excavation at Apamée (100,000 francs); to MM. Gratia, Florkin, Massart and Desreux for completing the existing installation of apparatus for electrophoresis by a high-quality optical apparatus of the Klett or Pearson type (100,000 francs); and to Prof. Piccard and Prof. Cosyns for submarine investigations at great depths. A list of publications during the year by those receiving grants during 1945–47, arranged under authors' names, is appended.

International Union of Crystallography

The first General Assembly and Congress of the recently formed International Union of Crystallography was held at Harvard University, Cambridge, Mass., during July 28–August 3 and was attended by some 350 crystallographers of ten nations. In recognition of his epoch-making contribution to the modern development of the subject, Prof. M. von Laue (Germany) was unanimously elected honorary president of the Union. Officers were elected as follows: *President*, Sir Lawrence Bragg (Great Britain); *Vice-Presidents*, A. Westgren (Sweden), R. W. G. Wyckoff (United States); *General Secretary*, R. C. Evans (Crystallographic Laboratory, Cavendish Laboratory, Cambridge); other members of the Executive Committee are M. J. Buerger (United States), P. P. Ewald (Great Britain), A. L. Patterson (United States), J. Wyart (France). Statutes and by-laws of the Union were adopted, and the adhesion of Great Britain, the United States, Canada and Norway was recognized. Commissions of the Union were established as follows: *Acta Crystallographica*, International Tables, Structure Reports, Crystallographic Apparatus, Nomenclature, Crystallographic Data. Crystallographers throughout the world interested in the work of any of these Commissions are invited to make contact with them through the General Secretary. The second General Assembly and Congress will be held in Europe during the summer of 1951.

Mechanization of African Agriculture

PROBLEMS likely to be encountered in the mechanization of African agriculture are to be studied by a mission which is visiting Uganda, Tanganyika, Nyasaland and Nigeria. The leader is Dr. J. R. Raeburn, of the Agricultural Economics Research Institute, Oxford, and he is accompanied by Mr. J. W. Y. Higgs, lecturer in agricultural economics, University of Reading, and Mr. R. K. Kerkham, Uganda Agricultural Service, who is at present stationed at the Uganda Agricultural Research Station. The terms of reference are: "To make a systematic survey of the sociological, economic, agricultural and technical problems which must be studied if mechanization of agriculture in the Colonies is to develop along sound lines, including *inter alia* the forms or organization required to achieve the best results (for example, whether mechanization should be on a co-operative, group or peasant basis), the most profitable lines of future research into problems arising out of mechanization, the economics of it and the types of tractors and implements which would be likely to be most suitable to the differing African communities, and such questions as the technical training of African craftsmen, the division and displacement of labour which will result from mechanization and its impact on current farming and social systems."

Colonial Service Appointments

THE following appointments in the Colonial Service have been announced: A. Bolton, plant breeder, Kenya; E. A. Rosenquist, botanist, Malaya; J. A. F. Gerrard, geophysicist, Uganda; A. D. Campbell, veterinary officer, Nigeria; D. W. D'Silva, assistant conservator of forests, British Honduras; H. T. Hayes, fisheries officer, Gold Coast; G. H. Lunam, fisheries officer, Nigeria; D. M. Rhodes, fisheries officer, Uganda; O. E. Symes, fisheries development officer, Nigeria; T. R. Hayes (principal agricultural officer, Uganda), assistant director of agriculture, Uganda; R. B. Jagoe (botanist, Federation of Malaya), senior botanist, Federation of Malaya; H. T. Pagden (entomologist, Federation of Malaya), senior entomologist, Federation of Malaya; D. H. Welsh (agricultural officer, Nigeria), principal of schools, Agricultural Department, Nigeria; D. B. Fanshawe (assistant conservator of forests, British Guiana), senior assistant conservator of forests, British Guiana.

Effect of Lightning Discharge

PROF. E. W. MARCHANT, 20, Harthill Road, Liverpool, 18, writes: "During a severe thunderstorm in Liverpool on July 31, the centre of the roadway was struck by lightning. The lightning discharge produced a crack about six feet long in the asphalte road surface near the centre of the road and close to a manhole cover, which, I understand, was open at the time of the storm. Six or seven pieces of melted tar were scattered over the road close to the crack. Heavy rain was falling at the time and the interesting thing about the discharge was that it struck the flat surface of the road, although, only thirty feet away on each side, were trees about twenty feet high."

Announcements

DR. ANDRÉ DANJON, director of the Paris Observatory, has been elected a member of the Section of Astronomy of the Paris Academy of Sciences, in succession to the late Dr. Henri Deslandres.

DR. W. A. MACFARLANE, director of fuel efficiency in the Ministry of Fuel and Power, has been lent by the Ministry to the Department of Scientific and Industrial Research for about two years for appointment as director of the United Kingdom Scientific Mission in the British Commonwealth Scientific Offices in Washington. He will also be attaché for scientific matters in the British Embassy. In accordance with arrangements made at the time of his appointment, the present director of the Mission, Dr. F. N. Woodward, is returning to the United Kingdom towards the end of the year.

THE Public Health and Municipal Engineering Congress and Exhibition will be held at Olympia, London, during November 15–20. Further information can be obtained from the Joint Hon. Secretary, 84 Eccleston Square, London, S.W.1.

THE twenty-third annual conference of the Association of Special Libraries and Information Bureaux (ASLIB) will be held at Ashorne Hill, near Leamington Spa, Warwickshire, during September 17–20. Further information can be obtained from the Secretary, ASLIB, 52 Bloomsbury Street, London, W.C.1.

THE Council of the Royal Society of Arts is offering, under the Thomas Gray Memorial Trust, the objects of which are "the Advancement of the Science of Navigation and the Scientific and Educational interests of the British Mercantile Marine", a prize of £50 for an essay on "The Applications of Radar to Navigation". Further information can be obtained from the Secretary, Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2.

The South African Journal of Science of March 1948 reports the Oudtshoorn meeting in July 1947 of the South African Association for the Advancement of Science. It includes the presidential address by Prof. H. H. Paine, "The World View of the Physicist", and the addresses of the sectional presidents. Of these, Prof. C. C. Gillie reviewed "A Century of Astrophysics", Dr. C. N. C. Hamilton dealt with "Coal", Prof. A. Quintanilha with "The Problem of Cotton Production in Portuguese Africa", Dr. C. S. Grobbelaar with "Anthropometry and its Role in South Africa", the Abbé H. Breuil with "Ancient Raised Beaches and Prehistoric Civilizations in South Africa", and J. D. Rheinallt Jones with "The Development of Central and Southern Africa", including a few suggestions for research and action on some of the problems common to these territories. A number of the papers read at the meeting are also printed.

Mechanism of the Oxidation of Gaseous Formaldehyde

RECENTLY, Axford and Norrish[1] have put forward a scheme for the oxidation of gaseous formaldehyde in the temperature range 325°–375° C. Though this scheme accounts for the experimental facts, we regard the proposed initiation reactions as unsatisfactory, for they suggest that formaldehyde is oxidized directly to formic acid, whereas it is highly probable that this does not take place in a single step. Our recent experiments on the oxidation of gaseous acetaldehyde[2] have led us to propose as an initiation process the reaction of an oxygen molecule with an acetaldehyde molecule to form the acetyl radical and the perhydroxyl radical (HO_2). If an analogous initiation reaction is postulated for the oxidation of formaldehyde, we have

$$\mathrm{HCHO + O_2 = HCO + HO_2}.$$

The formyl radical is thought to be unstable[3,4] above 100° C., and it can reasonably be assumed that at high temperatures it will split up rapidly to give carbon monoxide and hydrogen. Then our first step becomes

$$1.\quad \mathrm{HCHO + O_2 = H + CO + HO_2} \qquad k_1 \text{ initiation.}$$

The subsequent reactions we suppose to be the same as those put forward by Axford and Norrish,

$$\begin{array}{lll}
2. & \mathrm{H + HCHO = H_2 + CO + H} & k_2 \ \text{propagation-decomposition} \\
3. & \mathrm{H + O_2 + HCHO = H_2O + CO + OH} & k_3 \\
4. & \mathrm{OH + HCHO = H_2O + CO + H} & k_4 \\
5. & \mathrm{H + O_2 + HCHO = H_2O + CO_2 + H} & k_5 \\
6. & \mathrm{H + O_2} + X = \mathrm{HO_2} + X & k_6 \\
7. & \mathrm{H + O_2 + O_2 = HO_2 + O_2} & k_7 \\
8. & \mathrm{H + O_2 + wall = HO_2} & k_8
\end{array}
\begin{array}{l}
\\
\left.\begin{array}{l}\\ \\ \\ \end{array}\right\} \text{propagation-oxidation} \\
\left.\begin{array}{l}\\ \\ \\ \end{array}\right\} \text{termination}
\end{array}$$

Since the chains are started by reaction (1) and terminated only by reactions (6), (7) and (8) we have, following Axford and Norrish[1]:

$$k_1(\mathrm{O_2})(\mathrm{HCHO}) = k_6(\mathrm{H})(\mathrm{O_2})(X) + k_7(\mathrm{H})(\mathrm{O_2})^2 + k_8(\mathrm{H})(\mathrm{O_2})(S)/d$$

(for cylindrical vessels the ratio area/volume is $1/d$, approximately, so if (S) represents the surface activity per sq. cm., then $(S)/d$ is the surface activity per unit volume). From this we get

$$(\mathrm{H}) = \frac{k_1(\mathrm{HCHO})}{k_6(X) + k_7(\mathrm{O_2}) + k_8(S)/d}. \qquad (9)$$

For the equilibrium concentration of OH radicals we have

$$k_3(\mathrm{H})(\mathrm{O_2})(\mathrm{HCHO}) \doteq k_4(\mathrm{OH})(\mathrm{HCHO}).$$

Hence

$$(\mathrm{OH}) = k_3\,\frac{(\mathrm{H})(\mathrm{O_2})}{k_4}. \qquad (10)$$

Substituting for (H) from (9) into (10) we get

$$(\mathrm{OH}) = \frac{k_1\,k_3\,(\mathrm{O_2})(\mathrm{HCHO})}{k_4\{k_6(X)+k_7(\mathrm{O_2})+k_8(S)/d\}}. \qquad (11)$$

The rate of disappearance of formaldehyde is, therefore, given by

$$-\frac{d(\mathrm{HCHO})}{dt} = k_1(\mathrm{HCHO})(\mathrm{O_2}) + k_2(\mathrm{H})(\mathrm{HCHO}) + (k_3+k_5)(\mathrm{H})(\mathrm{O_2})(\mathrm{HCHO})+k_4(\mathrm{OH})(\mathrm{HCHO}). \qquad (12)$$

Substituting for (H) and (OH) from equations (9) and (11) we get

$$-\frac{d(\mathrm{HCHO})}{dt} = k_1(\mathrm{HCHO})(\mathrm{O_2})' + \frac{k_1k_2(\mathrm{HCHO})^2}{k_6(X)+k_7(\mathrm{O_2})+k_8(S)/d} + \frac{k_1(\mathrm{O_2})(\mathrm{HCHO})^2(2k_3+k_5)}{k_6(X)+k_7(\mathrm{O_2})+k_8(S)/d}. \qquad (13)$$

This is the same as equation (IV) given by Axford and Norrish on page 534 of their paper[1]; thus this modified scheme, also, accounts for the experimental results. It has, however, the advantage of a more clear-cut initiation step and also shows why one gets performic acid at low temperatures, for here the formyl radical will be stable and the following reactions can take place.

$$\begin{array}{llll}
\mathrm{HCHO} & +\mathrm{O_2} & = \mathrm{HCO + HO_2}. & (14) \\
\mathrm{HCO} & +\mathrm{O_2} & = \mathrm{HCOOO}. & (15) \\
\mathrm{HCOOO} & +\mathrm{HCHO} & = \mathrm{HCOOOH + HCO}. & (16)
\end{array}$$

This is analogous to the scheme which we are putting forward to explain the occurrence of peracetic acid in the low-temperature oxidation of acetaldehyde.

[4] Leermakers, J. A., *J. Amer. Chem. Soc.*, **56**, 1537 (1934).

ANY initiation process which will provide one of the chain centres responsible for the propagation reaction, and the rate of which depends upon the product of the pressures of formaldehyde and oxygen, may be substituted for that which we propose without change in the structure of the kinetics. It is thus not surprising that there is no formal change in the derivation of the relationship which Messrs. McDowell and Thomas reproduce from our paper. Initiation reactions, however, can be distinguished by studying the overall activation energy of the chain reactions which they initiate and to which they make the principal contribution, and in choosing the most likely initiation reaction, reference must be made to the thermochemistry of the processes postulated. Now the overall temperature coefficient of the oxidation of formaldehyde at 350° C. indicates an energy of activation of about 20 k.cal., and nearly all of this is associated with the initiating process, for which the velocity coefficient is k_1. Thus the initiation process at the temperature studied cannot be more endothermic than c. 20 k.cal., and is probably less so. From the data of Bray[1] we may derive

$$\mathrm{H + O_2 = HO_2} + 52 \text{ k.cal.};$$

and combining this with

$$\mathrm{H + HCO = H_2CO} + 102 \text{ k.cal.},$$

we may calculate that the reaction

$$\mathrm{H_2CO + O_2 = HCO + O_2}$$

is endothermic to the extent of 50 k.cal. Since this figure must give a lower limit for the energy of activation, it would appear that the reaction cannot function as an initiating process for the formaldehyde oxidation in the range of temperature where the overall energy of activation is 20 k.cal.

On the other hand, from the heats of combustion of formaldehyde and formic acid, and the heat of dissociation of molecular oxygen, we may calculate a heat absorption of about 8 k.cal. for the initiation process:

$$HCHO + O_2 = (HCOOOH) = HCOOH + O$$

postulated by us. This endothermicity is less than the energy of activation at 350° C. and is thus in accord with the experimental results.

Our initiation reaction involves the formation of performic acid as a transition compound, followed by its decomposition to give an oxygen atom; this would explain the occurrence of performic acid at the lower temperatures at which it is stable, and a similar scheme would give peracetic acid in the case of acetaldehyde. We have never supposed that the reaction takes place in a single step as suggested by Messrs. McDowell and Thomas. On the other hand, there is no case for dogmatizing, and we hope to get further evidence from a more detailed study of the temperature coefficient of the reaction. There are reasons for believing that more than one initiation reaction can operate, each in a different temperature range, without essentially changing the kinetic scheme we have derived, and at higher temperatures the alternative which has been suggested is not excluded.

Further Experimental Evidence for the Theory of Quasi-Properties

Scott Blair, Veinoglou and Caffyn[1] have explained the rheological behaviour of certain complex materials in terms of 'quasi-properties'; that is, complex entities in which a number of magnitudes taken together describes the process which the material undergoes as a result of a specified test, the ordinary 'properties', such as viscosity and elasticity, being changed by the testing process itself.

The simplest illustration of this is the Nutting[2] equation

$$\psi = S^{\beta}\sigma^{-1}t^{k}, \qquad (1)$$

where S is stress, σ is strain, t is time, and where ψ is a constant which can only describe the relative behaviour of materials when quoted in conjunction with k and β, which are numbers specifying its dimensions. In the limit, when β and k have constant values for large groups of materials, ψ approximates in character to a physical property of the ordinary kind.

Many materials subjected to constant compressive or tensile stresses or relaxing at constant strain after rapid straining accurately obey equation (1); but a few, especially when relaxation follows a slow straining, show considerable discrepancies.

In our earlier paper* we proposed 'intermediate' fractional differential equations of the type:

$$\begin{array}{l}\text{Proto-}\\ \text{types}\end{array}\left\{\begin{array}{l}\left.\begin{array}{l}\eta = S \div \dfrac{d\sigma}{dt}\\ n = S \div \sigma\end{array}\right\}\chi_1 = S^{\beta} \div \left\lceil\dfrac{\partial^{\mu}\sigma}{\partial t^{\mu}}\right. \quad (2a)\\ \left.\begin{array}{l}\eta = t \div \dfrac{d\sigma}{dS}\\ \pi = t \div \dfrac{\sigma}{S}\end{array}\right\}\chi_2 = t^{k} \div \left\lceil\dfrac{\partial^{\omega}\sigma}{\partial S^{\omega}}\right. \quad (2b)\end{array}\right\}\frac{1}{X} = \left\lceil\frac{d^{\mu+\omega}\sigma}{dt^{\mu}.dS^{\omega}}\right. \qquad (2)$$

where $\lceil$ indicates fractional differentiation. Equation (2a) may be integrated to give:

$$\sigma = At^{k} + Bt^{k-1} + Ct^{k-2}, \qquad (3a)$$

and it was shown that the great majority of those of our data which did not obey equation (1) could be accounted for by introducing the second term of equation (3a) and, in a few cases, the third term.

We have now examined the rest of the anomalous data and have fitted both the integrated form of equation (2b):

$$\sigma = A'S^{\beta} + B'S^{\beta-1} \qquad (3b)$$

as well as the general integrated form of equation (2):

$$\sigma = (At^{k} + Bt^{k-1}\ldots)(A'S^{\beta} + B'S^{\beta-1}\ldots). \qquad (3)$$

(The product is preferred to the sum of equations (3a) and (3b), though both are valid integrations of equation (2).)

In all the data examined, we have found that with no more than two terms in each case, either equation (3a), (3b) or (3) fits our data within the limits of experimental error, which are satisfactorily low.

Since the ratios B/A and B'/A' have the dimensions of time and stress respectively and represent characteristics of the materials, it should be possible to write the three equations in dimensionless form by expressing all times and stresses in terms of these characteristics. Deviations from the simple Nutting equation are rarely large enough, however, for such a procedure to give reasonable accuracy.

In our earlier paper we explained that the fractional differentials with respect to time arise as a result of the use of the Newtonian definition of equality of time units, the acceptance of which *defines* the velocity of light, or of bodies free from the influence of other matter as constant.

Just as the Newtonian time-scale depends on the constancy of the magnitude of such velocities, so it seems that Newtonian definitions of equality of forces, unless directly involving Newtonian time, must depend on the concept of a straight line or of unchanging direction, that is, the *course* of a light ray or of a body uninfluenced by other matter.

For example, two forces, X and Y, might be defined as equal when, acting in the same direction on a body, a third force, Z, can be found which would balance either of them so that the body would not change its motion as a result of the simultaneous actions of either X–Z or Y–Z. If the body is of finite size, X (or Y) and Z must be acting in a straight line: if the body becomes a point, there can be no change in direction at this point.

The implications of this in relation to the stress fractional differentials (equations 2b and 3b) are discussed in a paper in process of publication (*Phil. Mag.*), in which the full experimental results are also given.

Our indebtedness to several colleagues who have helped us is expressed in our paper itself. Here we wish to acknowledge our gratitude to the British

---

* The equations are here re-written in a slightly more convenient form.

Ionic Reactions in Liquid Dinitrogen Tetroxide

THE fact that liquids other than water may serve as media for inorganic reactions is widely recognized; reactions in the well-known liquid ammonia and liquid sulphur dioxide systems are explained by postulating the ionization:

$$2NH_3 \rightleftharpoons NH_4^+ + NH_2^-$$
$$2SO_2 \rightleftharpoons SO^{2+} + SO_3^{2-},$$

although neither liquid has an appreciable electrical conductivity. Frankland and Farmer[1] in 1901 first considered the possibility that liquid dinitrogen tetroxide might serve as an ionizing medium, but were unable to find any inorganic salt which was soluble in the liquid. In view of the high solubility of many organic compounds, they concluded that the liquid was of a non-ionizing character and resembled in behaviour such organic solvents as benzene.

We have now obtained evidence that ionic reactions can be conducted in liquid dinitrogen tetroxide medium. Where electron-transfer can readily occur, all reactions so far investigated in this medium can be interpreted on the basis of the ionization:

$$N_2O_4 \rightleftharpoons NO^+ + NO_3^-. \qquad (1)$$

The existence of the nitrosyl radical is already established in other media[2,3], and we have found no evidence for dissociation of the N_2O_4 into NO_2^+ and NO_2^- under these conditions. Thus the alkali metals, including lithium, react rapidly but quietly with liquid dinitrogen tetroxide to yield the nitrate and nitric oxide:

$$Na + N_2O_4 \rightarrow NaNO_3 + NO. \qquad (2)$$

The reaction is not affected, except in velocity, by dilution of the dinitrogen tetroxide with an inert solvent such as benzene. The insoluble nitrate produced is free from nitrite. At temperatures approaching the boiling point of dinitrogen tetroxide (21·3°) the nitric oxide is evolved (although at low temperatures, or under pressure, some nitric oxide remains associated in the liquid phase as blue dinitrogen trioxide), and the reaction can be considered as a simple electron transfer from the sodium atom to the NO^+ ion, giving the resonance-stabilized nitric oxide molecule. Attempts to explain this reaction on the basis of dissociation of the medium into NO_2^+ and NO_2^- would involve the intermediate formation of the alkali metal nitrite, which we have found to be stable in contact with liquid dinitrogen tetroxide. Although some metallic oxides when allowed to react with dinitrogen tetroxide yield nitrite as well as nitrate, this is probably at least a two-stage reaction which may be explained thus: $MO + (2NO^+ + 2NO_3^-) \rightarrow M(NO_3)_2 + 2NO^+ + O^{2-}$, followed by $MO + 2NO^+ + O^{2-} \rightarrow M(NO_2)_2$, and the formation of nitrite here does not necessarily imply the presence of NO_2^- in the medium.

Ammonium chloride (in liquid ammonia) and thionyl chloride (in liquid sulphur dioxide) have many properties commonly associated with aqueous hydrochloric acid solutions. The corresponding compound in the liquid dinitrogen tetroxide system, nitrosyl chloride, is soluble in this medium and such solutions attack many of the metals which are resistant to the tetroxide alone, the degree of attack depending on the concentration of the nitrosyl chloride; nitric oxide is evolved, the insoluble product being either the metal chloride or the chloride associated with nitrosyl chloride as a complex of the type $(NO)_x[MCl_y]$.

The ionic dissociation of dinitrogen tetroxide (equation 1) is fully reversible in the liquid phase. Thus the reaction:

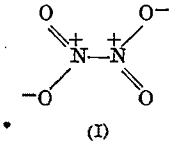
$$NOCl(\text{in } N_2O_4) + AgNO_3(s) \rightarrow AgCl(s) + N_2O_4(l)$$

(comparable with the reaction between an aqueous solution of hydrogen chloride and an insoluble hydroxide) is complete in the direction indicated. However, if dry diethylammonium chloride is added to liquid dinitrogen tetroxide at 0° the reaction:

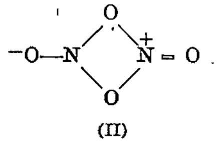
$$[Et_2NH_2]^+Cl^- + N_2O_4 \rightarrow NOCl + [Et_2NH_2]^+NO_3^- \qquad (3)$$

proceeds readily. The medium is immediately coloured red by the nitrosyl chloride produced, and diethylammonium nitrate may be crystallized from the solution; the process resembles that of hydrolysis. At higher temperatures the products of reaction (3) undergo further mutual interaction.

Full details of the work will be published elsewhere, but it is of interest here to compare the behaviour of dinitrogen tetroxide outlined above with its reactions where bonds of a covalent character are involved. Levy and Scaife[4] have shown that it adds to olefinic double bonds to give exclusively dinitro-compounds or nitro-nitrites. Again, both ammonia and diethylamine react explosively with it, yet ammonium and diethylammonium chlorides and nitrates are unattacked, so that the conversion of the base into the ionic form shields it from decomposition by dinitrogen tetroxide. We are led to the conclusion that the dinitrogen tetroxide molecule may undergo dissociation in two ways during reaction, giving either $(NO^+ + NO_3^-)$ or $(NO_2^+ + NO_2^-)$, and that the particular course followed depends upon whether the reacting groups are charged ions or covalent, uncharged molecules. It is not our desire here to support any particular structure for the dinitrogen tetroxide molecule; but our work on ionic reactions has shown that the molecule should be capable of dissociation into NO^+ and NO_3^- units as a result of simple electron transfer processes. Ingold[5] considers that the results of Levy and Scaife[4] provide additional and conclusive proof of structure (I).



(I)



(II)

Ionic dissociation of this molecule (equation 1) would involve the breaking of the N–O bond and transfer of the oxygen atom, whereas ionization of molecule (II) postulated by Longuet-Higgins[6] would involve no atom transfer, while at the same time satisfying physical evidence regarding symmetry[7].

A General Solution for the Force Constants of Polyatomic Molecules

IT is well known that the fundamental vibration frequencies of polyatomic molecules can be predicted with an error of only 1 or 2 per cent by solving the secular equation with force constants obtained from related molecules[1]. The reverse process of solving for the constants in terms of the frequencies is, in general, impossible unless some special assumptions are made concerning the force field[2]. The following general solution is therefore of some interest.

The nth order secular equation can be written in matrix form as follows:

$$|dA - \lambda I| = 0. \tag{1}$$

The elements of d are the force constants d_{ij} in the general potential function:

$$2V = \sum_{i=1}^{n} \sum_{j=1}^{n} d_{ij}\Delta_i\Delta_j. \tag{2}$$

The Δ_i are valence-type co-ordinates, expressed in terms of N further co-ordinates z_j:

$$\Delta_i = \sum_{j=1}^{N} a_{ij}z_j, \tag{3}$$

all possessing any required symmetry properties, and the elements of A (related to the inverse kinetic energy matrix G used by Wilson[3]), are defined as follows:

$$A_{ij} = A_{ji} = \sum_{k=1}^{N} a_{ik}a_{jk}\frac{M}{m_k}, \tag{4}$$

m_k being the mass for the co-ordinate z_k and M some arbitrary mass, introduced in order that the A_{ij} shall be pure numbers. I is the unit matrix, and the quantity λ is defined as follows:

$$\lambda = 4\pi^2\nu^2c^2M, \tag{5}$$

ν being the frequency of vibration in cm.$^{-1}$ and c the velocity of light in cm. sec.$^{-1}$. The (N–n) null vibrations factorize out, giving (1). If the subscripts are ordered so that Δ_i is the approximate normal co-ordinate for ν_i, corresponding to the vibrational assignment, and if $\nu_1 > \nu_2 \ldots > \nu_n$, then the proposed general solution for the constants is obtained by equating to zero all elements below the diagonal of the determinant (1), thus reducing it to the product of n linear factors, and substituting λ_1 to λ_n in order in the n diagonal elements; that is:

$$\left.\begin{array}{l} \sum\limits_{i=1}^{n} A_{ki}d_{ki} - \lambda_k = 0, \; (k = 1, 2 \ldots n). \\ \sum\limits_{i=1}^{n} A_{qi}d_{pi} = 0, \; (p > q). \end{array}\right\} \tag{6}$$

The corresponding (unnormalized) normal co-ordinates are given by:

$$z_i^{\nu_k} = \sum_{j=1}^{k} a_{ji}\frac{M}{m_i}\,{}^k|A|_{kj} \tag{7}$$

$$\Delta_p^{\nu_k} = \sum_{j=1}^{k} A_{pj}\,{}^k|A|_{kj}, \; (= 0 \text{ for } p < k). \tag{8}$$

where ${}^k|A|_{kj}$ are first minors of the kth order determinant formed from the first k rows and columns of the matrix A. The normal co-ordinate for ν_i involves only the co-ordinates Δ_i to Δ_n; the method, in effect, factorizes out the frequencies in descending order, the molecule increasing in rigidity as factorization proceeds. If only the constants for the m lowest frequencies are required, only elements in the last m rows of (1) need be considered, without introducing any fresh approximation.

The above solution is found to give surprisingly good results with actual examples, and is easy to apply. For molecules in which all the fundamentals fall into the category of 'group vibrations', factorization of the secular equation will clearly give a close approximation; where $(\nu_i - \nu_{i+1})$ is small and Δ_i and Δ_{i+1} overlap, the approximation will not be so close, since the normal co-ordinate for ν_{i+1} would then certainly involve Δ_i; but only the constants d_{ii}, $d_{i(i+1)}$ and $d_{(i+1)\,(i+1)}$ will be much affected. The constants obtained in (6) are always real, and the normal co-ordinates defined in (7) and (8) correspond to the vibrations having idealized geometrical forms; thus, in valence vibrations the atomic displacement vectors lie directly along the appropriate valence bonds. Interactions which would normally be discarded are here generally found to be negligibly small; their retention gives the unambiguous solution.

The method can obviously be adapted to predict vibration frequencies, by substituting constants only in the diagonal elements of (1); the inconsistency in the force field can then be estimated by evaluating terms below the diagonal.

Study of the Action of Ultra-violet Light on Urease by Means of the Ultracentrifuge

THE action of ultra-violet light on serum albumin has been studied with the ultracentrifuge by Svedberg and Brohult[1] and by Sanigar, Krejci, and Kraemer[2]. Irradiation of serum albumin at room temperature and at 0° C. causes the formation of low-molecular substances and a general inhomogenization of the protein.

It seemed worth while to perform a similar experiment with a protein having enzymatic activity in order to see if inhomogenization accompanies loss of activity, or is a process resulting from the absorption of quanta beyond those required on the average for inactivation. For irradiation, monochromatic light of 2537 A. was used, at which a quantum yield of inactivation of 0·000926 has been found[3]. Inactivation involves a 'one-hit' process, that is, only one quantum is required for inactivation, although many (1,100) quanta may be absorbed on the average without producing inactivation.

A solution (0·5 per cent) of crystallized urease, *p*H 7 in 0·02 *M* phosphate buffer, was sedimented at 60,000 times gravity. It gave a sedimentation constant, S_{20}, of 18·2 Svedberg units, with a heavier component, S_{20} equal to 27·5, present to the extent of about 20 per cent of the total protein. This compares within the experimental error with earlier results of Sumner *et al.*[4], who found S_{20} equal to 18·6 for the main component in their best preparation. After a loss in activity of 45 per cent by irradiation, a main component with S_{20} equalling 15·0 was present to the extent of 60 per cent of the main component of the control sample. Comparison showed an increase in the amount of material both lighter and heavier than the main component. In a second experiment the activity of one aliquot was reduced to 66 per cent by radiation, and of another aliquot to 63 per cent by heating in a water bath at 80°. After irradiation, a fairly sharp main component remained. Following heat denaturation, however, no clearly defined component was visible, the material having become extremely polydisperse and inhomogeneous.

These results show that the decrease in activity of the irradiated solutions was about equal to the decrease in concentration of the main component, and the average molecular weight of this component was somewhat decreased. This, together with the appearance of more heavy material, suggests that irradiation brings about a primary process of inactivation and depolymerization followed by aggregation of the depolymerized material. Adjustment of irradiated solutions to the isoelectric point is known to augment this second step by inducing precipitation[2]. That ultra-violet light is more specific in its action than is heat is also indicated. The latter agent produces a more general distribution of particle sizes resulting, doubtless, from a spectrum of energy which breaks bonds at random. Monochromatic light, however, which is selectively absorbed at aromatic residues[5], would tend to produce more well-defined fragments by breakage of bonds next to chromophores.

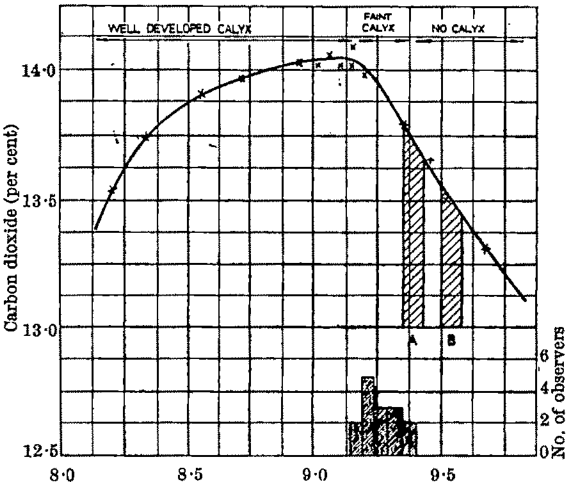
Use of the Calyx Burner to Determine Combustion Conditions

H. ROSTRON HINDLEY[1] has recently directed attention to the limitations of the calyx flame as an indicator of maximum carbon dioxide concentration in products of combustion. His letter seemed to us inconclusive, as the scale of air flow in the accompanying diagram was arbitrary and hence gave no indication of the magnitude of the possible error in terms of air/gas ratio. There was also no indication of the relation between the peak concentration of carbon dioxide and the theoretical mixture. It cannot be assumed that these two points would coincide under the combustion conditions prevailing in the calyx burner. As we had not previously considered the calyx flame as an indicator of maximum concentration of carbon dioxide, it was thought to be worth while making further tests with this application in mind.



Gas rate, 2·49 cu.ft./hr. throughout.
A, total air requirement calculated from analysis
B, ,, ,, ,, ,, using Wood's formula (lines indicate limits of probable error)

Using a calyx burner of the type described by Brinsley and Stephens, determinations of the total air requirement of Birmingham towns gas were made by three observers having considerable experience of calyx observation, one of whom was known from previous special tests to have sensitive colour vision. Comparison was made with twelve other observers used to scientific observations but having no special training in, or experience of, calyx observation. One of these observers was also known to have specially sensitive colour vision. At the same time a series of carbon dioxide determinations were made, and the total air requirements of the gas were calculated both directly from the gas analysis data and also using J. W. Wood's formula[2]. As an additional confirmation of the value of the maximum carbon dioxide concentration an analysis was made of the products of combustion from a Boys calorimeter and the carbon dioxide calculated on an oxygen-free basis. This confirmed the peak concentration shown on the full line in the accompanying diagram.

The point of disappearance of the calyx as determined by the two colour-sensitive observers fell consistently on the left-hand limit of the region marked 'no calyx'. The end points in the case of all the other observers except one fell between the right-hand end of the range marked 'well developed calyx' and the 'no calyx' limit. One observer had difficulty in seeing the calyx under any conditions. The frequency distribution of observations adjusted to a constant number of observations per observer is also shown on the diagram. Although the number of observers is insufficient to obtain a statistically valid distribution, this information is included for the sake of completeness. The extreme range of error in the determination of air/gas ratio was about ± 1·5 per cent, which is sufficiently accurate for most purposes connected with gas appliance design and with observations of gas quality.

It will be seen from the diagram that the end points of the two colour-sensitive observers agreed well with the values for the total air requirement calculated from the gas analysis data. The latter were definitely not coincident with the peak of the carbon dioxide curve.

A New Method for the Preparation of Adsorbents for Chromatography

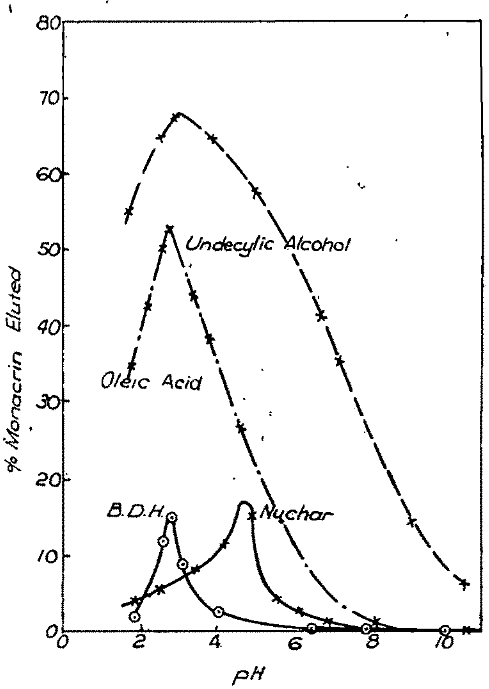
THE technique of chromatography, as used at present, is limited to a few adsorbents and usually to non-aqueous systems, due to the difficulty of elution of the adsorbate. However, aqueous systems could be used if adsorbents were available which permitted adsorption and desorption to be controlled by *p*H adjustment. This procedure is possible in some cases with synthetic ion exchange resins which have been used to a limited extent for the separation of mixtures of inorganic ions, organic bases such as thiamine, and some amino-acids. However, organic bases cannot always be recovered quantitatively even by elution with strong acids. 'Sodium cotton succinate' has been used for the quantitative adsorption and recovery of histamine, which could not be eluted quantitatively from ion exchange resins[1].

Activated charcoal has not generally been used for chromatographic separation of water-soluble substances because of its high adsorptive power and the subsequent difficulty of elution. It has been used for three-stage countercurrent adsorption of certain antibiotics such as penicillin, where an organic solvent is used for elution, followed by an additional extraction into buffered solution.

By adsorption of a surface-active or water-insoluble acid, for example, fatty acids or lecithin, as a 'primary' adsorbate, on adsorbents such as alumina, activated charcoal, or even carbon black, I have prepared a simple and versatile adsorbent similar in behaviour to an ion exchange resin. The adsorbent acquires the properties of the 'primary' adsorbate, and forms, under alkaline conditions, salts with cations or bases which may be considered as a 'secondary' adsorbate. The 'secondary' adsorbate can be eluted by acid solution. This eliminates the use of organic solvents and permits the immediate re-use of the prepared adsorbent.

Cationic surface-active agents, or insoluble bases, may be used in place of the fatty acids as a 'primary' adsorbate to prepare adsorbents for acids or anions. Similarly, the 'primary' adsorbate may be any substance that can form a complex with the materials to be separated or fractionated; for example, the lignin protein reaction might be utilized for the fractionation of some protein mixtures.

Typical curves for the adsorption of 'Monacrin' (5-amino acridine) directly on 'Nuchar' and B.D.H. decolorizing charcoal (reproduced herewith) are in agreement with the findings of Hauge[2], Olin[3] and Sastri[4], who showed that the adsorption of electropositive substances on activated charcoals is a minimum in the region of a characteristic *p*H termed the isoelectric point.



0·05 gm. adsorbent; 10 ml. 4 × 10^{-3} *m/L* 'Monacrin'

A similar curve is also shown for the adsorption of 'Monacrin' on B.D.H. charcoal pretreated with 20 per cent of its weight of oleic acid. Two distinct adsorption processes occurred. The curves indicate that above a *p*H value of approximately 6, the 'Monacrin' reacted with oleic acid to precipitate an insoluble salt on the adsorbent. In this *p*H range the salt formation was the principal adsorption mechanism, and strong adsorption was observed for both strong and weak adsorbents, such as B.D.H. charcoal and acetylene black. Below this *p*H-range, free base was liberated from the salt and was apparently adsorbed on the oleic acid layer, the degree of adsorption depending on the adsorptive power of the carbon. Thus B.D.H. charcoal showed a minimum adsorption amounting to 50 per cent of the 'Monacrin' at *p*H 3·0, whereas acetylene black similarly treated with oleic acid showed practically complete elution. Increasing the amount of adsorbed oleic acid in the pretreatment reduced the 'Monacrin' adsorption.

By selecting a carbon with a suitable isoelectric point, and an acid or base of the required strength, a great variety of exchange adsorbents can be prepared. For single-stage adsorptions, quantitative adsorption and elution of the adsorbate are desirable, and may be achieved by using a weak adsorbent such as acetylene black coated with oleic acid. Chromatographic separations require a stronger adsorbent to permit development.

The adsorption is also shown in the accompanying graph, under the same conditions, of 'Monacrin' on B.D.H. charcoal pretreated with 40 per cent of its weight of undecylic alcohol as 'primary' adsorbate. In this case salt formation cannot occur, and the 'Monacrin' is bound by adsorptive forces only, which appear to be electrostatic in nature[5]. Thus any factor which varies the dielectric constant of the 'primary' adsorbate film, and hence the surface charge, might be expected to alter the degree of adsorption. In this manner, a great variety of adsorbents may be prepared.

This work will be discussed in detail in a paper to be published elsewhere.

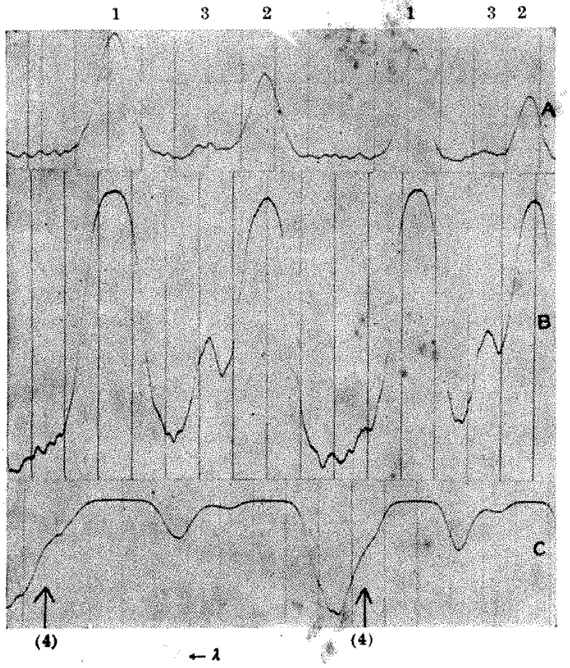
Fine Structure of the Hydrogen α-Line

Though the doublet structure of the Balmer lines has been known for sixty years, attempts at a more complete resolution of the fine structure have met with difficulties owing to the large Doppler width of the individual lines. In the α-line, a third component arising from the transitions $2S_{1/2}$–$3P_{1/2}$ and $2P_{1/2}$–$3S_{1/2}$ was resolved by Williams[1] in 1938, using a deuterium discharge tube in liquid air; but the resolution was not complete enough to allow an accurate measurement of the positions of the components. From these results, Pasternack[2] deduced a displacement of about 0·03 cm.$^{-1}$ of the $2S_{1/2}$ level from its position given by Dirac's theory. This value was no more than a rough estimate, and only through the microwave experiments of Lamb and Retherford[3] was the reality of the shift established.

By using a deuterium discharge tube immersed in liquid hydrogen and run at very low current densities ranging from 2 to 6 milliamp. per sq. cm., we have been able to resolve the third component much more completely, and under conditions where the relative intensities are in qualitative agreement with the theoretical prediction for undisturbed atoms. Fabry-Pérot étalons with spacings of 5 mm. and 7·5 mm. were used.



The photometer tracing *A* shows the main components (1) and (2), the latter appreciably weaker as predicted by the theory. Tracing *B*, of a plate with longer exposure, shows the component (3) well resolved from (2). As the result of measurement of thirty-six fringes in eleven different exposures, the spacing (3)–(1) was found to be 0·183 ± 0·005 cm.$^{-1}$.

Though each of the three components is a blend of two unresolved lines, in both (1) and (3) one of the two constituent lines is so weak that its presence has only a small influence, a rough estimate of which is sufficient. With these corrections, our results lead to an upward displacement of the $2S_{1/2}$ level of 0·043 ± 0·006 cm.$^{-1}$.

This value does not agree well with the shift of 0·033 cm.$^{-1}$ found by Lamb and Retherford. These authors do not apparently claim great accuracy for their measurements; but an error of more than 10 per cent would have to be assumed to make them compatible with our results. The values of the radiation shift of the $2S_{1/2}$ level calculated by Bethe[4] and Dyson[5] are 0·033 and 0·034 cm.$^{-1}$, which agree with Lamb and Retherford's measurements, but not so well with ours.

With very long exposures, we have also been able to resolve and to measure a fourth component due to the transition $2P_{3/2}$–$3S_{1/2}$. On account of its small intensity, it had not hitherto been resolved from the fifty times stronger component (1). It can be seen in tracing *C*, in which the other lines appear broadened by over-exposure. The separation (1)–(4) was found to be 0·138 ± 0·006 cm.$^{-1}$.

The measurement of this new component allows the position of the term $3S_{1/2}$ to be determined. The value 0·138 of the separation (1)–(4) would give the position of the $3S_{1/2}$ term in almost complete agreement with Dirac's theory (only 0·003 cm.$^{-1}$ higher), whereas Bethe's theory predicts an upward shift of 0·011 cm.$^{-1}$. On account of the incomplete resolution, however, we do not claim that our value for this term is completely certain.

Further work is being done in an effort to achieve better resolution.

We are greatly indebted to Prof. F. Simon and his co-workers for the supply of liquid hydrogen.

Photodisintegration of Deuterium and Beryllium by Thorium C″ γ-Rays

The ratio has been measured between the numbers of neutrons emitted from sources made by placing 300 mC. of radium–thorium in the centre of spheres of heavy water and beryllium respectively. These sources emit neutrons according to the well-known reactions:

$$\mathrm{H}_1^2\,(\gamma,n)\,\mathrm{H}_1^1 - 2\cdot18\ \mathrm{MeV}. \qquad (1)$$

and

$$\mathrm{Be}_4^9\,(\gamma,n)\,\mathrm{Be}_4^8 - 1\cdot63\ \mathrm{MeV}. \qquad (2)$$

$$[\mathrm{Be}_4^8 \rightarrow 2\mathrm{He}_2^4 + Q].$$

Since thorium C″ emits a γ-ray of 2·62 MeV. energy, this leads to neutron energies of 0·22 MeV. and 0·80 MeV. respectively.

The heavy water used was of 99·6 per cent purity and was contained in a lead glass sphere 5 cm. in diameter with a cylindrical space 9 mm. long and 7·5 mm. diameter at the centre to contain the radium–thorium capsule. The beryllium was a machined sphere of pure beryllium metal 11 cm. in diameter, with a central cylindrical space 7·5 mm. long and 6 mm. in diameter. The relative numbers of neutrons emitted from these sources have been measured by slowing them down in a large tank of water and integrating the slow neutron density set up in this tank by using manganese foil detectors, the β-activity of which is afterwards measured by means of a Geiger counter with a thin aluminium wall. This ratio is

$$N_{\mathrm{Be}}/N_{\mathrm{D}} = 1\cdot26 \pm 0\cdot03.$$

From this ratio, and the data above, the ratio between the photo-disintegration cross-sections for beryllium and deuterium for a γ-ray energy of 2·62 MeV. energy can be calculated, a correction being applied for absorption of γ-rays in the deuterium and beryllium, making use of the absorption coefficients given in the "Handbook of Physics and Chemistry". The ratio then becomes

$$\frac{\sigma(\gamma n)\mathrm{Be}}{\sigma(\gamma n)\mathrm{D}} = 0\cdot35 \pm 0\cdot01,$$

a value in good agreement with the recently published work of Russell, Sachs, Wattenberg and Fields[1], who found values for $\frac{\sigma(\gamma n)\mathrm{Be}}{\sigma(\gamma n)\mathrm{D}}$ of 0·30 at 2·50 MeV. γ energy, and 0·43 at 2·76 MeV. γ energy.

A second determination was made using a 'long counter'[2] instead of a water tank to compare the neutron output of the two sources. These measurements give a value

$$\frac{\sigma(\gamma n)\mathrm{Be}}{\sigma(\gamma n)\mathrm{D}} = 0\cdot36 \pm 0\cdot03,$$

in good agreement with the first method.

Cold Working of Aluminium at Low Temperatures

AT the suggestion of Prof. J. Reekie of the University of Toronto, I have carried out a few experiments on the cold working of aluminium at room and liquid air temperatures. These show that although the metal is spontaneously self-recovering during cold working at room temperatures, it shows lattice distortion effects if the plastic deformation is carried out at the temperature of liquid air and the specimen is maintained at that temperature. The aluminium used was 'H.S.' brand, supplied by Messrs. Johnson Matthey and Sons, Ltd. The X-ray back-reflexion method was chosen for investigation of lattice distortion.

An aluminium rod with quite small crystals was first cold-worked by striking with a centre punch at room temperature. X-ray back reflexion pictures taken before and after cold working showed that the radial breadth of the rings in the X-ray pattern did not increase. The aluminium was then brought to the temperature of liquid air, when a third photograph was taken. This showed no line broadening. With the specimen at the low temperature the aluminium was again cold-worked. The rings were now considerably broadened. On allowing the specimen to warm up to room temperature, it was found that the line broadening disappeared and large spots on the rings indicated the process of recrystallization.

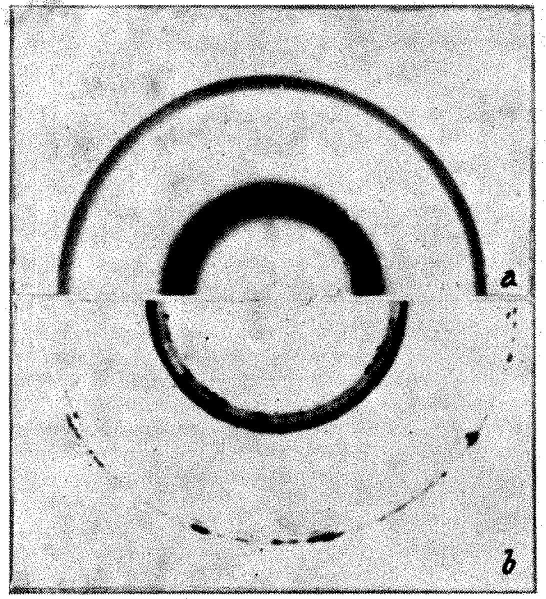

Fig. *a* shows the line broadening of the [420] and [331] rings on cold working at −180° C., while Fig. *b* shows the sharpening of the lines and the appearance of large crystals on allowing the specimen to warm up to room temperature. Cobalt *K* radiation was used in both cases.

The possible causes of general line broadening are: (1) variation of interplanar spacings in the metal due to variations in composition; (2) thermal fluctuations during the time of exposure; (3) small crystallite size; (4) variation of interplanar spacings due to mechanical strain. Causes (1) and (2) may be ignored because of the purity of the aluminium and the absence of line broadening with an unworked specimen photographed at −180° C. It is impossible on the evidence available to differentiate with any certainty between (3) and (4). The line broadening due to the fine-grain effect is given by the Scherrer formula $\Delta B = 0\cdot9\lambda/t\cos\theta$, where λ is the wave-length used, t the linear particle size and θ the Bragg reflexion angle. In the present experiment this would give an increase of just less than 1 mm. in the [420] ring with cobalt K radiation if the crystallite size decreased from about 10^{-4} cm., when the rings become continuous, to 10^{-5} cm. Now Wood[1] concludes that the lower limit of crystallite size produced in aluminium by very severe cold working is about 10^{-4} cm. On such a view the present line broadening of more than a millimetre would appear to be mostly due to mechanical strain.

There was no evidence in the present short series of experiments of the impossibility of producing complete rings after cold working, which was also noted in Wood's paper. Further work on this latter point will have to be done before a definite conclusion can be given.

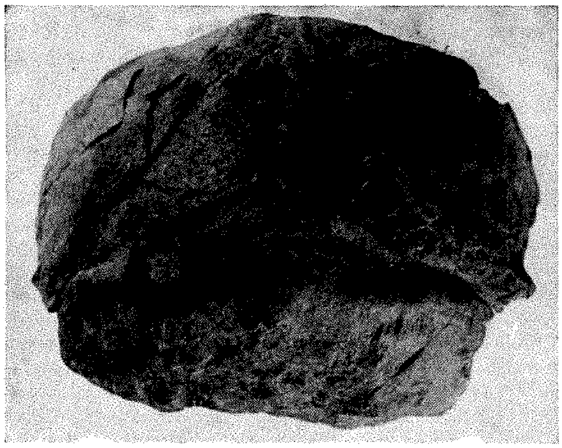
A (?) Promethean *Australopithecus* from Makapansgat Valley

During 1947 the Bernard Price Foundation for Palæontological Research in the University of the Witwatersrand maintained an archæological party in the Makapansgat Valley, twelve miles north-east of Potgietersrust. Their principal objective was to excavate the Cave of Hearths, a site of human habitation containing palæoliths of Chell-Acheul facies embedded in limestone breccia.

About a mile lower down the same valley is the Limeworks site where no implements have been found and from the dumps of which students and members of the staff of the Anatomy Department have been recovering primate and other mammalian fossils for several years past. The presence of *Parapapio broomi*, Jones, in the lowest stratum of the Limeworks cavern breccia shows that this earliest stratum belongs to the same geological horizon as that of Sterkfontein. Consequently it was a happy confirmation of our expectations when Mr. James Kitching came across an australopithecine occiput in this type of breccia during September 1947, while searching among the Limeworks dumps.

The new occiput (see photograph) exhibits an *Australopithecus* comparable in brain size to *Paranthropus robustus*, Broom, from Kromdraai. Owing to partial synostosis of the sagittal and lambdoid sutures the cranial fragment comprises the major portion of the occipital bone including most of the right margin of the foramen magnum and the posterior third of each parietal bone. It displays several significant humanoid anatomical features, namely, an expanded planum occipitale; an inferior situation of the inion relative to the opisthocranion and a consequent downward deflexion of the planum nuchale (thus proving the upright posture); the existence, but moderate development, of a torus transversus occipitalis (thus indicating the lack of a gorilloid 'bullneck' in the type) and the presence of a sutura transversa occipitalis (or sutura mendosa) with subsidiary sulci forming a complex 'Inca' bone (which has never been found hitherto in anthropoids).



Australopithecine occiput from the Makapansgat Valley

In all these features the Makapansgat *Australopithecus* distinguishes itself from its smaller-brained contemporary *Plesianthropus* at Sterkfontein. Further, if *Paranthropus* is geologically more recent (as Broom believes), the Makapansgat type probably differed considerably from *Paranthropus*. The final answer to this question must await the discovery of further remains.

But the most potent reason for separating the new fossil from its relatives is the difference between the bone breccia of Makapansgat Limeworks on one hand and the bone breccias of all the other manape sites on the other. The breccia shows first that the Makapansgat *Australopithecus* had advanced hunting habits and secondly that it was acquainted with the use of fire. Both of these inferences from the breccia were announced nine months before the discovery of the occiput in a communication to the First Pan-African Congress of Prehistory at Nairobi in January, 1947. They are briefly recapitulated here to explain why the name, *Australopithecus prometheus*, has been given to this specimen.

In addition to the Sterkfontein types of baboons such as *Parapapio broomi*, Jones, and *Parapapio jonesi*, Broom, the Makapansgat breccia has yielded fourteen species of Bovidæ, eight of which appear to be new; three carnivores (namely, lion, hyena and jackal); two extinct pigs; a rhinoceros; a hippopotamus; and two giraffes (including the extinct *Griquatherium*). Thus apart from the elephant we have concrete evidence that these creatures drew upon every family of big game found in Southern Africa for their food supply. The dentitions of the big game specimens, however, show that these Australopithecines were more frequently successful in slaying juvenile and aged representatives of these various mammalian families. But the profusion of the bone breccia shows that they were capable and successful in their hunting of very big game.

In 1925 the presence of *Australopithecus* was unsuspected because of the great size of these bones and their charred appearance—so the specimens of this Makapansgat Valley Limeworks bone breccia were submitted to two chemists (Drs. Moir and Fox) for analysis to discover whether the bones had been subjected to fire. From the great size of the beasts represented in the breccia, the intentional fracturing or splitting of the bones, and corroborative reports of the chemists relative to the presence of carbon, the deposit was claimed at that time as a primitive human kitchen midden. To-day it appears that all this 'human' activity at Makapansgat Limeworks site is the handiwork of man's australopithecine predecessors. No traces of stone implements have been found in the Makapansgat Limeworks strata nor have they been found at Taungs, Sterkfontein and Kromdraai. But we have found at Makapansgat a number of large ungulate humeri the epicondylar ridges of which were battered and broken and apparently as the result of deliberate use prior to their fossilization. Most of the bones are fresh and firm, and display clean clear lines of gross fracture before fossilization, but others crack and crumble easily. These exhibit so fine a state of macroscopic and microscopic cracking as to preclude explaining their pre-fossilization fragmentation by the crude impact of stone or bone. The most likely force to have been responsible for their crumbling and altered condition is heat. That fire was the splintering agent is corroborated by their discoloration, disintegration and the chemical reports of free carbon made more than twenty years ago, and by the vesicular character of the adjacent glassy collophanites and clays recently discovered in the breccia by Dr. V. L. Bosazza and the comparative analysis he has made of ashy deposit from the breccia with ash from local Transvaal wood.

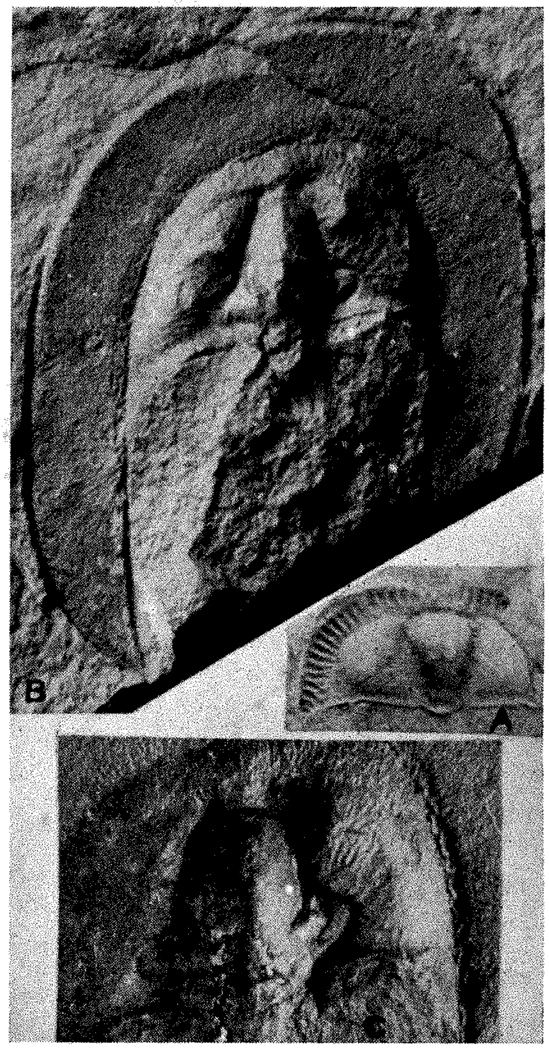
Indications of Cephalic Sutures in Trinucleidæ and Harpedidæ

RUDOLF RUEDEMANN[1] in 1916 summarized the available evidence regarding traces of cephalic sutures in Trinucleidæ, Raphiophoridæ, Dionididæ, and Harpedidæ. The well-known marginal sutures in the first and last families he considered as secondary acquisitions. They are generally regarded as having facilitated ecdysis; but specimens are rarely found which have fractured along them. One might even draw a comparison between the marginal suture, which is nearer the dorsal than the marginal side of the brim, and the subcranial furrow of *Phacops* (*s.s.*). Ruedemann's reconstruction, especially of the anterior facial suture, from traces on internal moulds, is so interesting in the case of *Cryptolithus tesselatus* Green, in spite of P. E. Raymond's treatment[2] of the lateral eye-lines as genal cæca and not lateral parts of a facial suture, that for a number of years a look-out has been kept for corresponding evidence on the eastern side of the Atlantic.

In the case of *Cryptolithus* the search has not been rewarded; but in a number of internal moulds of *Trinucleus fimbriatus* Murchison, symmetrical breaks have been observed. For the most part only the remains of lateral (or posterior) facial sutures can be traced[3], but in a specimen recently obtained from Llan Fawr Quarry, near Llandrindod Wells, a semicircular anterior facial suture appears to be present and to run just outside the anterior pits and forward into the fringe so as to enclose a number of pits of the innermost concentric row. This is different from what happens in *C. tesselatus*, in which Ruedemann makes the anterior facial suture pass inside the anterior pits and not cross into the pitted part of the fringe.

It is important, as shown in Fig. *A*, that the posterior parts of the suture are continuous with the anterior suture in *T. fimbriatus*. In *C. tesselatus* the genal cæca (Raymond) or lateral sutures (Ruedemann) do not join the frontal facial suture. So far as traces of facial sutures count, *Cryptolithus* seems to be further from the Opisthoparian ancestor than *Trinucleus*, and it may be suggested that in species which ploughed through mud the tendency was for the anterior suture to migrate away from and not towards the periphery of the fringe or brim.



A. Trinucleus fimbriatus Murchison, Llan Fawr Quarry (*Nemagraptus gracilis* Zone), north of Llandrindod Wells, × 2. *B. Scotoharpes domina* gen. et. sp. nov., *Plectodonta* aff. *canastonensis* Siltstones, North Esk, Pentland Hills, × 3 (approx.). *C.* Part of the specimen shown in *B*, × 4

Good observations of posterior facial sutures have been made in *Scotoharpes domina* gen. et sp. nov., from fine Upper Gala silts of the Pentland Hills. On an external impression of the cephalon, a possible longitudinal suture was seen crossing the posterior border close to the glabella and running forward near the proximal side of an ala, where it was joined at right angles by a lateral suture bisecting the ala. This is even clearer on the internal mould (Fig. *B*, right side). Further examination suggests that the longitudinal suture cuts across the anterior extremity of the ala (Fig. *C*, right side). Perhaps its continuation is indicated by a scar which diverges outwards on the cheek towards the distal end of the genal cæcum. Possible traces of an anterior suture cannot be treated with certainty; but in Fig. *C* (left side) a fine ridge, indicating a furrow on the inside of the original cephalic shield, runs forward and then curves inwards towards the position of the first lateral furrow on the glabella. Attention may also be directed to the slight transverse angularity just in front of the glabella and even to the anterior furrow itself which separates inner and outer parts of the cheeks. Laterally this furrow is shallow, and on the left side where it approaches the distal end of the genal cæcum (Fig. *B*) a curvilinear raised ridge originates which runs back and then bends inward slightly to meet the posterior border. Can this conceivably mark the position of an early lateral or posterior suture at a stage when *Scotoharpes*, at least ancestrally, showed affinities with a genus like *Aulacopleura*? The possibility of such a relationship is supported by the recent work of Přibyl[4], in the general background of that by Stubblefield[5]. The definite suture close to the sides of the glabella suggests the condition in Olenidæ and Prœtidæ. *Prœtus loredensis* Delgado, in particular, has recently been compared with the Harpedidæ[6].

Ruedemann has suggested that the evolution of a genus like *Cryptolithus* has been marked by great lateral development of the cheeks. It is to this he attributes the length and parallelism of what he calls the "lateral facial sutures". While this may be true, one must also consider the likelihood of eyes migrating inwards and upwards on to the highest parts of the cheeks in a mud-dweller. Even if functional eyes were afterwards lost, the tendency for the migration towards the glabella appears to be supported by the course of the sutural traces in *Trinucleus fimbriatus*. Migration of eyes inward, possibly from the position of slight depressions behind the outer ends of the genal cæca in *Scotoharpes domina*, also may be arguable.

It is not easy to answer the question as to why traces of what may be facial sutures should remain on the inside of a cephalon of *Trinucleus fimbriatus*, unless they continued to serve as lines of easy splitting. In *Scotoharpes* the lateral and posterior sutures were evidently functional, and their presence on the alæ may mean that the latter had a sensory function during ecdysis and perhaps at other times.

Changes in the Incisor Teeth and Incisal Alveolar Bone of Rats in Hypervitaminosis A and Avitaminosis A

THE changes in bone in avitaminosis A have been reported by Mellanby[1], Wolbach and Bessey[2], and Wolbach[3], who consider that the vitamin is concerned with the control of bone modelling. Mellanby found excessive formation of bone in certain areas during avitaminosis and that the osteoblasts and osteoclasts could reverse their positions at the effective bony surfaces. Wolbach[3] considered that appositional bone formation continued in the normal site, but that concurrent resorption of bone ceased. Excessive doses of vitamin A have been found by many writers to cause spontaneous fractures of bones and internal hæmorrhages (see Moore and Wang[4] for a review of the literature). Wolbach[3] considered that bone remodelling was greatly accelerated and that a defective tissue was laid down.

The effects of vitamin A deficiency on the teeth are already well known[5]. A defective dentin is laid down by the odontoblasts, especially on the labial side. Pohto[5] and Wolbach[3] both reported that hypervitaminosis A has no effect upon the rat's incisor teeth.

Through the kindness of Dr. T. Moore and Mrs. S. E. Walker, of the Dunn Nutritional Laboratory, Cambridge, I obtained the heads of animals suffering from hypervitaminosis A. These were young rats and had been given 40,000 I.U. of vitamin A daily for 10–42 days. Their incisal alveolar bone and upper incisor teeth were examined microscopically. In the alveolus, the rate of bone formation was greatly reduced, many cementing lines were seen and active osteoblasts were much less prominent than usual. Osteoclasts appeared to be unaffected, so that the bone became abnormally thin and disappeared in places. In the teeth, only dentin formation was affected. This became decreased in appositional rate, the interfibrillar cementing substance was gradually reduced in amount, and the lingual odontoblasts had begun to atrophy.

The avitaminotic material studied was from rats previously investigated (Irving and Richards[5,6]). The animals had been on the vitamin-free diet used by us 28–53 days from weaning. The alveolar bones showed considerable over-production of new bone. This occurred in areas where apposition was usually seen and also in situations where resorption normally occurred. In the early stages of the deficiency, the osteoclasts endeavoured to overcome the latter abnormal apposition, while working alongside invading osteoblasts. Later they became displaced by osteoblasts and some osteoclasts were found on the opposite side of the bone. On faces where excessive apposition occurred in the usual site for apposition, osteoclasts were never found. The changes in the teeth in avitaminosis were the same as those reported by earlier workers.

It is concluded from these results that the primary action of vitamin A is upon the osteoblasts. Excessive dosage with vitamin A depresses the action of these cells, and, when the vitamin is lacking from the diet, these cells engage in disorderly overactivity. The reactions of the osteoclasts in avitaminosis are purely secondary, in an attempt to prevent excessive bone formation. In hypervitaminosis A these cells continue to act as usual. The odontoblasts, cells in the teeth comparable to the osteoblasts, react in a way similar to that of the bone-forming cells, producing less dentin in hypervitaminosis and excessive amounts in avitaminosis.

The expenses of this work were defrayed by grants from the South African Council for Scientific and Industrial Research and from the Staff Research Fund, University of Cape Town.

Marine Fish Cultivation

IN their recent review in *Nature*[1] of the papers on an experiment in marine fish cultivation by my colleagues and me[2], Cooper and Steven express the view, "that encouragement of fish growth in arms of the open sea such as the North Sea or the English Channel by the addition of plant nutrients can never be a paying concern". This categorical statement, based on a previous paper by Cooper[3], seems to bar once and for all any large-scale application of fertilizers to suitable parts of the sea. Leaving a fuller discussion to a forthcoming paper on fertilizer application in an open sea-loch, may I point out here that Cooper's arguments and figures do not, in my opinion, bear out his conclusion. For an assessment of the economics of fertilizing the sea we require figures showing: (*a*) the return in crop and stock per ton of fertilizer added to land, (*b*) the return in fish and shell-fish per ton of fertilizer added to the sea. The latter figures unfortunately do not exist. If our experiments have shown anything, it is the desirability of keeping an open mind to a rational approach to the whole problem of increasing the amount of human food growing in the sea, and pursuing research step by step along various lines, not excluding the fertilizing of suitable larger areas. As regards the threatening scarcity of phosphate, should it become necessary to recover it from the sea it may prove possible to extract it from water taken from greater depths of unproductive areas where the concentration of phosphate is high and its availability to plants low.

F. GROSS

[3] Cooper, L. H. N., *J. Mar. Biol. Assoc.*, **27**, 326 (1948).

WE do not agree that the expression of a view is a "categorical statement" barring any door to further research. Be that as it may, we still consider that no evidence has yet been produced in support of the belief that encouragement of fish-growth by artificial fertilization of arms of the open sea, such as the English Channel or North Sea, can be made a paying concern. On the other hand, there is no little evidence in support of the opposite view. Perhaps the most convincing is the failure of Dr. Gross and his colleagues to demonstrate that marine fish cultivation could be made to pay even in a very tiny and almost completely enclosed body of water.

A large-scale fertilization of the sea is continuously in progress, for our method in the most advanced countries of disposing of the sewage of coastal towns achieves just this. The discharge from Plymouth, which must be considerable, affects the nutrient content of Plymouth Sound but is soon dissipated in the open sea beyond the breakwater. Its effect on the English Channel has rarely been notable. The problem would be most easily studied in an area already nutrient-poor, such as the Mediterranean and its adjacent seas. Such studies by Bernard[1] off Monaco and off Banyuls near the Franco-Spanish frontier, and by Ercegović[2] and Nümann[3] in the shallow northern Adriatic, do not seem to have found any appreciable enrichment by sewage. A quantitative assessment of the effect of sewage from large coastal cities discharging into seas of low natural nutrient resources should provide the readiest means of testing Ritchie's thesis which Gross again propounds.

Though there is a continuing exchange of the waters of the English Channel or the North Sea with the Atlantic Ocean, it is not easy to place a measure on it; it would seem to be large. The work of Proudman[4] suggests that the Irish Sea empties itself through the North Channel and is replaced through the St. George's Channel in a very few years, perhaps no more than two. The phosphate to be added to such arms of the sea, to do any good, would need to be measured in thousands of tons per annum. That part not quickly harvested as fish would vanish into the ocean in a year or two. Though it seems true that four-fifths of the phosphate added to arable land becomes tightly bound in the soil complex, some of it is still available to plants such as lupins which can get it out again; and given time enough, may not a saturation value be reached beyond which phosphate added to the soil remains freely available to plants? Be the answer to this what it may, there is a difference between immobilizing riches in a safe deposit and broadcasting them throughout the five oceans.

As to the last sentence of Dr. Gross's letter, it is always dangerous to try to foretell scientific development. Though the phosphate and nitrate resources of the deep ocean are enormous, the concentration rarely exceeds 90 μgm./l. of phosphate-phosphorus, or $0{\cdot}000003\ M$. In the near future, no engine devised by man is likely to harness this reserve better than the vast oceanic circulation and upwelling impelled by winds on a global scale, followed by production of plants and animals. Fisheries in the most favoured regions provide the best means yet known or foreseen of exploiting this natural asset. Our heritage of bird guano and rock phosphate, upon which we are so dependent, represents the final stages of this process of enrichment of surface ocean water by upwelling of deep water. This heritage is being replaced more slowly than it is being spent; we ought not to hasten the wastage.

We do not wish to bar any development once and for all. Economic justification of marine research can come only from the application of our increasing knowledge to problems of production from the sea. None the less, fervid advocacy of a very costly programme, followed by practical failure, could only bring the science of the sea into ill repute. Surely the right approach is through small-scale experiments to larger ones, establishing firm experience as we go. The Loch Craiglin experiment on these lines was thoroughly sound and worthy of critical appreciation. This we attempted in our review.

ARCTIC AEROBIOLOGY, II

PRELIMINARY REPORT ON FUNGI AND BACTERIA ISOLATED FROM THE AIR IN 1947

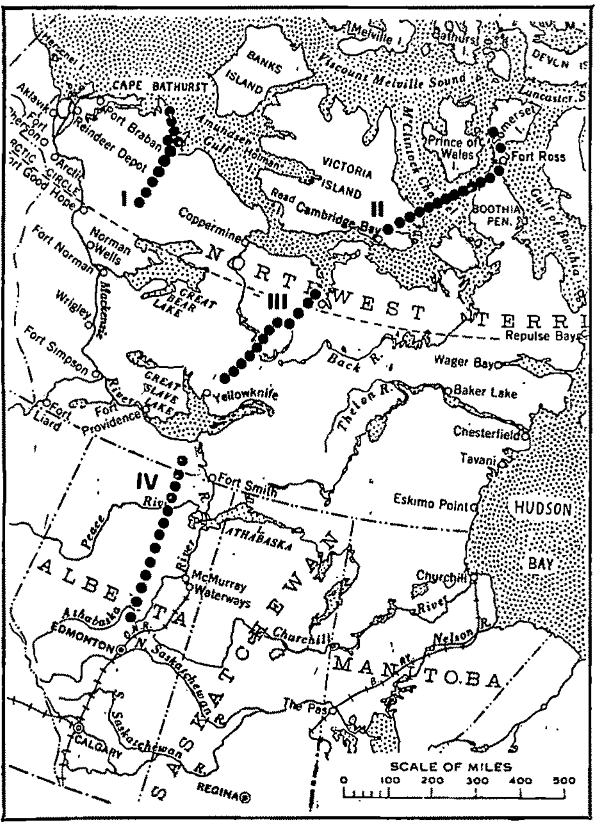
By Dr. S. M. PADY
Department of Botany

Dr. C. D. KELLY
Department of Bacteriology

AND

Prof. NICHOLAS POLUNIN
Department of Botany
McGill University, Montreal

ALTHOUGH many studies have been made of the microflora of the air over temperate regions, little such work has been done in the Arctic. Meier and Lindbergh[1] made some preliminary studies by exposing petrolatum-coated slides at various points during Lindbergh's northern flight in 1933, six of these exposures being north of the Arctic Circle over Greenland. Owing to the death of Dr. Meier, only a brief report was published[2]. The following account presents the results of a series of exposures of nutrient plates in arctic and subarctic Canada in 1947, and also preliminary studies of the subcultures of bacteria and fungi obtained from these plates. The exposures were made by Prof. Polunin with the facilities provided by the Royal Canadian Air Force, of which a general account has recently been published[3]. 'Vaselined' slides were exposed at the same time for rust spores, pollen grains, etc., and the results of this examination will be published separately.



The medium employed was designed to allow minimal growth, since it was expected that a considerable time would elapse between exposure and arrival at the laboratory. Czapek's solution agar was accordingly modified by omitting the sucrose and adding yeast extract. On June 23 the first set of plates (standard 10 cm. Petri dishes) was prepared, using 0·4 per cent yeast extract; these plates were exposed on August 12. As it was found that micro-organisms made good growth on this medium, it was deemed advisable to modify further the formula; accordingly the yeast extract was reduced to 0·1 per cent, and the agar content increased to 2·5 per cent. This second lot of medium was prepared on July 14 and was used in the remaining flights. In both cases the poured plates were left for one week at room temperatures and any that showed contamination were discarded. Details of the wrapping of the plates and the technique of exposure have already been described[3].

Following exposure, each plate was carefully rewrapped and packed, the complete stock of exposed and unexposed plates being kept together until the work was completed in early September. When the plates were returned to the laboratory on September 12 and 13 they were in excellent condition, all showing numerous small colonies of micro-organisms. Seven unexposed plates were carried throughout, and these were sterile when returned to the laboratory and remained so even after one month at room temperature.

The relatively slow air-speeds (see Table 1) made exposure by hand feasible, and the plates were held at a minimum of 20 cm. from the fuselage. Flight 1 was made in a Norseman aircraft which has a single propellor situated in front of the nose, so that these plates (1 to 11) may have been affected by the turbulence caused by the propellor. Flights II to IV were made in a twin-engined Canso flying boat in which the propellors are behind the co-pilot's seat from which the exposures were made; this permitted an unobstructed air stream to strike the plates (12 to 52).

The attempt was made to obtain exposures every 20 or 30 miles in a series of flights that would extend from temperate regions as far north as possible. Of the four flights (see accompanying map), one was near the extreme north-west of Canada and reached as far as the Arctic Ocean, while the remainder extended from Somerset Island to Edmonton, Alberta.

No attempt was made to obtain cultures from all of the colonies in any one plate, only those in which the colonies were well isolated and uncontaminated being used. Despite this precaution, many of the cultures proved to be contaminated, due possibly to several micro-organisms being present on a dust particle. In some cases, examination with a dissecting microscope revealed numerous microscopic bacterial colonies within the mycelium, and these colonies were readily transferred along with portions of the fungous hyphæ. It was believed that these tiny bacterial colonies (which were not included in the counts) either found the medium to be unfavourable or were inhibited by the fungi. Similarly, minute fungous colonies were also noted, although much less frequently: two such colonies when transferred to corn meal agar failed to grow.

The numbers of colonies of bacteria and fungi are given in Table 1 along with relevant data. It is evident that bacteria greatly outnumber fungi in most of the fifty-one plates exposed.

* One contaminant observed immediately following exposure.

** Mostly secondary colonies from large central one of sporulating *Penicillium*.

[1] Figures computed from time of exposure, speed of aircraft, and area of plate: it should be emphasized that they represent comparative rather than precise quantitative values.

Table 2 summarizes the subcultures that were made from representative bacterial colonies, in forty-five of the fifty-one plates. Transfers were not made from the other six plates because of bacterial spreaders, or because the colonies were covered with mould. All the subcultures were made on to nutrient agar slopes.

Wolf[4], in studies of the air over Nashville, Tenn., and Proctor and Parker[5] over Boston, found spore-forming bacteria comprising a high percentage of their colonies (37·7 and 52·2 per cent, respectively) and a low percentage of Gram-positive non-spore-forming rods. In the present investigation about 5·0 per cent were spore-formers and about 41 per cent were Gram-positive non-spore-forming rods. On the other hand, the percentages of *Micrococcus* and *Sarcina* were very close to those found by Wolf[4].

Table 2. Summary of preliminary study of bacterial cultures

Micrococcus	43
Sarcina	5
Achromobacter (probably)	8
Achromobacter or *Flavobacterium*	24
Gram-positive rods (unclassified)	20
Gram-positive rods morphologically like *Corynebacterium*	46
Spore-formers	8
No growth on transfer	21
Mixed cultures	13
Total	188

Table 3. Summary of preliminary identification of fungous cultures

Fungi Imperfecti	*Hormodendrum*	33
	Other Moniliales	20
	Phyllosticta	1
	Pestallozia	1
Ascomycetes	Yeasts	16
	Penicillium	15
	Leptosphæria	9
	Chætomium	1
Actinomycetales	*Streptomyces*	22
Other cultures	Non-sporulating	74
	Sclerotia-producing	2
	No growth on transfer	9
	Contaminated	4
	Total	207

Table 3 is a summary resulting from an examination of the fungi. Subcultures were made on corn meal agar. The lack of sporulation in many of the cultures is probably due to the presence of bacterial contaminants, and possibly to an unfavourable medium.

These cultures will be purified and grown on various media in order to induce sporulation, and a detailed report including identifications will be published later. The almost universal prevalence of *Homodendrum* in the air as indicated by many workers, including Wolf[4], Proctor and Parker[5], Meier and Lindbergh[1], is confirmed by its occurrence in 33 of the 207 cultures (15 per cent). Conspicuously absent among the sporulating cultures were *Aspergillus*, *Fusarium* and Phycomycetes.

On the basis of the colonies which developed in our plates, it would appear that bacterial cells greatly outnumber fungus spores in the arctic air. There appears to be no correlation between the number of colonies and geographical position, at least within the arctic and subarctic regions. However, in the region of Edmonton an increase of both bacterial and fungous floras was found which may possibly be related to areas of cultivation.

No explanation can be given for the high numbers of bacterial colonies encountered in the vicinity of Cambridge Bay on two successive days. The highest count was found on August 26 on plate 13 exposed some 50 miles north-east of Cambridge Bay, and high numbers were also found in plates 14, 15, 16 exposed still farther north. High counts were again obtained the following day on plates 28 to 30, plate 28 being exposed some 170 miles south-west of Cambridge Bay.

FORMATION OF HYDROGEN PEROXIDE IN WATER IRRADIATED WITH X- AND ALPHA-RAYS

By Dr. P. BONET-MAURY and M. LEFORT
Laboratoire Curie, Institut du Radium, Paris

IN spite of numerous studies, the primary action of ionizing radiations on water is not yet fully known. Knowledge of this action is important in relation to the radio-chemistry of dilute aqueous solutions and is required for the better understanding of the mechanism of the biological effect of these radiations, since water comprises about 80 per cent of living organisms. As the formation of hydrogen peroxide is regularly demonstrable in irradiated water[1], a systematic investigation of this phenomenon has been undertaken for radiations of very different ionic density, namely, 0·9 A. X-rays and polonium or radon α-rays.

Methods. The irradiation with X-rays and the titration of hydrogen peroxide were carried out by the methods already described[2]. In order to study the effect of dissolved oxygen, gases were eliminated from the water *in vacuo* by alternate evacuation and saturation with oxygen-free argon or nitrogen. Dissolved oxygen was titrated by a special method which permitted the assay of a 30-c.c. water sample, and the estimation of 0·2 mgm. of oxygen with an accuracy of 5 per cent. A control sample was assayed in an identical manner. Dissolved radon[3] or polonium was used as a source of α-radiation. Polonium was only employed under conditions which were such that the catalytic effect of this substance[4] on the decomposition of hydrogen peroxide was negligible.

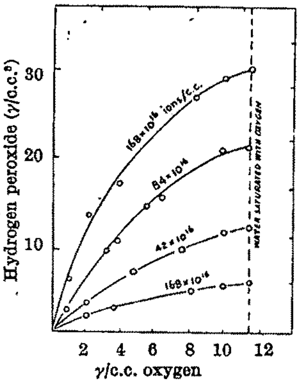

Fig. 1. Influence of dissolved oxygen. Doses of radiation: 168, 84, 42 and 16·8 × 10^{16} respectively

Effect of Dissolved Oxygen. (*a*) *X-rays.* For a given dose of radiation, the amount of hydrogen peroxide produced depends markedly upon the concentration of dissolved oxygen (Fig. 1). In water carefully freed from gas, it is no longer possible to detect any hydrogen peroxide, even after exposure to doses as high as $1{\cdot}7 \times 10^{18}$ pairs of ions/c.c., or more than 2,000,000 r. (surface dose).

(*b*) *α-rays.* The ionic yield, in the case of X-rays, suggests that the radon β-rays probably account for less than 5 per cent of the total effect of the α+β-radiation. We have verified this fact directly, using only the action of the β-radiation, α-rays being stopped by a vial of thin glass containing the radon and directly immersed in the titanium reagent. When water was exposed to the α-radiation from dissolved radon and its disintegration products, the following results were obtained. In water completely freed from gas and therefore containing no oxygen which could take part in the reaction, the ionic yield of hydrogen peroxide was found to be the same as in oxygen-saturated water. The same result was obtained when polonium α-radiation was used; but the experiments in this case were complicated by the catalytic effect of the radio-element, which tended to decompose the hydrogen peroxide produced. When initial radon concentrations of 1–3 mc./c.c. were used, the ionic yield was independent of the dose within the whole interval tested (Fig. 2). (The ionic yield is,

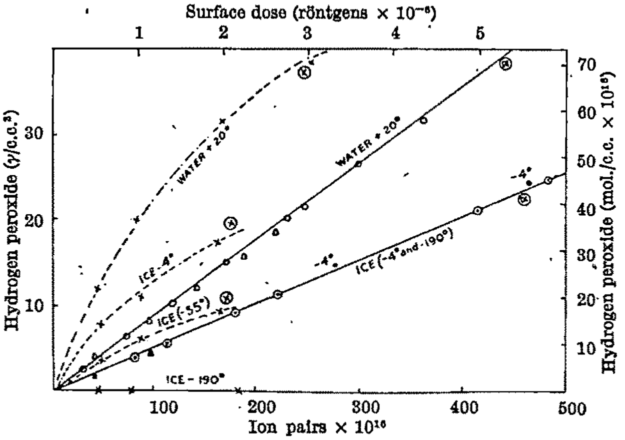

Fig. 2. The curves refer to water (+ 20°), ice (− 4°), water (+20°), ice (− 55°), ice (− 4° and − 190°) and ice (−190°)

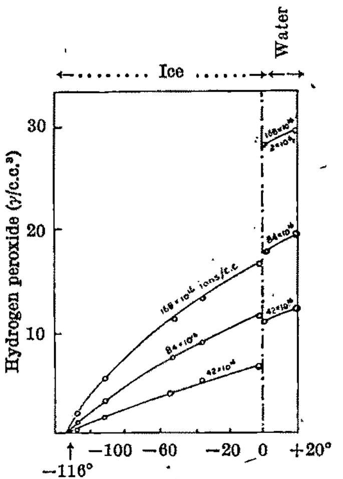

Fig. 3. Influence of temperature. The doses of radiation (reading from the top) are 1/68, 84 and 42 × 10^{16} ions/c.c. for ice; and similarly for water

of course, generally defined as the ratio of the number of molecules decomposed to that of ion pairs produced; this definition is not applicable to hydrogen peroxide formation, because the number of water molecules decomposed is not directly known.)

Temperature Effect. (*a*) *X-rays.* In oxygen-saturated water, the production of hydrogen peroxide decreases regularly with the temperature, a definite discontinuity marking the passage from water to ice (Fig. 3). Below −116°, it is no longer possible to detect any hydrogen peroxide, even when the dose is 2 × 10^6 r. (Fig. 3).

(*b*) *α-rays*. The temperature seems to be without influence on the production of hydrogen peroxide in water and ice by the α-radiation from dissolved radon. At the transition point from water to ice, a discontinuity similar to that of X-rays was observed (Fig. 1). Polonium α-rays give similar qualitative results, the catalytic effect of the radio-element being considerably decreased as the temperature is lowered.

Discussion. The experimental results show that hydrogen peroxide is formed according to different mechanisms for X- or α-rays, and that the linear ion density of the radiation affects the primary reactions concerned with the decomposition of the water.

These data are perfectly concordant with the hypothesis suggested by some British workers[5] for the interpretation of the differences between the radiobiological effects of X-rays and α-rays. According to those conceptions, the principal result of the ionization of water is the production along the track of the ionizing particle of hydrogen atoms and hydroxyl radicals (Weiss), the spatial distribution of which corresponds with that of primary ion pairs (Lea and Gray).

For X-rays, the distribution is such that the hydrogen atoms remain near the hydroxyl groups, and, in the absence of oxygen, their recombination to give water is the most likely reaction. When dissolved oxygen is present, the reaction

$$2H + O_2 = H_2O_2 \qquad (1)$$

becomes possible and produces hydrogen peroxide in amounts which increase with the oxygen concentration and the temperature.

Along the trajectory of an α-particle, the hydroxyl groups remain concentrated in the centre of the ionization column and are at first isolated from the hydrogen atoms which form a surrounding sheath. The reaction

$$OH + OH = H_2O_2 \qquad (2)$$

is the most likely, and it produces hydrogen peroxide even in the absence of dissolved oxygen; the reaction seems to be independent of the temperature. The constant ionic yield for α-rays indicates that, when oxygen is present, the amount of hydrogen peroxide produced according to reaction (1) is negligible compared with that produced according to reaction (2).

From these results, it appears that hydrogen peroxide plays an important part in the mechanism of the biological effect of radiations, since its formation seems to be one of the radiochemical primary reactions produced in aqueous media exposed to ionizing radiations.

The remarkable constancy of the ionic yield with α-rays shows that the photocolorimetric method is particularly convenient for the radiochemical dosage of dense ionizing radiations such as recoil protons or neutrons.

NATIONAL INSTITUTE OF INDUSTRIAL PSYCHOLOGY

THE annual conference of the National Institute of Industrial Psychology was held in Buxton during April 9–12, and a report has now been issued ("Psychology at Work", 1, No. 3; July 1948). Welcoming the delegates to the Conference, the chairman of the Institute, General Sir Ronald Forbes Adam, stated that everywhere in industry management is facing the fact that output must be raised if Britain is to retain its standard of life; but the re-equipping of industry is going to take a long time and some means must be found of achieving the goal more quickly. It has now been generally realized that this increase in output can be achieved if greater attention is paid to human relationships; but there has been too little research into this problem. The aim of the Conference was to discuss some of the fundamental issues of human relationships, and its purpose can be summed up in three questions: (1) How much knowledge on the subject exists? (2) Is the knowledge readily available and is it being utilized? (3) What research can be undertaken?

The first session of the Conference was grouped under the heading "The Man and the Job" and, in the first address, Mr. Robert Watson, chief personnel officer to the Philips group of electrical companies, discussed the selection and allocation of workers. In a recent attempt to check selection and placement practices in industry, Mr. Watson and his colleagues sent out a questionnaire to about two hundred firms in many industries. Replies were obtained from sixty-three firms, including a high proportion of the acknowledged better employers, employing altogether about 300,000 persons. Of the sixty-three firms, four employed full-time psychologists; fifty-two did not give special training to employment interviewers and fifty-three companies did not use job specifications. Forty-eight companies did not give dexterity tests to hourly-paid operators, and fifty-three companies did not give intelligence tests to hourly-paid operators. From this and other data supplied by Mr. Watson it seems reasonably certain that few companies are taking advantage of the latest psychological developments in the use of selection methods. If companies could be persuaded to make use of modern employment practices it would do much to reduce the heavy burden of labour turn-over costs which help to inflate the price of the finished article. While it is not easy to obtain the costs of labour turn-over in any one industry, figures obtained from a firm employing 4,500 females and 3,380 males on mass production work showed that there is a labour turn-over in 1947 of 56 per cent of the total female hourly-paid workers and 38 per cent of the male workers; of those who left the firm during the year, 67 per cent of the women and 72 per cent of the men were in their first year of service.

In a paper on training and working methods, Colonel B. Ungerson, chief psychologist, Directorate of Manpower Planning at the War Office, described the methods which give best results in providing training for unskilled and semi-skilled jobs. Instead of the existing method of placing a newcomer with an experienced operator and telling him to get on with the job, Colonel Ungerson suggested that the efficiency of a department would be considerably improved if newcomers were given definite training under competent instructors. This training should include the presentation of knowledge which would include the most suitable tools for the job, when they were satisfactory for use, what raw materials were used for which jobs and so on. This should be supplemented by as many practical aids as possible, including diagrams, models (or the real thing if possible) and a museum of faults; these should apply both to raw materials and finished products. The problem of developing skill is to ensure a repetition of good movements until they become habitual; this should be based upon movement study and is not necessarily complex. Colonel Ungerson then gave some examples of how skill could be developed in various unskilled and semi-skilled jobs.

Following the papers by Mr. Watson and Colonel Ungerson, the Conference divided into eight discussion groups which reported their findings to the Conference at the end of the first day. Summing up the findings of the groups, the chairman, Lord Piercy, said that we are faced with the problem of more production with a given labour force. We can only cut our costs by three means: education, application of what is known, and research. In the field of the education of management we are not yet getting the full benefit out of good practice and, although there will be 'sales resistance' all the way down the management chain, we must get the practice of good firms accepted by others. In the application of particular items of information he was impressed by the stress which has been laid on training as opposed to selection. Training undoubtedly is the key to prompt results, but the individual as a whole should be considered, and here selection is important. On the subject of research it is necessary to pool all our ideas. The problem of the use of individuals of low mentality might profitably be pursued further, and it is pleasing to report that over the last year the Government has come to realize the importance of this work; Panel 3 of the Committee on Industrial Productivity was specially charged with the consideration of the human factors affecting production.

The second session was grouped under the general heading, "The Firm as a Working Unit". Mr. Graham Satow, director of training, Stewarts and Lloyds, Ltd., in a paper on the supervisory grades, traced the development of a changed outlook among workpeople and into this background fitted the position of the foreman and his problems. The same difficulties seem to be encountered on both sides of the Atlantic, and he suggested that the two aims should be to strengthen the foreman's status in the firm and to develop a changed pattern of leadership in the supervisory grades. Mr. Satow then made many practical suggestions as to the methods in which these aims could be realized.

Probably the highlight of the Conference, however, was the paper by Mr. W. L. Mather, director of Mather and Platt, Ltd., on communication within the firm. Borrowing from his experience at the Army Staff College, Mr. Mather gave a practical demonstration of the way in which two-way communication could take place within the firm. Two boards were placed in front of the audience, one of which was marked "Management" and the other "Workers". Between these two there was a gap which, he said, represented the gap between management and workers about which so much was being talked at the present time. The problem is to bridge the gap. Very useful bridges across the gap are provided by personnel departments, works committees, joint production consultative and advisory committees, general committees, training, notice boards, broadsheets, magazines, suggestions schemes, lectures and verbal instructions. These bridges can easily be broken, however, and with a compelling dramatic presentation in which he was helped by a typical British workman, Mr. Mather showed how the only real way of providing communication in any firm is by personal contact.

After further discussion, the second session was summed up by Sir Godfrey Ince, permanent secretary to the Ministry of Labour and National Service, who stated that he was glad that the Conference emphasized the problem caused by the changed outlook of the worker. To find the right relationships between the man and the job involves using the right methods of selection, training and allocation, and use can be made of the Ministry of Labour's experience both with the Juvenile Employment Service and in providing supervisory training through the Training within Industry Scheme.

The final address to the Conference was given by Mr. Austin Albu, deputy director, British Institute of Management, who said that it is the variation between firms which has to be considered when approaching our industrial problems. Some British firms have employed methods which equal those of any other country, and the need is to bring all firms as near as possible to this standard. This can be done, first, by selling ideas to management; secondly, by breaking down the resistance of trade unions and abolishing restrictive practices generally; and thirdly, by training first-line supervisors. The Conference has profitably discussed ways in which these things can be done, and it is hoped that the British Institute of Management will soon be able to be of direct service to industry. T. H. HAWKINS

FORTHCOMING EVENT

Thursday, September 9

University of Manchester (in the Physical Laboratories, Manchester).—Discussion on "Meteors" (to be opened by Dr. F. L. Whipple).

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturer (temporary), and a Demonstrator, in the Department of Botany—The Registrar, The University, Leeds 2 (September 10).

Demonstrator in Chemistry and Biochemistry with a special interest in Physical Chemistry—The Dean of the Medical College, St. Bartholomew's Hospital, West Smithfield, London, E.C.1 (September 11).

Assistant Lecturers (3) in the Department of Civil Engineering, to assist in the subjects of Theory of Structures and Fluid Mechanics—The Professor of Civil Engineering, City and Guilds College, South Kensington, London, S.W.7 (September 13).

Lecturer (woman) in Geography, and an Assistant Librarian (man or woman)—The Warden, Goldsmiths' College, New Cross, London, S.E.14 (September 14).

Technical Assistant (man or woman, Grade B) for experimental research work in the Zoology Department—The Registrar, University College of North Wales, Bangor (September 15).

Lecturer in Experimental Pharmacology—The Secretary, The University, Aberdeen (September 15).

Lecturer in Botany at Farouk I University, Alexandria—The Director, Egyptian Education Bureau, 4 Chesterfield Gardens, London, W.1 (September 15).

Research Officers (4), Assistant Research Officers (5), and Research Assistants (3), in the Board of Trade—The Secretary, Civil Service Commission, Burlington Gardens, London, W.1, quoting No. 2267 (September 16).

Research Assistant (with Honours Degree in Botany and, if possible, some practical experience in Horticulture) to work on Strawberry Breeding—The Secretary, School of Agriculture, Cambridge (September 25).

Assistant Lecturers (2) in Anatomy—The Secretary, University College, Gower Street, London, W.C.1 (September 25).

Deputy Curator at the Horniman Museum, London Road, London, S.E.23—The Education Officer (Estab/2), County Hall, Westminster Bridge, London, S.E.1 (September 30).

Controller of Telecommunications, Civil Aviation Branch, Air Department, Wellington—The Office of the High Commissioner for New Zealand, 415 Strand, London, W.C.2 (September 30).

Lecturer in Electrical Engineering at the University of the Witwatersrand, Johannesburg—The Secretary, Universities Bureau of the British Empire, 32 Woburn Square, London, W.C.1 (October 1).

Technician to take charge of Medical Unit Laboratory—The Secretary, St. Mary's Hospital Medical School, Praed Street, London W.2 (October 1).

Lecturer in General Bacteriology, and a Research Assistant and Demonstrator (temporary) in Botany—The Registrar, University College of South Wales, Cathays Park, Cardiff (October 2).

Chair of Experimental Physics, and an Assistant Professor of Experimental Physics, in the University of Geneva—Le Conseiller d'Etat charge du Departement de l'Instruction Publique, 6 rue de l'Hotel-de-Ville, Geneva, Switzerland (October 15).

Readership in Physiology at St. Bartholomew's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (October 18).

Studentships (4) at a British (or, exceptionally, foreign) research institute in preparation for Fisheries Research in the Colonial Empire—The Under-Secretary of State, Colonial Office, Research Department, Sanctuary Buildings, Great Smith Street, London, S.W.1 (October 31).

Senior Lecturer or Lecturer in Chemistry at Canterbury University College, Christchurch, New Zealand—The Secretary, Universities Bureau of the British Empire, 32 Woburn Square, London, W.C.1 (November 1).

Readership in Physics (in the field of Metal Physics) at University College—The Academic Registrar, University of London, Senate House, London, W.C.1 (November 4).

Lecturers in Physics, a Lecturer in the Department of Mathematics, and a Senior Assistant in the School of Chemistry—The Registrar, College of Technology and Commerce, The Newarke, Leicester.

Inspector of Mines (to act also as Inspector of Quarries and Explosives and Technical Adviser to the Mining Board) in the Department of Lands, Mines and Surveys, Fiji—The Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Botanists (to undertake the improvement of economic plants by selection and breeding, and to investigate and control plant disease) in Nigeria—The Director of Recruitment, Colonial Service, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Senior Technicians (2) in the National Blood Transfusion Laboratory, Cardiff—The Regional Blood Transfusion Officer, 19 Newport Road, Cardiff.

Senior Laboratory Steward (Chemistry and Biology)—The Bursar, Merchant Taylor's School, Sandy Lodge, Northwood, Middx.

Laboratory Assistant—The Headmistress, Godolphin and Latymer School, Hammersmith, London, W.6.

Laboratory Assistant in the Chemical Laboratories—The Principal, County Technical College, Stoke Park, Guildford.

Laboratory Technician—The House Governor, Skin Hospital, John Bright Street, Birmingham 1.

Lecturer in Chemistry to Intermediate B.Sc. stage—The Principal, Medway Technical College, Gardiner Street, Gillingham, Kent.

Lecturer in the Natural Philosophy Department—The Secretary, Royal Technical College, Glasgow.

Assistant Lecturer in Agriculture, and a Demonstrator in Chemistry—The Registrar, The University, Nottingham.

Principal Medical Officer/Research (bacteriologist with good experience of original research), a Principal Scientific Officer (bacteriologist with good experience of original research), a Principal Scientific Officer (biochemist with first- or second-class honours degree and good experience in original research), and Medical Officers/Research (bacteriologists or experimental pathologists with experience of original research), in the Microbiological Research Department of the Ministry of Supply—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2274.

Biochemist to undertake establishment and direction of biochemistry research and development laboratory in Serum Institute, Naples—The Secretary, Wright-Fleming Institute of Microbiology, St. Mary's Hospital, Paddington, London, W.2.

Engineer specializing in drilling and blasting operations (Ref. TT.76), an Engineer specializing in shaft sinking and tunnelling operations (Ref. TT.77), and an Engineer specializing in mechanical stowage (Ref. TT.78), in the Production Department in London—The National Coal Board, Establishments (General) Branch, Hobart House, Grosvenor Place, London, S.W.1, quoting the relevant Ref. No.

Agricultural Chemist in the Agricultural Department of the Government of Kenya—The Director of Recruitment, Colonial Service, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Senior Meteorological Officer for the Government of Falkland Islands Dependencies Survey for service in the Antarctic—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.N.21628/3E.

BALANCE BETWEEN THE PURSUIT AND APPLICATION OF SCIENCE

IN title, and, to some extent, in content, Sir Henry Tizard's presidential address to the British Association (see p. 392) recalls that of General Smuts to the centenary meeting in London, though in form the outlook of the present chief scientific adviser of the Government resembles rather that of the engineer, as it was put by Sir Alfred Ewing. All three addresses glance at that Victorian era, the ideas and beliefs of which must have been made more familiar to many of Sir Henry's audience by the series of talks broadcast in the B.B.C. 'third programme' this spring. Already, however, the scientific world picture which General Smuts outlined has changed considerably, as indeed he indicated it would do ; and although Sir Henry Tizard did not pursue the philosophical theme of the centenary address to the British Association, it is clear that one or two of its points were in his own mind.

Science now, as he pointed out, stands higher in the public esteem than it has ever done in Britain. The public controversy between science and religion has died down, and the recent report of the Lambeth Conference provides evidence of a changed attitude and outlook on the part of the churches assembled there that would have seemed startling indeed to the Victorians, even to those with scientific interests who gathered in Brighton for the meeting of the British Association in 1872. Indeed, the frankness, clarity and logic of that report may well astonish many men of science who have not yet realized how truly science and religion stand on the same side in the defence of freedom and the moral, spiritual and cultural values of civilization.

At these values Sir Henry, however, gave no more than a passing glance. Instead, we have been given a world picture in which the central and dominating figure is man and his activities. The world, he suggests, is passing from one state of unstable equilibrium to another, and will be unstable for many years to come. We can at least strive to balance it so that the chance of a major catastrophe is made as small as possible, and Sir Henry holds that science has much to contribute towards this aim. We should ask ourselves whether we are not claiming too much for science in some directions, and doing too little in others ; and, in words that recall those of General Smuts and also those of Sir Alfred Ewing, he suggests that we should consider in fact whether the great forces of science, on the proper exercise of which all social progress depends, are in balance.

The balance to which Sir Henry addresses himself more particularly is not that between ethical and material values, between science, art and religion, but between the pursuit and the application of science. To read his presidential address is to realize the extent to which his master mind is influencing the work of the Advisory Council on Scientific Policy as revealed in its first annual report. Some of his remarks may fail to reach all the industrialists or professors or directors of research for whom they are plainly intended ; but Sir Henry's position justifies the confidence that he will not fail to make those views known in any quarter that may be desired.

This part of the address is essentially a sermon on economic recovery. Sir Henry suggests that one of the lessons of the last two generations is that the decline in the prosperity of some branches of industry is due to their tendency to go on doing what manufacturers know they can do successfully rather than to launch out in new directions. Sir James Morton, for example, used to contend strongly that this was the real reason for the depression in the cotton industry in the nineteen-twenties; Sir Henry himself suggests that this rather than the neglect of science was the real reason for the development of synthetic dyes and fine chemicals in Germany rather than in Great Britain.

But after a tribute to the quality of the reserve of scientific ability in Britain as revealed in both the world wars, and a warning as to the importance of maintaining the quality of academic research, Sir Henry puts in a timely protest against excessive drift of scientific man-power to the universities. He wonders whether we are not already over-populating the research departments of universities. Industrialists, who are looking patiently to the universities to provide the recruits to their research and production departments which they are at present unable to find may share that wonder. They may equally believe that university research departments are not the only over-populated departments, and the subsequent reports of the Advisory Council on Scientific Policy will certainly be scanned for evidence that the chairman is making his own views on the distribution of scientific man-power effectively prevail.

There need be no fear that whatever action the Advisory Council may inspire will impair the high standard of teaching in the universities or the schools of Britain, or impede the expansion of education in the higher branches of technology. We have become a scientific nation, but there is still too slight an understanding of the nature and the limitations of research; and a main theme of Sir Henry's address is that which recurred in the annual reports of the Department of Scientific and Industrial Research before the War. Sir Henry contends that industrial prosperity will depend more and more on the continuous application of science to industrial practice. Without disparaging new knowledge or research, he points out that the first requirement at the present time is the application of existing knowledge.

The prime object of industrial research is to do something that has never been done before, or to do things better than they have ever been done before. Furthermore, all social progress, such as the spread of education, promotion of health, and opportunities for leisure and healthy recreation, must depend on the power of science and technology to increase the productivity of industry. The productivity of labour in Britain is far lower than it could be if the results of past research were more resolutely and continuously applied. Sir Henry instances building, the coal industry and textiles, and suggests that the real reason for the higher productivity of such countries as Sweden and Switzerland is not in superiority of natural resources or in the quality or quantity of scientific and industrial research, but in their higher average standard of technology and in the greater proportion of men of high scientific education in executive control of industry.

It is not the general expansion of research in Great Britain that is of the first importance for the restoration of its industrial health, and certainly not the expansion of Government research remote from the everyday problems of industry. In Sir Henry's view the immediate task should be to apply what is already known. That view will be welcomed by many for its implications in regard to the distribution of man-power; but before considering two of these implications in particular, it is interesting to note that without using the stock term 'operational research', Sir Henry commends as one practical means of assisting the application of existing knowledge the technique used in progressive industry in technical service long before the War and developed with such remarkable success by the fighting services in the attack on problems of war.

The concluding observation in this connexion brings out the really vital factor in the utilization of science to-day. In the technique to which Sir Henry refers, far more attention is given to the study of man in relation to the machine he has to operate than in any branch of industry. Those industries which have gone furthest in that direction are precisely those in which human troubles, if not entirely absent, are most inconspicuous. In them, therefore, under such conditions, is there the best prospect of achieving that special object which all industrial research should have, namely, of reducing the labour required to supply the material needs and wants of men.

The central problem in the utilization of scientific knowledge in our economic recovery is thus that of man: of the wise use of man-power, of distribution or redistribution, and of securing the willing and intelligent co-operation essential for the full use of the new powers which applied science has given us. The importance of the work of the committee on human factors concerned in industrial productivity, of which Sir George Schuster is chairman, could scarcely have been better emphasized. Although Sir Henry's direct responsibilities in that field have now ceased, it seems certain that the work initiated by the Committee on Research and Productivity will continue to be watched by him with interest and firm support.

On the material plane, subject to the qualifications already indicated, Sir Henry takes a hopeful view of the future. He is reassuring on the question of food supply, but points out that it is on the development of the biological sciences that the peace and prosperity of the world depend. He considers that, so far as Great Britain is concerned, we must plan our economy on the assumption that food will be both scarce and dear for many years to come; and the answer to the question how long depends less on the ability than on the will of man.

"Science", said General Smuts at the centenary meeting of the British Association, "has come to represent the growing point of the human advance. It stands for the new forces which are re-shaping this world of ours. It faces the future with a bold and confident spirit. It has an invincible faith in truth at all costs ; and in that faith it is embarked on the endless adventure which carries the future of the human race."

In seventeen years we have lost something of that confidence in science, and in spite of the respect to which Sir Henry Tizard rightly referred, there have been new doubts as to the sufficiency of science. Science alone, it is widely held, is not enough ; and in the world of science there are many who believe with the Lambeth Conference that technical discovery must be brought into line with ethical direction. Sir Henry Tizard recognizes that we live in difficult times, but it is from Whitehead rather than Smuts that he draws his inspiration when he urges that it is a time for adventure, for taking calculated risks.

Sir Henry's contacts with the universities and with industry have convinced him that the spirit of adventure in science is as lively as ever it was. He looks forward to the future in the belief that by finding the right way to combine originality in science with enterprise and speed in its application, the nation can climb from the depths of bankruptcy to new and unsurpassed heights of prosperity and influence. Some successor in the presidential chair may or may not have occasion to refer to the great influence of the work of a few young men, who are now unknown to the public. Sir Henry's audience will look forward to that future with the greater confidence, because one whose foresight did so much to prepare our scientific resources for war is in the position to influence as potently their ordering for the tasks of economic recovery and of peace.

PLANT COMMUNITIES

The Study of Plant Communities

An Introduction to Plant Ecology. By Prof. Henry J. Oosting. Pp. 389. (San Francisco : W. H. Freeman and Co., 1948.) 4.50 dollars.

SINCE plant ecology first started, as a distinct division of study within the major science of botany, with the publication of Warming's "Plantesamfund" in 1895 (first German edition in 1896 and an English edition, "Oecology of Plants", Oxford, 1909), it has owed much of its rapid growth to American workers. In particular, the concept of succession was clarified and systematized, if not conceived, in the United States, and its development has been stimulated and largely directed by the researches, terminology and theories of American ecologists. It is therefore to be expected that text-books of ecology intended primarily for American students should record progress periodically. Such works naturally have both peculiar value and particular limitations for students in other countries. They direct attention to points of view and literature which might otherwise be overlooked and to examples which might remain unknown. On the other hand, it is not always easy to evaluate the conclusions reached because of unfamiliarity with both the flora involved and the field conditions.

The book under notice covers fairly adequately the subject of plant communities or synecology as an introduction to a part of plant ecology. After a preliminary discussion on the subject-matter of ecology there are five parts, with a total of eleven chapters, dealing with the plant community, factors controlling the community (the environment), community dynamics and practical considerations. A useful distinction is made early on, and emphasized several times later, between a concrete or specific example of a community and the abstract community as a synthetic idea derived from a study of several or many concrete examples or stands. Terminology is introduced gradually in the text and nowhere overwhelms the reader. Divergent points of view are judiciously treated. For example, the description and classification of communities, as developed especially by European writers, is contrasted with the view of vegetation as changing by development from origin to climax. Yet "each method has its place and usefulness. In fact each has profited from the other, but since the dynamic point of view has the broadest usefulness in both pure and applied ecology, it will be emphasized here." Importance is rightly given to the need for quantitative data in vegetational analysis. Refinements of the quadrat method, density, frequency, cover and space are considered. Qualitative characters, including sociability, dispersion, vitality, stratification, and periodicity, and "synthetic characteristics", such as presence, constancy, and fidelity, are discussed.

Considerable space is devoted to describing the factors controlling the community and the methods of measuring them and their influence on vegetation. Climatic, physiographic (mainly soil), and biological factors are dealt with in four chapters. The treatment accorded is on the whole adequate and up to date so far as American research is concerned, but would have been improved by the inclusion of European research, especially on 'biological' (or better, 'biotic') factors. The account of plant competition, for example, could have been much improved by reference to published researches on British vegetation.

A concise account of plant succession is followed by a very useful chapter on the distribution of climax communities in North America. This summary of the principal vegetational features of the continent is likely to be welcomed by many students of plant geography. The chapter on shifts of climaxes with time suffers from having only very brief references to work done outside North America, and from over-condensation, especially of the subject of pollen analysis.

The final chapter, on applied ecology, is to be commended as linking up scientific investigations with the satisfaction of human needs in the practices of forestry, agriculture, conservation, water supply, and what is termed 'landscaping'. The extent of this chapter could have been enlarged with advantage.

The book is illustrated with 190 figures. These are mostly well-chosen and fairly well-reproduced photographs, but include some outline drawings. There are also a number of tabulations. Besides "General References" at the ends of chapters there is a list of 276 "References Listed". The vast majority of the references are to American publications. It is, for example, surprising to find only two or three references to papers in the *Journal of Ecology*, which was not only the pioneer of ecological periodical literature but has always been and is still in the first rank. There is an adequate index.

A general criticism, which has already been indicated, is the relative neglect of non-American investigations. One would naturally expect emphasis to be given to American work and examples to be chosen largely from North American vegetation; but more consideration of various methods of study, both of vegetation itself and of the factors of the environment, which have been developed in Europe and elsewhere would have added greatly to the value of the first half of the book. It is also unfortunate that, in common with many other text-books of ecology, the dependence of good ecological work on the correct determination of the organisms composing the communities studied is not stressed.

W. B. TURRILL

LOCAL GENII OF BRITISH FOLK-BELIEF

The Minor Traditions of British Mythology

By Lewis Spence. Pp. 176. (London: Rider and Co., 1948.) 16*s*. net.

THIS volume is an attempt to present in concise and summarized form some of the lesser facts and circumstances of British mythology which, although dealt with in some detail by writers in the more specialized journals devoted to folk-lore, have not yet received adequate attention in more popular books. It has been Mr. Spence's object to collect together many of the more local British traditions as they are expressed in legend and folk-tale, and show how the rivers, mountains, lakes and wells are peopled by a motley collection of goblins and demons, giants and monsters, vegetation spirits and supernatural birds. To the stories concerning these monsters the author has added the legendary material which has collected in such quantity around the standing stones of Britain and the dolmens and menhirs which can be treated with them.

It follows from the plan designed by the author that a good deal of the material with which he deals is concerned with those local genii and solitary spirits who rarely seem to have attained more than a local distinction, but who, in many cases, can be linked up with more prominent mythological figures.

Having discussed the spirits which are connected with British rivers, lakes and wells, Mr. Spence proceeds to give an interesting account of mermaids and seal-folk, and then goes on to discuss the giants and ogres of England. He is of the opinion that many of these gigantic divinities were the original deities of this island; and from the passages he quotes it would seem that at one time Britain must have been the home of many giants, some of whom were guilty of exceedingly unpleasant habits. Passing in review the giants of Scotland, Ireland and Wales, Mr. Spence then continues his narrative by an account of British goblins and demons, a chapter which could, I think, have been considerably enlarged with great advantage to the reader. The author points out that what he calls the demonology of Britain is the equal of any to be found in Europe, and although it does not present the number of fantastic varieties to be found in Germany, the type is broader, owing perhaps to the great admixture of stocks which makes up the British population. How far this is true it would be difficult to determine without a much more detailed examination of the legendary figures and their possible sources than has been attempted here. What is clear is that British goblins have appeared in numberless forms, many of which were described by Scot in his famous sixteenth-century book on witchcraft. Here will be found a catalogue of sprites listed under such names as bull-beggers, sylens, pans, kit with the cansticke, calcars, the hell-waine, the puckle "and such other bugs". Mr. Spence rightly points out that few of the types listed by Scot are actually of British provenance, while others are of the fairy class to which, in the present volume, the author has not turned his attention.

In the discussion of these curious demonic figures some of them are compared with so-called poltergeists, inasmuch as a few were noted for their tricks and troublesome antics. Thus the Hedley kow seems to have been of this type, for it would disguise itself as a truss of straw, and when someone tried to pick it up it would become so heavy that it would have to be laid down to let the bearer have a few minutes rest. Thereupon it would suddenly come to life and shuffle away with a peal of laughter.

It would be of interest to discover whether legends of this sort can be in any way linked up with the many accounts of poltergeist activity to be found in Great Britain. In the present volume, however, Mr. Spence has confined himself to a bald statement of the facts, and the reader is often left with a desire to know more just when his attention is directed to a fresh case. Indeed, the author might have been wiser had he not attempted to deal with so much material in so small a space. In its present form the book is little more than a very convenient and useful summary of the subject; but it would have been much improved if the dates of publication had been added to the material listed under the references, and the index much enlarged so as to include more of the proper names, and not only a certain number of them based on a method of selection the principle of which does not seem to be at all clear.

E. J. DINGWALL

THE GRADUATE IN INDUSTRY

The Graduate in Industry

By Dr. Percy Dunsheath. Pp. x + 276. (London: Hutchinson's Scientific and Technical Publications, n.d.) 10*s*. 6*d*. net.

THIS book is a thoroughly competent piece of workmanship which to some extent breaks new ground in that, unlike most 'careers' books, it indicates the trend of numerous occupations for university-trained men and women in industry and attempts to demonstrate the opportunities for service to the community which lie therein. In this his first objective, Dr. Dunsheath sets out deliberately to overcome some of the prejudices against entering industry which, according to Sir Lawrence Bragg and others, are sometimes manifest among students. While thus endeavouring to satisfy the ideals which often influence such students, Dr. Dunsheath remains essentially factual and has assembled a considerable amount of information not otherwise accessible in one volume, which should make his book of real value to the university appointments boards and to the higher appointments officers of the Ministry of Labour and National Service.

In his preface, however, Dr. Dunsheath indicates a second objective. He attempts to show both the need for a change of approach in university teaching for students destined for a life in industry, and that the new conditions of the present day may be adequately matched to the tradition of the university as a place where young people find a philosophy of life which remains with them to guide and strengthen them throughout the conflicts of life which lie ahead. Here Dr. Dunsheath has much to say that is stimulating and sometimes provocative, but he writes with insight as well as with a deep sympathy with the social aspirations that so often colour the ideals of students which will commend his book to them, no less than to those responsible for determining the trend and content of university teaching.

Dr. Dunsheath's book from the first point of view gives a fair indication of the structure on which the attempt to obtain quantitative estimates of the future demand for graduates should be based. Here his book is as important to the industrialist as to the appointments boards which attempt to prepare those estimates. Some chapters, indeed, are almost specifically addressed to the industrialist: if there are graduates prejudiced against entering industry there are also industrialists prejudiced against employing graduates in some at least of the fields which Dr. Dunsheath indicates. He gives some attention to the question of the man of science as administrator, and not only here but also in other places he emphasizes the importance of the student taking full advantage of the opportunities which a university offers to broaden his mind and outlook and enlarge his contacts with men and women. All the weight of his experience is thrown against the narrow bookish conception of education, as it is against premature or excessive specialization.

As might be expected in a book of this size, some parts of the wide field are surveyed rather sketchily, and Dr. Dunsheath would be the first to admit that he initiates rather than exhausts either discussion or description. Nevertheless, he has given a fairly clear statement of what is involved in the present discussion on the expansion of the universities, and his book should not be without value to those also who are endeavouring to see that a reasonable balance is achieved between the numbers of university-trained men and women who enter industry and those entering the universities and the public services. For its price, the printing and production might well have been better; its usefulness would be increased if it could be issued in another edition at half the price.

R. BRIGHTMAN

SEA WAVES AND SURF

Wind Waves at Sea, Breakers and Surf

By Henry B. Bigelow and W. T. Edmondson. (United States Navy Department: Hydrographic Office: H.O. Pub. No. 602.) Pp. xii + 177 + 24 plates. (Washington, D.C.: Hydrographic Office and Government Printing Office, 1947.) 2.80 dollars.

SEA WAVES are as unruly as ever; but their characteristics are becoming more predictable as knowledge accumulates. The pioneer work of Arago and Stevenson was energetically extended by the American army engineer Gaillard, whose book on "Wave Action" published in 1904 has recently been reprinted. The aim of theory has always been to extract from the reality simpler ideas that are comprehensible; that real sea waves are complicated is sufficiently evident from the stereophotographs and contour diagrams prepared in 1939 by Schumacher. The first mathematical guess at the nature of a sea wave was made by Gerstner in 1802, and the later theories, most notably those of Stokes and Rayleigh, have provided a sound basis for the work of the physicist and engineer.

The appearance, therefore, of a book by Henry B. Bigelow and W. T. Edmondson is particularly welcome because of the extensive work on waves that has been done since 1940. It is described in the preface as a popular book; but the reader may take notice that it contains too many facts to be easy reading for the landsman. It aims at being a simple comprehensive account of wind waves written for the seafaring man. For this reason it is not a text-book, and the authors present only the general findings of theory supported by numerous practical illustrations taken mainly from the seaboards of North America. This practical bias is very desirable in a science which has such practical applications. The European reader may find difficulty in appreciating the practical examples and applying them to his home waters, unless he is provided with a good atlas of the American lakes and seaboards. The book is illustrated by 57 photographs and diagrams and contains 37 numerical tables with a sufficient number of selected references.

A notable feature of the book is an atlas of the frequency of occurrence of high seas and low seas and of high swells and low swells in all the major oceans during summer and winter. This atlas is one result of the military demands of the Second World War; it may prove to be of value to commerce, since such information is needed in the construction of new harbours and other engineering ventures that are exposed to the sea, as, for example, certain new oilfields. This atlas is the only one available as yet to the public.

The first four chapters describe the character of waves at sea, their growth under wind and their propagation away from the storm as swell. The last three chapters describe how waves change their behaviour when approaching the coast, due to shoaling water, to refraction around islands or headlands or to the effect of tidal streams, and describe the different types of surf which form on various beaches. The complicated effects are rationalized in a pleasing way, and these chapters deserve the attention of all maritime engineers. Though the discussion of theory is avoided, the numerous practical observations will suggest useful lines of work to the specialist. Is the grouping of waves, for example, as fortuitous as it might seem, for if fifty or more successive waves are observed by a ship, could not the next one be predicted with fair certainty? When a moderate swell is partly beaten down by an opposing wind, in what form does it emerge? Is its wavelength increased or diminished or does it merely show a reduced height?

As a correction of fact it may be pointed out that in 1911 Rayleigh deduced that waves would show a small decrease in height as they first approached shallow water, so this is not a recent discovery.

The authors give no space to the description of modern wave-measuring instruments or to techniques such as frequency analysis which are advancing the science. These subjects would find a place in a specialist's text-book, and it is to be hoped that the authors will compile one, since the present book meets its own purpose so well.

N. F. BARBER

FREE RADICALS IN CHEMISTRY

The Chemistry of Free Radicals

By Dr. W. A. Waters. Second edition. Pp. viii + 296. (Oxford: Clarendon Press; London: Oxford University Press, 1948.) 20*s.* net.

DURING recent years it has become increasingly evident that free atoms and radicals, chemically very reactive but physically quite stable, play an important part as intermediates in chemical reactions. Thus the equation of a chemical reaction, as usually formulated, is very often merely the sum of many separate equations involving their short-lived substances, and a knowledge of their properties and reactivity is necessary if we are to understand the mechanism of the reaction as a whole. Consequently there has arisen in the last two decades a new kind of chemistry, no longer bound by the usual valency rules—the chemistry of free radicals. Dr. Waters' book surveys in a general way the whole of this rapidly growing subject.

The second edition, which has just been published, is identical in subject-matter with the first, published two years ago, but several minor alterations have been made and references to work published in 1947 are included. The approach to the subject is that of an organic chemist interested in understanding better the well-known reactions of organic synthesis. Physical methods of investigation, such as spectroscopy and mass spectroscopy and the results of theoretical chemists on free radical structure, are therefore omitted, although there is a fairly detailed chapter on the use of magnetic properties of free radicals as a means of diagnosis. After a general and historical introduction on the methods of production and detection, there are chapters on resonance-stabilized radicals of the triphenylmethyl type, the gas reactions of free atoms and the reactions of alkyl and aryl radicals and radicals containing other elements than carbon and hydrogen. These labile molecules are seen to be of common occurrence in a wide variety of chemical reactions. There follows an account of photochemical decompositions and the free radical mechanism of polymerization and oxidation. Finally, the subject is carried into the field of biochemistry, and the free radical mechanisms of biological oxidation are critically discussed.

The book is complementary in many ways to Dr. E. W. R. Steacie's "Atomic and Free Radical Reactions", first published at about the same time. Dr. Steacie is particularly concerned with the kinetics of the reactions of the simple free radicals mostly in the gas phase, and gives a very detailed and comprehensive account of these reactions and their associated activation energies in so far as they are known. Dr. Waters, on the other hand, presents a more general and very readable account of a wider field and devotes more attention to reactions in solution. Each author is therefore writing particularly about that part of the subject to which his own research has contributed much.

Apart from the value to research workers in this relatively new branch of chemistry, Dr. Waters' book will be read with interest by a much wider public who want a general and lucid account of a subject which has applications in so many other branches of chemistry and biochemistry. In particular it will be of great interest to organic chemists in presenting a means of understanding better what are now almost classical methods of organic synthesis and preparation.

The Oxford University Press is to be congratulated on the production of this volume at the sort of price which is becoming rare in scientific literature. It is unfortunate that there is no term in the publishers' vocabulary with a meaning between 'new edition' and 'reprint' or 'new impression', for volumes of this kind which, though technically second editions, are not sufficiently changed to make their purchase necessary by owners of the first. In the absence of such a distinction a second preface or publishers' cover note indicating what changes have been made would be of value.

George Porter

STELLAR ASTRONOMY

An Outline of Stellar Astronomy

By Peter Doig. Second edition, completely revised. Pp. vii+168. (London: Hutchinson's Scientific and Technical Publications, 1947.) 10*s.* 6*d.* net.

THIS little book is designed, as the author unassumingly states, for readers who have "slightly more knowledge than that necessary for perusal of 'popular' astronomical literature". It is, in fact, a useful summary, remarkably complete for its size, of the present state of knowledge, and there will be many genuine astronomers, both amateur and professional, who will find it worth reading for the facts and opinions which it reports.

It is not, however, a text-book, and although it does not claim to be one it must be said that it would have been even more useful if it had approached the text-book ideal more closely in some respects. In particular, although the facts, and the conclusions from arguments, are clearly stated, the arguments themselves are frequently so much compressed that they lack clarity; no one, for example, who is not already familiar with Trumpler's work on open clusters and interstellar absorption will be likely to grasp the argument summarized on p. 28. In some places compression has resulted in actual errors; thus it is stated that the υ-component of proper motion is caused by the sun's motion, and in the formulæ for mean parallaxes based on the υ and τ components no mention is made of the fact that with the former the means are algebraical while with the latter they are arithmetical; also the sign of υ is not defined, but appears to be opposite to the usual convention. These two are almost the only formulæ presented in the body of the book, and they are not actually usable as presented.

There are a number of good appendixes, mostly devoted to formulæ; one on indirect methods of parallax determination omits all notice of the three methods dealt with in the book proper, which may mislead some readers. There is a short bibliography at the end of each chapter, but it is quite clear that much more extensive and detailed references could easily have been given; they obviously were used by the author, especially in the appendixes (where scarcely any are quoted), and they would also have been valuable for elucidating the arguments in the text. There are a fair number of printer's errors, but most of these are minor. In spite of such criticisms the book well deserves a place on the shelves of working astronomers, in addition to having obvious value for the readers to whom it is more specifically addressed.

R. d'E. Atkinson

Atomic Energy Levels as derived from the Analyses of Optical Spectra

Vol. 1, Section 1: The Spectra of Hydrogen, Deuterium, Helium, Lithium, Beryllium, Boron, Carbon, Nitrogen, Oxygen and Fluorine. By Charlotte E. Moore. (Circular of the National Bureau of Standards, 467.) Pp. iii+75. (Washington, D.C.: Government Printing Office, 1948.) 50 cents.

THIS is apparently the first of a series of reports from the National Bureau of Standards, Washington, and covers the elements of the first row of the Periodic Table. That very valuable book, "Atomic Energy States", by Bacher and Goudsmit, is now sixteen years out of date, and as it is not being revised this new series will eventually replace it.

The general arrangement follows closely that of Bacher and Goudsmit; but it is an improvement to have all spectra treated similarly with the ground-state of the atom taken as zero energy. This part is right up to date, including work up to late in 1947. The recent work of Edlén is fully treated, and many of his hitherto unpublished results are included. It is interesting to see the inclusion of the ^5S level of C I at 33735 cm.$^{-1}$; this has been the subject of much discussion in connexion with the energies of carbon bonds. The introduction to the series has not yet been published, and that is quite understandable; but it is a pity that a brief key is not given to the mysterious symbols (T., G.D., etc.) which appear after the references. The present circular does not contain any diagrams of term schemes; but charts of predicted terms in the spectra of some isoelectronic sequences are promised later. This work of compiling atomic energy-levels is an extremely valuable contribution to science, and these volumes will be indispensable to anyone who uses spectroscopic data. A. G. G.

Finite Differences and Difference Equations in the Real Domain

By Prof. Tomlinson Fort. Pp. viii + 251. (Oxford: Clarendon Press; London: Oxford University Press, 1948.) 25s. net.

IN his preface, the author states that this volume includes material for a course in finite differences as well as a treatment of a number of special topics. A selection of material was necessary in order to bring the work within reasonable compass, and also to follow somewhat the special interests of the author. The very large theory of difference equations in the field of analytic functions of a complex variable has been completely omitted. This has carried with it the omission of a variety of related subjects, particularly in infinite series.

The first six chapters constitute a readable account of the applications of the finite calculus to differencing, summation, the polynomials of Bernoulli and Euler, numerical differentiation and integration, and interpolation. The remaining eleven chapters are mainly devoted to a study of the linear recurrence relation, that is to say, the linear difference equation in which the independent variable assumes integral values. It is in this topic that the author's main interest clearly lies, but the powerful and elegant operational methods which are available in this field are barely touched. On the other hand, there are interesting and useful accounts of the linear recurrence relations of the first and second orders with periodic coefficients. L. M. M.-T.

A Bibliography of Chemical Research in South Africa, 1910–1939

Compiled by Dr. Herbert Coblans. (Published for the Natal University College.) Pp. ix + 25. (Cape Town: *African Bookman*, 1947.) 7s. 6d.

THE author of this slender volume explains that the lack of bibliographical tools is a real handicap to research workers in South Africa, since the proceedings of the learned societies there have no cumulative indexes. Many of the papers listed, however, have been published in European or American journals, and chemical research is perhaps one of the best abstracted fields of work. The information given can, therefore, be of special interest only to those chemists who wish to know which publications were by South African authors. Full titles of the papers are given and the references to the publications. The classification is according to subjects in decimal order based on the general principle of increasing specialization. In each section, the order is according to year of publication. Dr. Coblans is himself a chemist, and the accuracy of the book may, therefore, be taken for granted. His position as librarian of Natal University College vouches for his bibliographical ability. It is clear from the contents of the book that chemists in South Africa are making notable contributions to research in their subject, as was, in fact, generally realized before its publication.

Studies and Essays presented to R. Courant on his 60th Birthday, January 8, 1948

Pp. viii + 470. (New York and London: Interscience Publishers, Inc., 1948.) 33s.

PROF. R. COURANT, formerly of Göttingen and now of New York, who is known to all mathematicians by Courant and Hilbert's "Methoden der Mathematischen Physik", attained his sixtieth birthday on January 8, 1948. To commemorate the occasion a number of his friends and colleagues were invited to contribute articles for a volume to be presented to him. Among the thirty-eight mathematicians who responded to this invitation are included such well-known authorities as Harald Bohr, Carathéodory, Franck, Hadamard, Kramers, Neugebauer, Pólya, and Van der Waerden. The papers cover a wide field, corresponding to the wide range of Courant's own work, and some of them are direct developments from this work. Although most of the authors are foreign, all but six of the papers are in English.

The Cathode Ray Oscillograph in Industry

By Dr. W. Wilson. Third edition, revised. Pp. xii+252. (London: Chapman and Hall, Ltd., 1948.) 18s. net.

BECAUSE of demand the present text has been off the market for some time, so the author has taken the opportunity of bringing some of the matter up to date and also of incorporating applications of cathode-ray tubes which have been recently released. Not only would radar have been impossible but also many of the measurements and controls of industry would have been impracticable without the cathode-ray tube. It has become a tool of precision and a means of display. The types available and applicable to special tasks in industry are so well treated by the author that this edition will also soon be disposed of. L. E. C. H.

THE PASSING WORLD*

By Sir HENRY TIZARD, K.C.B., F.R.S.

President of the British Association

SEVENTY-SIX years have passed since the British Association met in Brighton. Great changes have taken place in the world since then. Nothing illustrates the lapse of time more strikingly than one passage in the address of the president, Dr. William Carpenter. After referring to the expedition sent for the relief of Livingstone he added :

"While we give a cordial welcome to Mr. Stanley, let us glory in the prospect now opening, that England and America will co-operate in that noble object which—far more than the discovery of the Sources of the Nile—our great Traveller has set before himself as his true mission, the Extinction of the Slave Trade."

And nothing better illustrates the truth of the old saying that the more things change the more they remain the same than the address of the president of the Section of Engineering, Mr. Bramwell. He discussed the coal problem. He directed attention to the alarming increase in the cost of coal, which had doubled in a year. "I am aware", he said, "that the subject of coal is a hackneyed one", but the startling facts to which he referred "force us seriously to reflect upon the use and also the abuse of coal." He discussed the inefficiency of domestic fires; but said he would rather put up with the whole of our present domestic discomforts, and even with the loss of heat than resort to the stove as a remedy. "But let not users of coal remain indifferent to savings on their present consumption until those improvements are discovered by scientific men ; on the contrary, let them forthwith do everything in their power to reduce the consumption to the extent to which present science and, in some instances, present practice show the consumption can be reduced."

At the same meeting the famous physiologist, Prof. Burdon Sanderson, referred to the backwardness of physiological research in Britain as compared with Germany. "If a man wants to be a physiologist", he said, "he must, as things at present stand, study medicine. There is no logical reason for this : for although medicine ought to be built on physiology, there is no reason why a physiologist should know anything about the art of curing diseases." However, it was a most encouraging sign of the times that Trinity College, Cambridge, had "condescended to provide a place for physiologists to study and labour in, from which . . . one or two valuable researches have already sprung." We shall all agree that the condescension of Trinity College has been amply rewarded. There is perhaps still room for similar acts of condescension on the part of wealthy corporations.

There is, finally, another passage in Dr. Carpenter's address which is of special interest to me. He describes how he urged on his friends in the Admiralty the importance of organising a new expedition to circumnavigate the world, and how the Royal Society followed up his preliminary inquiries with a formal request. The Admiralty agreed, and the good ship *Challenger* was then fitting out at Sheerness, and being equipped with the most modern scientific apparatus. Captain Nares had been chosen to command the expedition, and Prof. Wyville Thomson to lead the scientific staff. The reason of my special interest is that my father was the navigating officer of that famous ship.

All that the British Association set out to achieve over a hundred years ago has been accomplished. Long past are the days when the public estimation of science had fallen so low that, to use the words of David Brewster in 1830, no scientist enjoyed "the favour of his sovereign, or the friendship of his ministers ;" and when an alarmed Dean of York was moved to publish a pamphlet entitled, "The Bible defended against the British Association", which attained such a popularity with Victorian churchgoers that it ran through five editions in one year. We men of science have little to complain of now. The public estimation of science stands higher than it has ever done in Great Britain. The Royal Society enjoys a prestige unequalled since the early part of the eighteenth century. The Great War, which has been succeeded by an uneasy peace, grimly demonstrated that the country whose rulers neglect science is lost ; and public men in England now display a touching but alarming faith in the power of science to solve any national problem, however serious. The time is near when, as Huxley warned us over sixty years ago, science, like Tarpeia, may be crushed with the weight of rewards bestowed on her. Let us then beware, when all men speak well of us, and be critical of ourselves. Let us ask whether we are claiming too much in some directions, and doing too little in others ; let us consider in fact whether the great forces of science, on the proper exercise of which all social progress depends, are in balance.

The Progress of Sixty Years

It was with some such thoughts as these that I chose the title of my address. It is taken from Dr. Johnson's well-known advice to the poor scholar in the "Vanity of Human Wishes."

> "Deign on the passing world to turn thine eyes,
> And pause awhile from letters to be wise."

I propose to pause awhile from the fashionable discussions of Science and the Community, Science and Education, and the like, and to invite you to turn your eyes on the passing world. For it is passing —from one state of unstable equilibrium to another. I say unstable, for many many years will pass before the dreams of those who look forward to a world Government which will bring not only peace but also happiness to all, will come true. But if it must be in unstable equilibrium for many years to come, let us at least strive to balance it so that the chance of a major catastrophe is made as small as possible. Science has much to contribute to this aim ; but just as no man can aim a rifle accurately without a backsight as well as a foresight, so must we provide ourselves with both, if our contribution is to be worth while. The backsight is history; it can be fashioned accurately by study. The foresight can only be fashioned from our knowledge of the state of science as it exists to-day, and from what we know is possible. It cannot be so accurate as we could wish, because we cannot foretell the effect of discoveries of which we have no inkling at present.

---

* From the Presidential Address, delivered at Brighton, on September 8.

My backsight shall not be too far back. In considering the future we shall not gain more by studying remote history than we gain perceptibly in accuracy by lengthening the barrel of a rifle. I shall sight, somewhat arbitrarily, from the year 1885; not 1685. It happens to be a convenient year for me, as it was the year of my birth. It happens, too, that it marks almost the close of the stagnant period of nineteenth century science, when many men thought that "our power to discover new experimental facts was practically exhausted." But new men were coming on, and new ideas were hatching. J. J. Thomson had just been elected to the Cavendish chair of physics at the scandalously young age of twenty-eight —a thing which would not be tolerated nowadays. Charles Parsons had patented the steam turbine in 1884, and demonstrated a model at the Inventions Exhibition in 1885. Gowland Hopkins had been appointed assistant to Sir T. Stevenson, the Home Office analyst, and was studying, in his spare time, the pigments of the wings of butterflies. Three years were to pass before he was able to begin his formal education in science as a medical student at Guy's Hospital. Charles Sherrington was fighting cholera in Spain and investigating its causes, and Rutherford was carrying off all the prizes at school in New Zealand. Of these great men, whom many of us had the privilege of knowing, only one is alive to-day. Sir Charles Sherrington is the oldest living president of the British Association. We send him our respectful and affectionate greetings.

It is understandable that none of these events, which in their different ways were to have a more profound effect on history and society than any legislation, or rise or fall of governments, created any public interest, except perhaps the exhibition of the turbine which was considered ingenious but wholly unpractical. In other respects the events of the year 1885 followed a normal course, judged by modern standards. There was fighting in what we now call the Middle East, which ended in the massacre of British troops, and of their leader, General Gordon. Our Russian friends were told that anxious though we were to preserve our friendship, there was a limit to patience. But the British public soon recovered from the shock of Gordon's death, and refused, so far as I can judge, to be seriously disturbed by the prospect of war. It must be remembered that they were denied the blessings of broadcasting, and other modern equipment for the ready circulation of bad news. They were far more exercised by the prospect of cholera spreading from Spain. They had reason for their anxiety, for the great majority remembered the epidemic of 1866 when 14,000 deaths from cholera were recorded. On the whole, the people of England jogged along in a deplorable state of confidence, which was, however, justified by events, for nearly thirty years of peace followed, broken only by minor wars which had no perceptible effect on the growth of material prosperity.

In 1885, after a few years of depression, during which nearly 700,000 men and women left the country to seek better opportunities overseas, the United Kingdom was still the greatest manufacturing nation of the world. An enthusiastic commentator wrote at the time that "the material greatness of the country is amazing—it exceeds that of any other Empire, Ancient or Modern. But the moral greatness is even grander . . ." Unemployment was sometimes high in particular trades, such as shipbuilding, but between 1885 and 1914 it was never alarming, and was often as low as 2½ per cent of the gainfully employed. The United States were not then serious competitors; imports of iron and steel manufactures from the United States only reached an annual value of £500,000 in 1890, but from then on steadily increased. Germany was considered a more serious competitor. In the pursuit of science she stood first among the nations, and she was applying the methods and results of scientific research to industry on a scale and with a determination that far surpassed her rivals. At the meeting of the British Association in 1885 the president, Playfair, sadly recorded that in science "Oxford and Cambridge are still far behind a second-class German University", and that "in Great Britain we have nothing comparable to the great technical college of Zurich". Germany kept her pre-eminence in applied science until 1914; but it is perhaps worth noting that she never equalled the industrial prosperity of England, judged by the test of real national income. She might have done so, had not her rulers believed that by war they could find a short cut to the happiness and wealth that could have come in the natural course of events to a hard-working and highly educated people anxious to live in peace with the world. The terrible fate of Germany is a tragedy that affects us all, the last act of which perhaps we have not yet witnessed.

Many of the numerous comforts and luxuries which are now within the reach of every diligent working man in England are the result of invention or scientific discovery in or about the year 1885. I have already mentioned the steam turbine, which by making possible the generation of electricity on a large scale provided in the most convenient form the power on which industrial productivity so largely depends. Kelvin lit his house with electricity in 1881, and the telephone was invented in 1876; but they were both scientific curiosities in 1885. The modern 'safety' bicycle first appeared upon the roads in 1885; it was the manufacture of a reliable chain that made it practical. The first Dunlop pneumatic tyre appeared in 1888; but the idea was not then wholly new. Like many other things before and since, it had been invented before its time, that is to say, before manufacturing technique was sufficiently advanced to make it practical. Edison, in 1885, was in the full tide of his inventive genius. The first talking machine had been demonstrated in 1877, and in 1885 he was busy experimenting with motion pictures. Swan, whose share in the production of the carbon lamp is well known, invented a practical process for the manufacture of artificial silk in 1883. The typewriter in its early form was then quite old; but difficulties in manufacture prevented it from becoming available in quantity until towards the end of the century. The internal combustion engine which, in peace and war, has had a greater influence on society than any invention since that of printing, was developed from Otto's experiments in 1877. The intrepid Daimler drove a bicycle powered by an internal combustion engine of his own design in 1885; and the first motor-cars were sold to the public. In the field of applied chemistry one far-reaching development to recall is the electrolytic production of aluminium in 1885. Aluminium was then a rare metal costing £18 a pound. It now costs 10d. a pound.

Thus, although the science of physics was languishing until the discovery of the electron, X-rays and radioactivity in the closing years of the century, it was a time of enterprise and progress in engineering practice. Britain prospered. In 1897, the year of the spectacular triumph of the *Turbinia* at Spithead, we exported goods to the value of one quarter of everything we produced. Ten years later we shipped overseas nearly one third of the whole national output of goods of all sorts—on farms, in mines, or in factories. If we were doing so to-day we should have little cause for anxiety. Perhaps it was this very prosperity that caused us to fall behind in some branches of industry, for when there is little unemployment and when the standard of living is obviously rising in all sections of the community, there is an excusable tendency for manufacturers to go on doing what they know they can do successfully, rather than to launch out in new directions. Is not this, rather than the neglect of science, the chief reason for the fact that synthetic dyes and fine chemicals were manufactured in Germany, rather than in their original home England ? Whatever the answer to this question, the fact remains that when war started in 1914 we were caught off our balance. We found ourselves dependent on our enemies for many essential products and instruments on which our power to make war, and to maintain health, depended. But, to everyone's surprise, we also found that the reserve of scientific ability in the country, though not large, was high enough in quality to overcome the immediate dangers with remarkable speed. Young men from the universities who had spent their time on researches of no practical importance applied themselves with success to problems often completely outside the range of their previous studies. We had the same experience in the Second World War, although fortunately we also had the foresight to prepare for some of the worst dangers beforehand. There is a clear lesson, I feel, to be drawn from this experience. Whatever may be done, in a burst of public enthusiasm, to support and promote schools of research at universities, nothing should be allowed to lower the quality; and size, beyond a certain point, undeniably does. A research laboratory, of whatever nature, is like a living cell. Once it reaches a certain size, which may differ with the nature of the subject, it must divide or die. When a young graduate tells me, as one did recently, that he was going to do research because it got him off military training, it makes me wonder whether we are not already overpopulating the research departments of universities.

The shock caused by the exposure in 1914 of our industrial shortcomings, which had been concealed by the apparent prosperity of previous years, led to a great increase of research by industry and by Government. The National Physical Laboratory, which had been of inestimable value during the War, extended the scope of its work. The Department of Scientific and Industrial Research, which was founded in 1915, established other Government research laboratories, and encouraged the formation of research associations to serve the needs of the older scattered industries. University schools of science were greatly enlarged, and under the influence of the great men of the inter-war period there was a surge of discovery which put Great Britain in the van of progress in nearly all branches of science. We became a scientific nation. The newer industries, such as the viscose and radio industries, which had been founded on science, rapidly developed. The chemical industries took on a new and active lease of life. Germany, badly disorganised by defeat, ceased for many years to be a serious competitor in the world market.

Many of us must have felt confident that when leadership in scientific and industrial research was allied to experience in commerce and manufacture, and to skill in craftsmanship, our country would have little difficulty in maintaining its position among the nations of the world. We have been disappointed. I am referring now not to the acute difficulties of the present day, but to the general trend of events before and after the First World War, when in spite of a nearly continuous advance in national income and standard of living, Great Britain gradually lost her pre-eminent position. We cannot attribute this relative decline to the 1914 War. That War had curiously little effect on our economy. Nor can we attribute it to the world depression in the 1930's. The depression affected us much less than many other nations, for owing to the great fall of prices of food and raw material the terms of trade moved sharply in our favour. During 1930–38 the volume of exports necessary to purchase a given volume of imports was only two thirds of what it had been during 1885–1914. To what then shall we attribute the relative decline ? Shall we argue that a main cause was that research was on too small a scale, or shall we seek for other reasons ?

Research and Industry

Let us first be clear about what results we expect to come from the application of science to industry. The primary object of industrial research is severely practical. It is not to enlarge the boundaries of knowledge, or to publish scientific papers, although that may be a prerequisite or a consequence. The object is to do something that has never been done before, or to do things better than they have been done before. And it has, or should have, the special object of reducing the labour required to supply the material needs and wants of men. All social progress such as spread of education, promotion of health, opportunities for leisure and healthy recreation, must depend on the power of science and technology to increase the productivity of industry. The rate of social reform is set by the rate at which productivity increases; and social unrest is inevitable if reform lags too far behind the advance of technology, or is pressed too thoughtlessly before it. So we must judge the effect of industrial research not merely by the new comforts and luxuries that it produces, but also by the rate of improvement of existing processes.

In Britain, which depends more than any other country on international trade, and which can continue to maintain its present population only by exchanging manufactured articles for food and raw materials, the productivity of labour is of primary importance, for unless it is as high as, or higher than, in other manufacturing countries, we shall not be able to compete in the markets of the world. And the productivity of labour in Britain is far lower than it could be if the results of past research were more resolutely and continuously applied. We find this particularly in certain industries of great importance. In the coal industry the results are painfully obvious—

the coal raised per man employed is now lower than it was thirty years ago, when nearly all coal was hewed by hand. Research on building has been intensively pursued since the Department of Scientific and Industrial Research was founded. Those responsible for its direction have not been content with the publication of papers giving the results of their investigations but have built demonstration houses for other builders to inspect and study. But are better houses now being built with less labour than twenty years ago? I doubt it; if not, the research has had as yet little influence on practice. The Shirley Research Institute for the cotton industry is well known for the range and excellence of its work; but productivity in the cotton textile trades is lower than it was fifteen years ago and much lower than in some other countries. Taking British industry as a whole, productivity is far lower than in the United States. In both countries about 40 per cent of the population is gainfully employed. In the United Kingdom the proportion engaged in manufacturing, building and civil engineering, which covers the production of all capital and consumer goods (other than minerals or food) is now a little less than 18 per cent of the population. In the United States the corresponding figure is 12 per cent; and yet in proportion to the population the volume of production is far higher than in the United Kingdom.

The causes of the relative productivity and wealth of nations are, of course, many and complex. We gained our supremacy in the nineteenth century because we excelled in engineering genius and were the first to use mechanical power on the large scale for manufacture and transport. Our population grew rapidly because we were prosperous, and it paid us to become a food importing nation because the productivity of labour in the secondary industries was so much higher than in agriculture. But conditions have changed in the course of time. We no longer have any outstanding natural advantages, and we must expect that given approximately equal skill in technology other nations with greater natural advantages will surpass us. Only by maintaining leadership in the application of science can we hope to keep our position among the great nations. So it is not surprising that the United States, and Canada, for example, with their great natural resources, and abundant supply of cheap power, should have passed us in wealth and productivity before the War. It would have been surprising if they had not. But it is by no means so easy to explain why Switzerland, which in 1885 possessed a national income per head about two thirds of that of the United Kingdom, should have equalled us in prosperity by 1939; or why the industrial productivity of Sweden, a country that has no coal, should have been rising so much more rapidly than ours in the years between the wars. These two countries cannot be said to possess natural resources superior to ours; nor can it be argued that in the quality or quantity of scientific and industrial research they excel us. But I suggest that they, in common with the United States, possess a higher average standard of technology than we do, and have a much greater proportion of men of high scientific education in executive control of industry. I quote them in support of my view that it is not the general expansion of research in Britain that is of first importance for the restoration of its industrial health, and certainly not the expansion of Government research remote from the everyday problems of industry. What is of first importance is to apply what is already known.

The fact is that all really new developments of industry are the product of the work of very few men. In general, knowledge in the physical sciences now accumulates at a rate much faster than it is, or possibly than it can be, applied in industry. There is a vast amount of knowledge waiting to be used. No new discovery, in any field, is likely to have so quick and beneficial an effect on British industry as the application of what is already known. We hear, for example, of the possibility of the production of power from atomic sources of energy. I do not think that anyone will be rash enough to prophesy what discoveries of real industrial importance will result from the researches now in progress; but I shall certainly assert that the production of power from uranium cannot bring such economic benefits to Britain within twenty years as would the practical application of known methods of economizing coal. Mr. Bramwell's advice in 1872 is still sound, and is always likely to be. Even in those fields of industy where science and development have been most in step, we find scientific knowledge far ahead of practice. In aeronautics, for example, research has shown, without any shadow of doubt, that it should be possible to design aircraft far more economical in fuel consumption than present aircraft. For the next step we need bold and highly skilled engineering rather than more fundamental knowledge: if it is successful, air transport, instead of existing precariously on subsidies, will compete on level terms with the train and ship for long-distance passenger travel. Indeed, a revolution in transport is in sight. Shall we leave it to be encompassed by other nations, or shall we show the way? The answer depends on whether we shall encourage enterprise and adventure in engineering.

War as Applied Science

Although I have been interested in the problems of industry for many years, I have never been closely concerned with its conduct. But for much of my working life I have been intimately concerned with that peculiar business called war, which is as old as agriculture, which is subject to the most violent booms and slumps, the cause of which we do not understand, and in which the incentive to succeed is greater than any profit or ideological incentive in civilian life. There is a healthy human rivalry between the various units and companies into which the business is divided. Sometimes it may be thought that this rivalry is carried too far; but all are working for the same cause. In my own life-time I have seen this business change from one in which the practical man considered he had little to learn from scientists, into one in which scientists are concerned with its every aspect, from policy making to the actual conduct of operations. We shall all hope that this business is moribund, and shall do our best to kill it: but in the meanwhile it is possible that other old industries have much to learn by studying the principles of its successful conduct.

In the first place, let us note that the managing directors, the chiefs of staff and commanders, are all carefully selected highly trained professional men, who have gained their experience in a hard school, and who, at intervals in their career, have had the opportunity to study, at staff colleges and elsewhere, the fundamentals of their trade. The managing directors do not have the final responsibility for policy, but have a great influence on the decisions. Secondly, the technical efficiency of the business is entrusted to a body of engineers and technologists, who have had an advanced specialized education and experience, and who are in personal contact at all levels with scientists who are concerned with research and development. This secures that in all research, however recondite, there is a practical objective, and that there is also a continuous urge to improve in detail. The scientist is primarily responsible for research, but experienced engineers take part in it. The engineer and the scientist are jointly responsible for development. But there is no part in the whole process from research to production and use that is neglected, and none in which scientific thought and influence are wholly absent. One point of special interest is that far more attention—but perhaps still not enough—is given to the study of man in relation to the machines he has to operate than in any branch in industry.

It does not need any profound research to show that the British industries that are now best standing up to the strain of adverse circumstances are those that most nearly approach the system I have described. The chemical industries, for example, have gradually developed a similar organisation over the last thirty years. Neither research nor development has been neglected, and management is in the hands of men highly educated in pure and applied science. The result is that our chemical industries are a source of great and growing strength in peace and war. Forty years ago they were far inferior to the German industries; now they have little to fear from any competitors. In the steel industry, the efforts of which now merit our admiration, it is not uncommon to find management and direction entrusted to men of the highest reputation in science and technology. Turn your eyes on any industry in the world that is similarly organised, on the steel industry of Australia, for example, or the photographic industry of the United States, or the machine-tool industry of Switzerland, and you will find that they are the best able to weather the storms and take advantage of the fair winds of trade. Further, I shall ask you to note that in such industries human troubles, if not entirely absent, are inconspicuous. This, I think, is to be expected, for most men are happiest and do their best work when new things are being attempted, and when adventure of some kind relieves the monotony of a daily routine.

It is a mistake to suppose that science advances rapidly in a war. Certain branches of science may receive a special stimulus; but on the whole the advance of knowledge is slowed. What is striking in a war is the rapid solution of practical problems by the use of previously acquired scientific knowledge and technique. It is a mistake also to attribute this success to the fact that cost does not matter. Cost matters a great deal; indeed the purpose is always to achieve the end in view with the minimum cost of lives, labour and material. Finally, all depends on good design and production. Our weakness in the War was not to be found in the judgment of what was best to do, nor in the scientific work necessary to do it. It was when the stage of design and production was reached that we fell short of the best standards. The magnetron, which contributed more to the success of the Allies than any other single invention, was a product of British science; but it had to be redesigned in the United States for economical manufacture. Penicillin, the greatest practical achievement of medical research during the War, also originated in Britain, but unless American skill in large-scale manufacture had been available, many thousands of men, who now enjoy a healthy life, would have died.

We now see history repeating itself. After the Second World War, as after the First, there is a cry for more research, in industry, and by Government, and a strong demand on the universities to expand their schools of science. Temporarily this enthusiasm is having an unfortunate effect, for the schools are getting starved of teachers; and unless a high standard of teaching is maintained in our schools, the next generation of scientists will suffer. In the long run, too, the expansion of research will fail to produce the hoped-for result unless we promote at the same time education in the higher branches of technology, and unless the technologist takes his rightful place in industry. Throughout the nineteenth century, the advances in engineering that made so great a difference to our prosperity, were the product of inventive rather than of scientific genius. Even the steam turbine, though its conception was founded on long-established physical principles, was brought to a high pitch of practical efficiency with very little assistance from scientists. But we live in a different age. Pure invention still has its place; but industrial prosperity will depend more and more on the continuous application of science to industrial practice. Unless we can raise our standard of technology, unless there are many more men in executive positions in industry whose practical experience has been preceded by a scientific eduction, we shall inevitably fail to keep our place among the great manufacturing nations. President Playfair's remark about Oxford and Cambridge is no longer true. Cambridge has long been recognized throughout the world as a great home of science; and it is not merely devotion to my *Alma Mater* that prompts me to say that Oxford is now not far behind. But I fear that it is still true that in Britain we have nothing comparable to the great technical college in Zurich.

Advances in Public Health

I turn now to another branch of applied science, less spectacular in its results to the ordinary citizen, but far greater in the benefits that it has brought to mankind during the last sixty years. The physical sciences have given men comforts and luxuries that are obvious to all. The aeroplane, the cinema, the broadcasting and television receiver, the domestic refrigerator, and many other familiar things which were unknown even at the end of the nineteenth century, are positive results of scientific research. Health, on the other hand, is in a different category. The ordinary citizen sees little connexion between the advance of science and the fact that he is healthy; it is, he feels, a quality that other people may lack, but is his by right of a superior heredity or habit. Ill health, on the other hand, while a fault in other people, is a misfortune in himself, and a serious reflexion on the state of medical science. How many men now living in Britain have any real conception, I wonder, of the astonishing advances in the prevention and cure of disease that have taken place in the last sixty years, and of how they have come about? Where is the cholera with which I was threatened as a child if I drank unboiled water? Its last appearance in England was in 1893; it was soon stamped out, and there has been no epidemic since. We are puzzled and alarmed by its appearance even in a country like Egypt, with its low standard of sanitation. Many other diseases which were common in 1885 have practically disappeared or are under control. Those that remain, will, without doubt, be conquered in the end by the advance of knowledge.

In 1885 the crude death-rate was twenty per thousand; now it is twelve. In 1885 one in every seven children died during the first year of life; now the figure is one in twenty-five. In 1885 a young man of twenty could expect on the average to live for forty-one years; now his expectation of life is forty-eight years. And it is not merely that he will have a longer existence, but that he can look forward to a far healthier life. Where can one now find the stunted children with distorted limbs, who were a common sight in the industrial towns of England when I was young? If it were possible to compare a random sample of young men and women from the poorer districts of London with their grandparents at the same age, it could scarcely be believed that they came from the same stock. Only those few medical men who had the duty of examining recruits for the Army in the First and the Second World Wars can have any vivid appreciation at first hand of the changes that have come about in a single generation through the study of nutrition and preventive medicine.

These great advances have been mainly due to the fundamental researches of very few men, and to the vigour and good judgment with which their work has been extended and applied in practice. Never has public money been better spent than on this branch of applied science; and never has such a small investment yielded such a rich return to the nation. The recently published report of the Medical Research Council, covering the war years 1939–45, is a document of the highest scientific and historic importance which can be read with interest and profit even by laymen who are unfamiliar with the jargon of medical men. In 1939 the Medical Research Council confidently stated that:

> "The destructive power of arms will indeed have increased immensely since 1918 if it overshadows the advances in knowledge for the saving of life which modern discovery has placed at the disposal of medical men. If a strict comparison were made between what science has done to increase war mortality and what medical science has done to lessen these lethal effects, there is good reason to believe that the latter would be an easy winner."

Omit the word 'medical' in the last sentence, and I think it will be agreed that no prediction has been more amply justified. Nor should we too quickly assume that new destructive weapons evolved by physical science will in the future reverse the decision. In spite of all the hazards of bombing, the average civilian death-rate during the years of war was lower than it was during the immediately preceding years of peace. The deaths in the fighting services were less than one third of the deaths in the 1914–18 War; and more than 80 per cent of the wounded have been restored to normal life. In spite of all the difficulties caused by the submarine blockade, and the shortage of food, which still persists, we are a healthier nation than we were in 1939. Whether we are as energetic is another question.

Our American allies have the same tale to tell. Four years of hard fighting in Europe and the Pacific caused fewer deaths than in the American Civil War, when the population of the United States was only one fourth of what it is now. It was only in Germany, East Europe and the U.S.S.R. that war counted its victims by millions, and then not through the destructive forces of science, but because of the brutality of human nature at its worst.

Nevertheless, the progress of preventive medicine is giving rise to social changes of great complexity, which will seriously affect the peace and prosperity of the world unless their consequences are studied with care, and their possible evils counteracted by wise and far-sighted action. In all countries which have a high standard of education, such as our own, the rise in population which follows a rapidly decreasing death-rate has been kept in check by a voluntary control of births. As a result the average age of the population has considerably increased, and is increasing; the proportion of the population of England and Wales that is more than sixty-five years of age is now nearly four times as high as it was in 1885. This in itself does not yet present any serious problem, for, as the proportion of children is much less than it was, the proportion capable of productive work, between the ages of fifteen and sixty-five, is actually somewhat higher than in 1885. No fundamental difficulty, from this cause, is likely to arise for many years to come. But the population of the world as a whole is now increasing by 1 per cent a year, and its distribution is such as to make it extremely doubtful whether the supply of food can keep pace, even with the present low standard of nutrition. It is the advance of science that has made this possible. War, pestilence, and famine have kept the population within bounds since the dawn of history. War has ceased to be effective; pestilence is rapidly losing its power; only famine is left as a brake until education takes its place. Is famine inevitable, or will science again come to the rescue, as it has done before? I do not think that the danger of the present position is yet fully realized, in spite of all the work and publications of the United Nations Organisation, and in our country the well-informed debates and warnings of the House of Lords. People remember only too well the apparent over-production of food in the 1930's, and forget, or do not know, that since then the population of the world has increased by some 300 million people.

A single example of what is now happening, and will probably happen on an ever-increasing scale, may help to illustrate the problem. Malaria has always been one of the most potent instruments of population control. It is endemic in most tropical countries. In the Far East it has hitherto been an antagonist more to be feared than the armed forces of an enemy. In the Second World War it was defeated by the controlled use of 'Mepacrine', a German drug, which is being replaced by an even better product of British research. In addition, the potential importance of the insecticide D.D.T. for the elimination of malaria-carrying mosquitoes began to be recognized toward the end of the War.

In 1944, Sir Robert Robinson, Prof. J. L. Simonsen, and Dr. Harold King visited British Guiana on a special mission. British Guiana has a population of roughly 400,000. Accurate statistics of the fluctuation of population do not exist; but it is probable that it has remained stationary for the last twenty years. Two thirds of the population used to live under conditions of severe endemic malaria. The birth-rate was low, and the infantile and adult mortality high.

The particular type of mosquito which is the carrier of malaria, and also of yellow fever and filariasis in the Colony, lives and breeds in the wooden houses, and not in swamps. It is thus peculiarly susceptible to attack by insecticides. The British mission advised a comprehensive trial. They were fortunate in finding a most experienced and progressive officer in Dr. Giglioli, honorary Government malariologist. Their advice was taken; operations were started in 1945, and at the time of speaking it is probable that the whole population of the Colony has been protected. The annual cost of keeping the whole district under continuous control is of the order of five shillings a head.

Malaria is now rapidly disappearing from the Colony. I cannot quote valid statistics covering the whole population; but I have been supplied with exact information about a suburb of Georgetown with a population of about 3,000, and there is no reason to suppose that the results will not apply generally. In this village the death-rate was equal to the birth-rate during the years 1938–44 inclusive. The average infantile mortality during this period was about 250 in a thousand. It rose to more than 350 in 1944. D.D.T. control was introduced in July 1945. By the end of 1947 the birth-rate had doubled, and the infantile mortality had dropped to 67 in a thousand. The population is increasing by 10 per cent annually.

Population and Food Supplies

As the new methods of preventive medicine spread—and that there will be many more to come no one can doubt—we must expect the world population to grow at an even faster rate than it has done in our life-time, unless famine intervenes. Moreover, it will grow particularly in parts of the world that already have a high density of population, such as India, where the population is now increasing by five million people a year; and Egypt, where there are already 2,000 people to every square mile of cultivated land, and where it pays to have children as they are a source of labour and of profit to their parents at a very early age.

Exactly fifty years have passed since a president of the British Association last warned his audience of the danger of famine. Sir William Crookes was then alarmed at the prospective shortage of wheat. He produced evidence to support his conviction that England and all civilized nations stood "in deadly peril of not having enough to eat". But he qualified his gloomy forebodings by the statement that the chemist must come to the rescue of the threatened communities, and went on to discuss the possibility of the fixation of atmospheric nitrogen. If that were achieved, the future, said Crookes, could take care of itself, and "in days to come when the demand may again overtake supply, we may safely leave our successors to grapple with the stupendous food problem". The chemist did come to the rescue, and the plant breeder too, though not quite in the way that Crookes imagined; and now the day has came when we must grapple again with the problem. We must not encourage the easy thought that some entirely new development in science will solve it quickly; there is nothing in sight comparable with the importance of synthetic fertilizers. There are certainly some interesting investigations in progress, for example, the production of food yeasts from molasses, and of fats by the action of micro-organisms on carbohydrates. All that can reasonably be said about these new developments at present is that they show the need for fundamental research in an almost untouched field. They are very unlikely to lead to a new and substantial source of supply of food within the next thirty years. So far as Great Britain is concerned, we must plan our economy on the assumption that food will be both scarce and dear for many years to come. Its scarcity is obvious to us; its dearness is concealed by a policy of subsidies. I do not criticize the policy. I refer to it only because it tends to hide a state of affairs that should be realized by every thinking man.

One or two years of good harvests in the wheat-producing countries may go far to relieve the present troubles of Europe, and will be of great benefit to us. But the supply of wheat is only part of a larger problem. World food supply will only keep up with demand if the productivity of land is increased, and more land is brought into cultivation. The productivity of land in the United Kingdom is already high; much higher, for example, than in most European countries and in North America. The productivity of labour on the land has increased in recent years much more than the productivity of labour in any other old industry. One man working on the land now produces enough food for twenty-five of the population. New Zealand surpasses all other countries in both respects. It is a land blessed by Nature and improved by science. But few people realize that in our small country we now grow enough food for twice the population of Canada. There is still room for a great advance. There is a consensus of opinion among experts whom I have consulted that the production of food in the United Kingdom could be raised by 20 per cent within five years by a combination of measures, such as the improvement of grasslands, the conservation of grass for winter feeding, the control of pests and weeds, the extended use of fertilizers, and the development of large tracts of marginal land such as exist in the Highlands of Scotland. It is argued that, though this would need considerable capital expenditure, there is no direction in which capital expenditure would yield more certain dividends to the nation, or make a more substantial contribution to the balance of trade.

I find these views convincing. But even if all this were to come to pass, we shall still need to import food for twenty to twenty-five million people unless there is to be a large outward movement of population; and we must not lose sight of the fact that at least twenty million people are added to the population of the world every year, and that it is conceivable that in another seventy years, or even less, the world population will have doubled. Whatever other countries may do, it is our bounden duty, and the only certain way of safeguarding our future so long as we remain a large food-importing country, to develop our colonial territories, particularly the underpopulated African colonies, where the increase in population that would follow the control of disease and the increase of food supply would open fresh markets for international trade. This great task will call for the intensive application of science, in collaboration with other countries. The tale of plant disease in our Colonies, for example, is a sorry one. I shall predict that unless the prevention of disease among plants and animals, and all other scientific problems of the supply of food, are studied on the same kind of scale, by men of similar calibre, as are the problems of human health, chaos and misery will result. Whatever new comforts and luxuries may be provided in future by the advance of physical science, it is on the development of the biological sciences that the peace and prosperity of the world will largely depend. Until recently there have been far too few careers open to young biologists outside the field of the medical sciences. There has been nothing corresponding to the Colonial Service, which has offered to young administrators a life of adventure nicely seasoned with economic security. All members of the British Association will therefore welcome the intention of the Government to inaugurate a Colonial Scientific Service, and will hope that the conditions of service will be such as to attract young men of the highest quality.

Challenge of the Times

We live, indeed, in difficult times. But they are very interesting times; and difficulties are bracing to a nation which has not lost the resilience of youth. We must not get into the way of thinking of our great country as an elderly man who is told by his doctor that if he is very careful of his diet, and avoids all exertion and worry, he may look forward to some years of placid life before he dies. This is a time for adventure; for taking risks. Calculated risks, of course; but not so nicely or so lengthily calculated that they are taken too late. My contacts with universities and with industry are not now so frequent or so close as I should like them to be; but they are enough to convince me that the spirit of adventure in science is as lively as it ever was. It is that spirit which will largely determine the future. Many years hence, when a president of the British Association reviews the progress of the nation from the depths of bankruptcy to new and unsurpassed heights of prosperity and influence, he may well have occasion to refer, as I did at the beginning of this address, to the great influence of the work of a few young men who are now unknown to the public; and he may justly claim that the chief cause of the change was that we had found the right way to combine originality in science with enterprise and speed in its application.

SUMMARIES OF ADDRESSES OF PRESIDENTS OF SECTIONS

RECENT ADVANCES IN THE STUDY OF THE CRYSTALLINE STATE

In his presidential address to Section A (Mathematics and Physics), Sir Lawrence Bragg points out that X-ray analysis of crystals may be said to have attained its majority this year. Its importance has been recognized by the formation of an International Union of Crystallography, and it takes its place with the other branches of science which have unions of their own. Laue discovered the diffraction of X-rays by crystals in 1911; now most universities have an active centre devoted to the investigation of the arrangement of atoms in matter by means of X-ray diffraction. Sir Lawrence has worked in this field from the beginning, and takes the opportunity which this address affords to review what has been accomplished in little more than a generation. X-ray analysis is a typical border-line subject. Its successes are interesting to the chemist, mineralogist, metallurgist and biologist as well as to the physicist, and this is perhaps its most attractive feature.

In X-ray analysis in general, we are seeking to interpret the manner in which a substance diffracts X-rays owing to the spatial arrangement of its atoms. Two main lines of work may be distinguished. On one hand, there is the analysis of the pattern of the perfect crystal, where the atoms have taken up positions of equilibrium under the influence of the interatomic forces; from the conformation of the structure we can gain a deep insight into the nature of these forces. This study is principally of interest to the chemist, because it presents him with a scale plan of the chemical molecule and of the way molecules or ions are held together by the intermolecular forces to form a solid structure. The results of X-ray analysis have had a profound influence on chemistry and mineralogy and solved many problems. A steady advance has been made in tackling more and more complex molecules, and a stage has already been reached where such compounds as the sugars, strychnine, sterols and penicillin can be analysed, to take a few examples. We would like to pass on to the study of such high complexes as the molecules which form part of living matter—nucleic acids, proteins and others.

The other side of X-ray analysis is concerned with what we might call the 'geography' of atomic arrangement in matter. The perfect crystal is an ideal which is rarely attained. Even if the substance is pure it is composed of a mass of crystals, and we are interested in the size and shape of the crystallites and their growth, in allotropic change, and in their preferred orientation and state of strain after mechanical treatment; if complex, we are interested in the fitting together of the crystallites of different kinds. Metastable structures often exist in which there is partial separation into regions of different composition, while a continuous crystal lattice is preserved though in a distorted form, as in the permanent magnet alloys, in martensite, or in age-hardening alloys. We can study the distortion of the lattice by the thermal waves at high temperatures. Amorphous and semi-crystalline matter can be examined. All these aspects of structure are of prime interest to the physicist and metallurgist. They are vitally interesting to the technologist, because the geography of the structure has a profound influence upon its mechanical, electrical and magnetic properties.

In this address, Sir Lawrence reviews the active centres carrying out X-ray investigations in Great Britain; examples are given of recent work, presenting a picture of what has already been achieved, and indicating the lines of exploration which are now being pursued.

SPECIALIZATION AND CULTURE IN CHEMISTRY

PROF. JOHN READ, president of Section B (Chemistry), deals with some of the problems of increasing specialization in chemistry. The growing burden of new knowledge in chemistry, as in science generally, has created many new problems for the student, teacher and research worker. These problems are largely bound up with the growth of specialization. A fundamental problem confronting the chemist is that of acquiring a proper education leading to a cultured outlook and fitting him to take his place in the world of men and affairs. What steps can be taken to combat the narrowing outlook which threatens to affect science students at all levels, and to provide for their social, cultural and spiritual needs ?

Formerly a chemistry student was trained to become an all-round practitioner of his art ; but latterly the vision of the student and research worker has narrowed. We have entered into an age of team-work. Chemical science has been aided nobly by such work ; but the individual worker is liable to sacrifice a great deal in the process.

The mental effect of an unrelieved absorption in a specialized field of science has been vividly described by Charles Darwin, and the growth of such specialization in later times has led to many criticisms of its effect upon the human subject.

It is in the schools that we view the education of the incipient scientific worker in its broadest aspect ; and it is here, helped in the ideal case by home influences, that the foundations of the necessary wider interests must be firmly laid. There ought to be no sense of antagonism between arts and science, and any form of modern education should be made up of a proper blend of each. A lively interest in literature, history, art, music or the drama, gained in early life and nurtured thereafter, would do much to solve some of the problems of specialization in science. Highly specialized teaching in science ought to be avoided in the schools.

In the universities, the way of teaching chemistry is of the first importance. Although his chemical studies must deepen rather than broaden as the student passes onwards towards research, he should always be encouraged to realize that there are a chemical geography and a chemical history, and that these offer him avenues leading to a wider horizon. Chemistry itself may become a cultural and humanistic instrument of high value. Historical chemistry is linked in turn with philosophy, literature, art, and even with music. During the student's undergraduate days a great deal could be done to arm him against the dangers of specialization, and more importance should be attached to the technique of teaching from this point of view.

During postgraduate research work the student should be encouraged to undertake a certain amount of teaching work in the junior laboratories. He should also use opportunities to migrate to new research centres either at home or abroad. A research theme of a suitable kind ought to help the student to become resourceful and to develop originality of thought, besides stimulating his imaginative and critical powers ; unfortunately, research themes often fail to fulfil these requirements. Finally, the proper education and training of the young scientific worker, with the application of the various influences that have been mentioned, including personal contact with his teachers, call for the provision of adequate staff and accommodation.

GEOLOGY TO-DAY AND TO-MORROW

THE theme of Dr. A. E. Trueman's presidential address to Section C (Geology) is the future of geology. At the present time, he points out, geology is passing through a period of very active growth. It is doubtful if at any time since the 'heroic age' of the science, a hundred and fifty years ago, there has been so rapid an increase in our knowledge of earth history. More geologists are professionally employed in all parts of the world ; many more fields of human activity are dependent on the success of their operations than ever before. They search for ores, coal, oil and water. If in the future we are to depend on atomic energy for some of our power, it will need geologists to locate the new materials. Inevitably, we shall be driven to exploit mineral resources occurring at greater depths, or of poorer quality ; while we continue to use materials from the earth's crust the geologist will have an increasing part to play in their discovery. In the course of these explorations much new information is being gathered, but many major problems still await solution.

Although geology is in this phase of active development, its results and methods are probably less familiar to the educated public in Britain than those of any of the other fundamental sciences. This widespread unawareness of geology, which is not found in most other countries, is in marked contrast with the position of fifty to a hundred years ago and calls for serious attention, for it cannot be held that any science is in a healthy condition if its work is insufficiently understood by laymen. The absence of almost any geology teaching in schools and the scarcity of teachers with any acquaintance with the subject are partly responsible for present conditions. It is claimed that geology should form part of a wide cultural education ; it can serve as a link between science and more humane studies or as a basis for a new type of synthesis.

Fortunately, the comparative lack of public interest in geology has not in recent years limited the recognition of its value by Government. Much has happened to stimulate the demand for geological advice for a variety of economic purposes, both in Britain and overseas. In the limited area of Great Britain, the Geological Survey, founded more than a hundred years ago, not only meets new demands for more detailed maps but also is required to undertake great new responsibilities. The record of its work in war years, recently published, exemplifies the wide range of activities in which geological information is necessary ; in view of the growing importance of the work of the Survey, the need for an expansion of its numbers has been recognized. The Colonial surveys, even more in need of increased support, are accepted as having a vital part in the economic development of the Colonial territories. The present Secretary of State for the Colonies has himself on several occasions appealed to young men to take up the work of geologists in these areas. The small surveys of the past have been sparsely staffed, one geologist being responsible for thirty times the area for which a member of the home survey was responsible. In the past, several Colonial geological surveys have paid for their own cost many times over by discoveries of diamonds and ores, but future results must not be judged only in terms of exportable minerals ; more bulky materials, such as limestones, clays, road materials and especially water, may contribute even more to the development of the territories. Alongside these developments of geological survey activity throughout the Commonwealth, the promotion of researches by unofficial geologists is equally essential.

In the immediate future we must expect an increasing tendency to specialization in limited fields and particularly on the fringes of the subject, as on the borderlines between geology and physics, or geology and chemistry. Advances in such fields as geophysics call for workers with more extensive training in the two subjects. The co-operation of geophysicist and geologist makes possible the interpretation of concealed structures: England south from the Wash requires special study in view of the possibilities of new coalfields. But on a wider front we may expect to learn more of submarine areas, of the structure and origin of mountains and of the larger features of the earth. Work in geochemistry, in the distribution of minerals, the origin of rocks and the nature of clays, promises rapid development. In the fields of geomorphology the problems are barely touched; in palæontology the existing data only serve to illustrate the extent of the problems to be solved. But in all these extensions of knowledge it may be hoped that it will be possible to avoid the isolation of the fields of study, relating them all to stratigraphy and the study of the structure of the earth's crust which form the 'heart of geology'.

TEACHING ZOOLOGY IN THE UNIVERSITY

PROF. H. GRAHAM CANNON discusses "Undergraduate Zoology" in his presidential address to Section D (Zoology). After the First World War, he says, the interest in zoology became almost exclusively experimental. The more orthodox attitude of comparative anatomy became the one to be avoided. This was due to a variety of reasons, but largely because, for generations, zoologists had been teaching the comparative anatomy of dead animals without worrying about how these animals lived. As a result of this changed outlook between the two World Wars, a generation of teachers has grown up who are predominantly experimentalists, and our present undergraduates run the risk of becoming very knowledgeable about the latest developments of experimental technique while knowing very little indeed about the anatomy of the animals on which they work. Recently, but somewhat tardily, it has become recognized that there is such an aspect of zoology as functional morphology, that is, a method of treatment where structures are dealt with not merely in the way in which they are built, but also, and at the same time, from the way in which they function. It is this attitude which should form the basis of undergraduate zoology.

Two main difficulties present themselves in considering the teaching of zoology to undergraduates. First, there is the modern tendency to scorn any elementary teaching and to thrust the first year's university work back on to the schools. This misguided attitude may be excusable in the more basic physical sciences and mathematics; but in the biological sciences, which, after all, utilize the physical sciences as their tools, it is completely illogical. Moreover, it is essential that the more experienced teachers, preferably the professor, should always deal with this fundamental first year's introduction to university study.

Secondly, there is the tendency almost everywhere to introduce specialist courses into the undergraduate years: a tendency which is being encouraged by the efforts of the University Grants Committee to foster the establishment of readerships or even chairs in the most abstruse specialist aspects of biology. At the undergraduate stage the students are quite unable to assimilate such courses. The sort of courses which are being established are those admirably suited for the second part of the Cambridge Tripos. But what is almost invariably overlooked is that the second part is entirely a postgraduate course. The honours degree is given on the first part of the Tripos, and this corresponds to the degrees in the 'Redbrick Universities' of honours general science. It is suggested that it would be a great advantage in all 'Redbrick Universities' to abolish the specialist honours degree altogether and insist on a first degree being taken in general science as at Cambridge. The more specialist attitude to the subject could then be left to a postgraduate year, leading preferably to a master's degree.

SOCIAL GEOGRAPHY

IN his presidential address to Section E (Geography), Lord Rennell of Rodd deals with the geographical environment of man as a social animal, and consequently does not attempt to consider the geographical circumstances of the origin of human species or prehistoric man. But the spiritual as well as the material consequences of geography on human society are considered rather by posing a series of questions, and stating a number of problems, especially in connexion with Africa, than by proposing conclusions or solutions.

Starting from the influence of geography on the spiritual as well as on the material development of society, Lord Rennell makes a strong plea, which he takes up again at the end of the address, for the teaching of geography in medium and higher education as a means of creating a bridge between the humanities and the natural sciences, which "except among the leaders of the latter group" have more and more tended to develop on independent lines divorced from each other. This tendency he dates from the decline in classical education; but he sees in geography, and especially in social geography, a new link which could be made between the two, in view of the manifold contacts which geography has with both the exact and the abstract realms of human thought.

From this point he goes on to discuss a number of problems arising in Africa. What are the reasons why Islam spread as far as the southern rim of the North African deserts but never affected the population south of the northern fringe of the forest belt? Why was the negro and negroid population of Africa antagonistic to outside civilization in spite of many opportunities of contact with more civilized people from Greek and Carthaginian times through all the period of Arab and Portuguese navigation until the European conquest? Why then, and only then, did a ferment of Western civilization begin, within say the last seventy years? Yet the civilizing influence of the Mediterranean found no difficulty in crossing the Sahara and following up the Niles until they came to a dead end against the unwillingness of the negro to adopt or adapt. Why is there no trace of writing or even ideography in Dark Africa? Why was there no true architecture, the wheel or the plough in Africa south of the deserts until the conquering European started the modern phase?

Lord Rennell goes on to discuss the anomalous and absurd consequences of the European conquest, the purpose of which, in spite of Lord Hailey's investigations, remains very obscure. He refers to the ribbon development of colonies along the coastal routes, and the strange efforts of our Colonial Office to keep separate, contiguous British territories in eastern Africa, in spite of departing substantially in recent years from the dual mandate principle in favour of "colonies d'exploitation". He concludes with the suggestion that only the geographer with a foot in each of the camps tenanted by the humanist and the natural scientist, is fitted to seek answers to the problems he raises, and is unbiased enough to propose solutions which it is incumbent on European nations generally, and ourselves in particular, to find, in order "for the sake of our own good name" to remedy the administrative and social chaos which is Africa.

THE PRICE SYSTEM

IN his presidential address to Section F (Economics), Sir Hubert Henderson remarks that the idea of a return to the price system which is widely advocated to-day is marked by the same defects that marred the idea of economic planning which was so popular a year or two ago, namely, incoherence and wishful thinking.

In its most general sense, the price system is an inevitable outcome of the use of money. So long as goods and services are bought and sold for money, there must be prices; and these prices must always exert a powerful and pervasive influence. It is important, therefore, that this influence should be a healthy one, that the configuration of prices should be such as to pull in directions which accord with the public interest. We want price relations that are right, so far as that object is attainable. But we must be careful not to beg a major question. In the matter of price relations, as in many others, it is easier to be sure that certain things are wrong than to know at all precisely what is right.

According to current price system ideology, the right price is the theoretical equilibrium price. In times of large-scale economic maladjustments, however, this concept is ambiguous. The theory of value comprises two parts, short-term and long-term, each with its appropriate equilibrium price. These prices are seldom far apart in ordinary times, when the economic system has not been subjected to any recent large disturbance. But they are apt to diverge widely when the maladjustments to be corrected are very large. It is a mistake to suppose that in such conditions the theoretical short-term equilibrium price is either what we want, or what we normally get in a free economy. There are apt to be serious and injurious anomalies in price relations when shortages are widespread.

Shortages, or surpluses, are, of course, most widespread, and the consequential anomalies most serious, when there is a large maladjustment between aggregate demand and aggregate supply. It is therefore especially important to avoid disequilibrium here. In Great Britain at the present time it is rightly a main object of policy to remove the inflationary trend in our economy. Success in this might enable us to dispense with many of the controls that irk us to-day, and to simplify others. But it would not enable us to remove them all. The regulation of long-term capital expenditure would still be desirable for a fairly considerable time, and the regulation of imports indispensable for a much longer time.

If the consuming public were free to choose, there is no reason for supposing that imported goods would represent a smaller fraction of their total purchases than before the War. Since our total rate of consumption is at about the pre-war level, this would imply imports at about the pre-war level; or an increase of more than one quarter in our present import-bill. The removal of every vestige of inflation in our internal economy, though helpful, could not radically alter this result. With a huge deficit in our current balance of payments, we are in no position to contemplate a largely increased expenditure on imports.

Price system ideologues believe that disequilibria in the balance of payments can always be corrected by variations in foreign exchange-rates. This belief is attributable to the pivotal role which they assign to the concept of equilibrium price. When, however, our import–export balance is so far from adjustment, there is a huge divergence between the short-term equilibrium rates of exchange and the long-term norm represented by purchasing-power parity. It might be disastrous to try to make our actual exchange-rates approximate to the former. It is better to keep them in the neighbourhood of purchasing-power parity; and to recognize that it will remain essential to regulate the volume of our import purchases as effectively as we now do by means of import restrictions.

More generally, the time-honoured theory of value endorses, and indeed enjoins, the humdrum practical proposition that, when large adjustments have to be made, regulation and deliberate direction may be useful or even indispensable.

THE YOUNG ENGINEER

IN the presidential address to Section G (Engineering), Wing-Commander T. R. Cave-Browne-Cave deals with the qualifications and personal qualities necessary in 'the young engineer', and treats the problem of engineering education from an unusual point of view because his experience has been in the application of engineering science to a wide variety of new developments, mainly in connexion with airships and aircraft engines. Since going to University College, Southampton, he has been dealing not only with students preparing for the external degree of the University of London, but also with apprentices following part-time courses for national certificates and still more practical qualifications. The review is based upon the knowledge and personal qualities which a young engineer should have acquired shortly after the end of his formal training, say at the age of twenty-eight to thirty, and may serve as a guide to those who are considering engineering as a career. It may also be taken as a background against which the various stages of engineering education are examined.

Mathematics is a limiting factor in the progress of a student along the main road of engineering science. It must, therefore, be of a really appropriate type and no harder than is necessary for each corresponding stage.

The general structure of engineering education should be revised so that it is possible for candidates to enter at any appropriate stage. Changes from one course to a more suitable one should be simpler than at present, and there must be fewer 'casualties' who fall out and go no further. Courses of instruction should be aimed, not at a final examination, but at the future useful application of the knowledge acquired.

The student must develop the art of learning by himself from books, because he will have to acquire in this way a great deal more science and technology than can be included in his formal training. If this is achieved, the present overcrowded syllabuses can be shortened by leaving certain parts for subsequent study when required.

Attention is directed to the importance of developing skill in clear explanation of technical matters, both in verbal discussion and in writing. The effective value of a proposal depends not only upon its technical merit but also upon the clarity with which it is communicated.

It is suggested that national service for students who are to read for a degree should be taken between the intermediate examination and Part I of the final degree examination, and that the fighting services should arrange this year to give, in addition to military training, a good practical groundwork similar to that given in the first year of service technical training. The year of national service would then be a valuable addition to the degree course as well as a foundation for future war service, if required.

Personal qualities, judgment, effectiveness, enterprise and determination are so important that they must be considered in the selection of a candidate and must be developed throughout his training.

The address is intended to open a general discussion on engineering education, relating it definitely to the knowledge and qualities which experience shows to be desirable in later engineering work. It contains much new and possibly contentious matter, which, with the discussion on it, should form a useful contribution to the developments which now have to be made in engineering education at all levels.

INVESTIGATION OF FOLK-LIFE IN BRITAIN AND ABROAD

MR. R. U. SAYCE discusses folk-life in his presidential address to Section H (Anthropology). Until about 1914, Britain occupied a well-recognized place in the front rank of folk studies; but since that time it has been falling further and further behind, and appears to a great extent to have lost touch with the developments that have taken place in European countries. A few scholars continue to produce work of distinction; but they lack a common meeting ground, where adequate discussion can stimulate thought and help them to see their special problems in relation to the whole. There are even societies devoted to dialects and place-names, beliefs and customs, dance and song, which have scarcely any contact with one another, although they are all concerned with the culture of the folk. In spite of this fragmentation, we are realizing, as general ethnologists have already done, that a culture must be studied as a whole. This, of course, makes our studies more complex, but also far more interesting. It also needs special training; the student of folk-life must know something of the methods of, and the results achieved by, archæology, history, psychology, anthropology, to say nothing about architecture, agriculture, technology, etc. There can be little doubt that the present unsatisfactory state of British studies in this field is due largely to the failure of the universities to provide the necessary training.

Folk-culture is very closely related to ethnology and to history, and could only neglect one of these indispensable allies at great loss to itself. For many years it has enjoyed close contact with ethnology, to which it is greatly indebted; but it has neglected its second essential partner, so much so that it has been in danger of becoming an unimportant appendage of the former. Nevertheless, a very slight knowledge of our problems is sufficient to make it clear that their solution depends on a historical approach. The subject does not consist of an inert mass of survivals from a vague and generalized past. The contents and their vitality change. Sometimes customs and beliefs appear to survive only in remote circles or among the least educated, and these periods may be succeeded by others when irrational ideas spread rapidly and become widely current. We can see fluctuations of this kind in western European civilization as well as in that of ancient Greece.

The impression must not be given that folk-culture deals only with 'primitive thought' and superstition; it includes the whole way of life of the people—their houses, clothes, food, work, and recreations. All these change, sometimes abruptly, at other times almost imperceptibly; old elements drop out, and new ones come in. For a knowledge of the changes we have to turn to a much closer co-operation with historians and archæologists.

At the present time, certain long-established interpretations of European folk customs are being challenged. A new school of folklorists questions whether the old harvest customs, for example, had any connexion with beliefs in vegetation spirits, and suggests that scholars like Maunhardt and Frazer made insufficient allowance for the spirit of jollity and of competition that would be quite natural where young men and women are for the time working together in the fields. The new school recommends a more modern, functional approach to the problems. There is very much of interest in their arguments, but the question is essentially a historical one. What did the medieval peasant think about the powers that influenced growth and fertility? Did he hold animistic beliefs, or was the hare that dashed out of the last standing corn nothing more than a hare? Until we can answer such questions, it would be as dangerous to apply ideas derived from studies of harvesters during the last century or two to their forerunners of a thousand or two thousand years ago as it would be to accept a modern educated African as a guide to the conceptions and emotions that underlie the age-old tribal customs.

In conclusion, Mr. Sayce makes a strong appeal for properly trained workers in Britain, and for the fullest possible intercourse with scholars in those countries where studies of folk-life have made so much more progress in recent years than they have done in Great Britain.

RECENT ADVANCES IN COLOUR VISION

IN his presidential address to Section I (Physiology), Prof. H. Hartridge discusses recent views on the mechanism of colour vision. Colour vision to-day, he says, is in a situation not very different from that of nutrition half a century ago. The solid constituents of the diet—the proteins, the fats and the carbohydrates—were well known and understood. All major problems concerning them had been solved and there was really little more to be found out about them. Then suddenly the importance of the accessory food factors, the vitamins, began to be disclosed. Substances, small in amount, became of prime importance in dietetics, and we know to-day how much our health and well-being depend on these accessory food substances.

Atomic physics might be taken as a second example of a branch of science where not many years ago all problems appeared to have been solved and everything to be known. We have only to look back at the last thirty years to realize how very limited our outlook really was in those days.

Human colour perception to-day is in a similar situation, because, until quite recently, most—if not all—known visual phenomena were adequately accounted for either on the three-colour theory of Thomas Young or on the four-colour theory of Ewald Hering. But we are beginning to suspect that things are not quite so simple as they seemed and that there may be present in the human retina certain accessory receptor mechanisms, not embraced by either of these theories, which, however, play an important part in man's colour sense. The questions which now confront us are similar to those which claimed the attention of the early workers on the vitamins.

So far as present evidence goes, there appear to be four additional types of receptor, three of which have a single maximum of activity in the spectrum, which is situated in the yellow, in the blue-green or in the blue. The fourth has two regions of activity: in the extreme red and in the extreme violet; and for this reason may be referred to as 'the crimson receptor' mechanism. These four accessory mechanisms, which play a relatively unimportant part in foveal vision at medium visual angles and at medium light intensities, hold a very different position when these conditions are departed from. Thus in the dichromatic zone of the retinal periphery, at medium light intensities and at the fovea at very high intensities, two of these subsidiary receptor systems, the yellow and the blue, hold a predominant position. On the other hand, at very low light intensities and at very small visual angles, the two receptor types which are most strongly represented are the crimson and the blue-green.

While nearly every phase of human colour perception, when closely examined, discloses evidence of the presence of these supplementary receptors, the idea that there are four of them, or that they have the properties preliminarily assigned to them, may have to be modified in important respects as additional knowledge is acquired.

Lessons of a valuable kind are to be learned from a study of the history of the vitamins; because, whereas only a few years ago a few appeared to suffice, we now have overwhelming evidence that there are many. So it may be with the visual receptors. At this juncture the important point is for us to recognize that accessory receptors are present in the human retina, and then to concentrate attention on the wider problems which their presence involves.

PRESENT-DAY TRENDS IN BRITISH PSYCHOLOGY

PROF. REX KNIGHT, in his presidential address to Section J, remarks that more than sixty years have now passed since the "Encyclopædia Britannica" first published in 1886 Ward's famous article on "Psychology", which William James at once described as "marking the transition of British psychology from one epoch to another". Ward's article showed that psychology was no longer to be regarded as a branch of analytic or speculative philosophy, but as a positive science concerned with the systematic investigation of matters of fact. Since it appeared, striking changes have occurred in the scope, methods and practical usefulness of psychology in Great Britain.

In scope, there have been five major developments. First, physiological psychology, which everyone except Bain neglected in the 'eighties, has come into its own. This has been due to the advocacy of Sully and James, the general acceptance of the evolutionary theory, the researches of neurologists like Lashley and Sherrington, and the influence of the behaviourists.

Secondly, psychology is no longer preoccupied with cognition. The work of James, McDougall and Freud has developed an intense interest in dynamic psychology, and at least as much attention is now given to the conscious and unconscious motives that underlie thought and behaviour as to the processes which are involved in the acquisition of knowledge itself.

Thirdly, sixty years ago psychologists concerned themselves mainly with human beings, and with human beings who were adult, civilized and normal. Now animal psychology, child psychology, anthropological psychology and abnormal psychology are all prominent features of the psychological landscape, and are receiving much attention.

Fourthly, psychology was generally regarded in 1886 as the study of man as an isolated individual, whereas present-day psychology is much concerned with man as a member of society.

Fifthly, the last sixty years have seen the development of mental tests, which, though originated by Galton before Ward's article appeared in the "Encyclopædia Britannica", have been developed during the present century in Britain chiefly by Spearman, Thomson and Burt.

In method, there have also been five notable changes. First, introspection, which dominated the field in 1886, has been supplemented by observation of behaviour and exploration of the unconscious. Secondly, experimental psychology, which was disparaged by most nineteenth-century British psychologists, has established itself. Thirdly, the anecdotal method, once so common in psychology as well as biology, is under sentence of banishment. Fourthly, field-studies have become as important as laboratory investigations. Fifthly, the statistical principles and techniques appropriate to psychological data have received great attention.

In practical usefulness, psychology in Britain has moved during the period under review from a stage where applied psychology was almost unknown to one where psychology is constantly being applied to the practical problems of public and private life. Educational psychology is now an important ingredient in the training of teachers, and educational psychologists are becoming established members of the staffs of education authorities. Psychiatry is a recognized branch of medicine, and clinical psychologists are employed in many fields. Occupational or industrial psychology, the development of which in Great Britain owed so much to Charles Myers, was used on a large scale in the Second World War, and is now being used in the drive for greater productivity.

STUDY OF THE BRITISH FLORA

IN his presidential address to Section K, Prof. J. R. Matthews begins by referring to some of the more noteworthy landmarks in the history of British botany. The exact recording of native plants, an essential preliminary to the formulation of any scientific account of them, dates from the time of William Turner. Although new records have continued to be made down to the present time, the discovery and discrimination of more than a thousand species of vascular plants before the death of John Ray in 1705 remains an outstanding tribute to the work of the early explorers. Much of the subsequent floristic work was carried out by botanists who made no claim to be called professional, and it often found expression in the publication of local or county floras. The value of these surveys could not be seriously doubted, and there is a growing need for their encouragement and support by all responsible authorities, public or private, who have the desire to see a revival of interest in the scientific study of local natural history.

The edifice of British botany raised by the early naturalists gradually became expanded and enlarged, and by the end of the nineteenth century, knowledge of the composition of the native flora was relatively complete. The distribution of plants had also attracted considerable attention, and Great Britain had become one of the best botanically explored countries in the world. But along with other subjects, botany shared in the general scientific renaissance which occurred in the early years of the twentieth century. Although the systematic study and recording of plants continued, greater emphasis began to be laid on the ecological approach to field studies. The investigation of heredity and the study of variation by the experimental method and the advance of cytology were at once recognized as sources of valuable data contributing towards an understanding of the species problem, which had followed the enunciation of the Darwinian theory of evolution. Detailed ecological studies of individual species throughout the range of distribution were necessary, if the responses to changing environmental conditions were to be correctly interpreted. Such investigations were closely connected with problems of taxonomy, since it was evident that much intraspecific variation was related to environmental gradients. It should therefore become the purpose of experimental taxonomy to examine and analyse the heterogeneous nature of the species complex and correlate the results of such analysis with those derived from physiological and ecological studies. Investigations along these lines would prove of immense value in the application of scientific botany to the practice of horticulture, agriculture and forestry.

THE SCHOOL IN A PROGRESSIVE SOCIETY

IN his presidential address to Section L (Education), Mr. W. O. Lester Smith points out that school business has increased rapidly in recent years, affecting each of the leading partners in educational administration—the Ministry of Education, the local authority, the head teacher and his colleagues. It is worth considering how this has come about, and there would seem to be three main causes: social change, the widening scope of education, and the modern emphasis on management. The administrative pressure on the head teacher is more serious in its consequences than that on the other two partners, because hitherto in Great Britain we have regarded the school as the natural growing point of educational thought and technique, and we owe much to the creative wisdom of some of our great head teachers.

It is usual to attribute the increase of administration to the growing demands of Government departments; but this is a partial diagnosis, for the preoccupation of the head teacher with managerial detail began not in the schools associated with the State but in the independent public schools from the days of Thring onwards. It was due largely to the emphasis in these schools on an active corporate life and on giving each pupil a full or 'total' education. In a sense, therefore, the criticized Rugby appointment of an administrator as head master was but a logical recognition of a process that has been unfolding itself for a century.

The head teachers of the primary and secondary schools associated with the State in Britain are now being diverted from their educational task by a growing administrative pressure, and this is particularly unfortunate because the abolition of the elementary school by the Butler Act was a historic opportunity; and the heads of the schools emerging from the elementary tradition ought to be free to concentrate on the difficult task of making education a living force in the social democracy now taking shape. Just when imaginative leadership is urgently necessary, the head teacher's function is becoming increasingly managerial as a result of the growth of corporate activities, the demands of society, and the aftermath of Government schemes and schemes launched by well-meaning importunate organisations.

Some of the new demands are necessary and desirable, but others are hard to justify. There is also an increasing use of schools for extraneous purposes, involving the necessity of putting away daily all equipment and appurtenances of educational or æsthetic value. We cannot hope to achieve quality unless we are prepared to put education first; and it is regrettable that, owing to shortages of staff and buildings, we make a habit of measuring progress in quantitative terms. The schools of the people were for centuries retarded by what Defoe called the law of subordination, and to-day Demos is apt to treat his schools like the old feudalism writ large.

One of the most difficult issues is to determine the extent to which schools should respond to the many claims which society makes upon them. There is general agreement that they cannot to-day thrive in isolation, or, as the McNair Report puts it, teachers cannot be "a race apart". On the other hand, there is a limit to sociability, a plimsoll line at which service to the community becomes a danger to education. If a service rendered by a school fits naturally into the curriculum or the corporate life, it may provide useful educative experience; but if there is a marriage of convenience designed primarily to further an extraneous scheme, there can be serious waste of teacher- and pupil-time without compensating advantage. We ought, as a nation, to recognize before it is too late that the essential function of each school is to educate, and that of each head teacher to give expert guidance to his team in the conduct of an extremely difficult operation, requiring human sympathy and a sure grasp of the intricate problems of childhood and adolescence.

AGRICULTURE AND THE WORLD FOOD PROBLEM

IN his presidential address to Section M (Agriculture), Dr. G. Scott Robertson compares the present world food problem with that in 1798 when Malthus put forward his theory that populations tend to outrun their means of subsistence. The invention of machinery, the discovery of artificial fertilizers, the development of transport and colonization for a time made his views seem unduly pessimistic and out of date, but two world wars have brought up afresh the problem of attempting to provide adequate food for the peoples of the world.

The two chief factors responsible for the present situation are the rapid increase in the world's population (estimated at 20 million per annum) and the improved standard of living of that population. Fortunately, the prospects of finding a solution are more hopeful to-day than they were a hundred and fifty years ago, when hand labour and primitive tools set a limit to agricultural production, for by merely applying existing knowledge and making a fuller use of available resources, the world output could be doubled or trebled in a relatively short time. The Food and Agriculture Organisation is doing valuable work in pointing the way by which this can be done, and the only permanent solution seems to be in increasing production in each country. The requirements of India and China, for example, are so vast that outside help would be inadequate even if it could be provided and the immense transport difficulties overcome.

Aid from the more advanced countries can best be given by helping the less developed ones to modernize their agriculture so that they can feed their own peoples. To do this, very large quantities of fertilizers will be required, and fertilizer manufacture must form a part of their industrialization. Even in Europe and America, much could be done to improve output. More attention to the growing and conservation of grass, for example, would increase milk and meat production and at the same time reduce the competition with the human population for cereals. Enormous economies in grain crops could also be achieved if the ravages of pests during storage were prevented; the knowledge exists and only the practical application of it is needed. The Council of the Food and Agriculture Organisation has already taken this matter up and recommended member countries to take immediate and concerted action in such matters.

Losses in the animal world from disease are estimated as even more serious than in the case of crops, and the necessity for preventing this wastage becomes the more vital as the standard of living rises not only in advanced countries but also in the more primitive.

Improved nutritional standards will inevitably mean changes, for agricultural produce will have to play a more important part in world trade than in the past, and the old conception of exchanging agricultural for industrial products gradually give place to an interchange of agricultural products. Restrictions, such as tariffs and quotas, will have to disappear, for no country should be forced into a form of agriculture unsuited to its soil and climatic conditions. The peoples of the world, in fact, will not be properly fed or any real prosperity achieved until there is both a greatly increased output and the fullest interchange of the products of agriculture on a world-wide scale.

THE CORRESPONDING SOCIETIES AND THE COMMUNITY

THE president of the Conference of Delegates of Corresponding Societies, Prof. H. J. Fleure, deals in his address with the relationship between the corresponding societies and the community. Many such societies belong to and have opportunities to serve our cities and counties in the important and necessary effort to re-emphasize social life, which has been submerged by the crowds that have taken the place of traditional groups, crowds made up of atomized individuals. Rousseau, Hobbes and others have too often spoken as though human society were made by the coming-together of individuals, whereas it is in society, itself basically a heritage from pre-human phases, that human individuality has struggled towards expression. The group again and again has sought order through imposed uniformity; the individual has, increasingly, rebelled and has immensely extended men's vision. We need only read anything written about man and the universe before Copernicus, Bruno, Galileo, Newton and Darwin to realize the importance of the newer ideal "We seek the truth"; imposed uniformity may prevail for a short time, but it must fade; it closes the mind.

In the late eighteenth century steam-power and mass-production set society sailing on an uncharted sea and found it philosophers to justify or excuse exploitation under the theory of *laisser-faire*. The atomization of the individual, the submergence of society in the crowd, have been widespread with unfortunate consequences. The corresponding societies and the British Association, both pledged to the search for truth, can help one another and our communities towards rehabilitation. The local society can help and advise planners in their work of adjusting the environment and can bring wisdom from the past without, one hopes, imposing that as a dead weight on the future.

The Education Act, 1944, assigns 'secondary' status to many schools hitherto primary, and in these the education, for the less bookish, must be to a considerable extent visual. Members of local societies can help in the schools to spread knowledge of the locality, can guide school parties, promote local museums of folklife, publish books and booklets that will help teachers and pupils to understand their locality; and the British Association can help with advice on such work; it could also organise short conferences in many towns and cities which cannot quite manage the full annual conference, sending delegates specially chosen because of the help they can give. Contacts spread over a few days and extending into the field as well as the lecture room can be more vitalizing and have a more enduring effect than visits of a lecturer for one evening's meeting.

Co-operative research on land utilization, on interpretation of Domesday and other historical surveys, on local names and implements, land tenures and field systems can all be made to help rehabilitate social life. Much of this work can find expression not only in the transactions of local societies, but also in local museums made intelligible to the public, in improved education with partnership between the societies and the teachers and pupils, as well as in scientific contributions to a National Atlas of Britain, a new survey of land utilization and many other efforts of both planners and historical and scientific searchers.

NEWS and VIEWS

Death of President Beneš

By the passing of Dr. Eduard Beneš on September 3 at the age of sixty-four, Czechoslovakia loses its former president, and the world loses a cultured and learned man who had striven for the welfare of all mankind during the past forty years. Born in the Bohemian village of Kožlany on May 28, 1884, Beneš studied philosophy, philology and sociology at Prague and later at Dijon, where his thesis was "Le problème autrichien et la question tchèque". Beneš then spent a short time in London and Berlin before returning to Prague, where he attracted T. G. Masaryk's attention. In 1915 Beneš escaped to Geneva, and with Masaryk and Štefánik (a Slovak astronomer who became an air force general and Czechoslovak War Minister) organised Czech resistance to the Central Powers. Beneš became Czechoslovak Foreign Minister of the first provisional Government, and after the republic was established in October 1918, he retained that post in successive administrations until he succeeded Masaryk as president in 1935. His work became more arduous with the rise of Nazism in Germany, and Beneš had soon to face another exile. Returning in 1945 as president of liberated Czechoslovakia, he was confronted with greater problems than before, since war and occupation had brought more distress than the First World War.. The strain of post-war anxieties, the events of February last and Jan Masaryk's suicide, deeply affected him. President Beneš, who had always maintained an interest in learning and culture (especially in the social sciences) made his last public speech on April 7, at the sexcentenary celebrations of the University of Prague (see *Nature*, May 1, p. 670). Among the exhibits in connexion with these celebrations were several items associated with Benes' academic life, including the original Dijon thesis. Since February, President and Mme. Beneš had lived in their country house at Ústí Sezimovo in south Bohemia and had taken no part in public affairs, although he did not resign from the presidency until June 7. Like the Masaryks, Beneš was a 'great European' with wide vision, and though his work for greater understanding among peoples seems recently to have been in vain, he has shown mankind the way.

Presentation to Sir John Parsons, C.B.E., F.R.S.

At a ceremony held in the Royal College of Surgeons on September 3, Sir John Parsons was presented with his portrait in oils, painted by Mr. John Gilroy. The presentation was made by Sir Stewart Duke-Elder, in the name of the members of the Faculty of Ophthalmologists and the Ophthalmological Society, and to mark the celebration of Sir John's eightieth birthday. It is good that Sir John's long and strenuous career has met with such a fitting and happy culmination, for he has long been the acknowledged leader in all aspects of British ophthalmology—clinical work, basic research and public activities. For more than a generation he has been the recognized leader in the clinical practice of this specialty, and opthalmologists of a much wider circle than Great Britain to-day treat their patients better because of his precepts and his writings. So long as ophthalmology is a science, his name will be remembered for the work he did fifty years ago as a pioneer in ophthalmic pathology. To-day he is still the foremost authority in the fundamental sciences concerning vision—biological, physiological and psychological. In guiding, stimulating and encouraging ophthalmic research he has in his time stood out almost alone. In all problems concerning vision successive Governments and industry have asked and received his help; he served in the two World Wars, in the First as consultant to the Army, in the Second as adviser to the Royal Air Force; in international ophthalmology he has consistently been an acceptable and gracious British ambassador; and for years he was the dominant figure in the social and political life of the ophthalmologists of Britain.

Probably, however, the greatest contribution which Sir John Parsons has made is the historical continuity he has succeeded in maintaining between the past and the future. In his youth, ophthalmology in Britain was great among the nations; but later—largely because with the evolution of science, individual effort had to give place to organised effort for which we were not prepared or equipped—ophthalmology undoubtedly lost its place in Britain. He was largely responsible for reinvigorating it to what may be a future as great as or greater than its past. To-day those who have eyes to see may discern the beginnings of the fruits of his labours. Thirty years ago he was responsible for interesting the Medical Research Council in ophthalmological problems, and to-day these are fully consolidated. Twenty years ago he endeavoured to bring about an amalgamation of London hospitals and inaugurate a research institute; to-day, that is an accomplished fact. He was primarily responsible for the inauguration of the Faculty of Ophthalmologists, and to-day it is growing lustily. To him and to all of us these promising developments of his ambitions ought to be a source of satisfaction.

Physiology at the London Hospital

Prof. D. T. Harris

Prof. D. T. Harris, on whom the title of professor emeritus has been conferred by the University of London, is to retire at the end of the present session from the chair of physiology which he has held at the London Hospital for the past sixteen years. Prof. Harris studied physics as a special subject at Cardiff, where he took his B.Sc. in 1904. He graduated in medicine at Manchester in 1914 and after holding various hospital appointments and experiencing general practice served as a temporary captain in the R.A.M.C. After a short period as lecturer in physiology at Manchester under Prof. William Stirling, he joined the Institute of Physiology at University College, London, where he held a Beit Memorial Research Fellowship and as Sharpey Research Scholar came under the influence of Sir William Baylis and Prof. E. H. Starling. He obtained the D.Sc. London in 1926 and held the post of assistant professor of physiology in University College, London, when he was appointed to the chair at the London Hospital in 1932. Throughout his academic career Prof. Harris has maintained his interest in physics, his scientific work being mainly concerned with problems arising in the territory bridging physics and physiology, and in particular with the biological action of ultra-violet radiations and ultra-short waves. His contributions to knowledge of these subjects have been published in a series of papers in the *Journals of Physiology, Biochemistry* and *Scientific Instruments*, and his textbook on "Ultra-Violet Radiation" is widely used by operators of ultra-violet lamps who wish to study underlying principles and methods of measurement. In another direction he applied his knowledge of physics to his hobby—photography—and this brought him in contact with the scientific research workers in the cinematograph industry, to whom he gave a series of lectures on stereoscopy.

In the immediate post-war period of intensified university education of 1919–22, Prof. Harris found full scope for his exceptional and natural aptitude for teaching. Large numbers of medical students, and in particular the ex-Service group who came back to complete their medical studies under a sense of urgency to make up for lost time, have cause to be grateful to him for the personal interest he took in their problems and for the systematic clarity of exposition which characterized his lectures and the practical courses he gave for the examinations of the University of London and the Royal Colleges. His book on experimental physiology is used by students in many parts of the world. As a teacher and examiner, Prof. Harris has played a notable part in medical education during the past thirty years, and his many friends will be gratified to learn that, even after his retirement from the London Hospital, he will actively participate in the developments in the teaching of physiology sponsored by the Royal College of Surgeons.

Agricultural Research Council: Lord Rothschild

THE Committee of the Privy Council for Agricultural Research has appointed Lord Rothschild to be chairman of the Agricultural Research Council in succession to Lord De La Warr. Lord Rothschild was born in 1910 and was educated at Harrow and Trinity College, Cambridge, of which he was a fellow during 1935–39. He served in the Army Intelligence Corps during the War and was awarded the George Medal in 1944; was mentioned in dispatches and received the American Bronze Star and Legion of Merit. Lord Rothschild is a biologist, who has carried out research work in the Department of Zoology at Cambridge and has published a number of scientific papers; he has also agricultural interests. He is a member of the boards of the British Overseas Airways Corporation and the Overseas Food Corporation.

Central African Scientific Liaison Office: Mr. R. McChlery

ON September 1, the Central African Council established, on behalf of the Governments of Southern Rhodesia, Northern Rhodesia and Nyasaland, a Central African Scientific Liaison Office in the British Commonwealth of Nations Scientific Offices, Kingsway, London. This arrangement whereby three Colonies, acting jointly, follow the lead of the Dominions by appointing a scientific liaison officer to London provides an interesting new phase in the developing pattern of Commonwealth scientific relations. Mr. R. McChlery, who becomes the first Central African scientific liaison officer in London, went from school at Salisbury, Southern Rhodesia, to take a science degree at Rhodes University College, Grahamstown. He was then awarded a Rhodes Scholarship and proceeded to Exeter College, Oxford, where he obtained the B.A. degree in chemistry in 1925 and the B.Sc. degree in 1926. Following a short course of study at Rothamsted Agricultural Research Station he returned to Southern Rhodesia to join the Chemistry Branch of the Department of Agriculture, where he has since been employed, mainly on problems connected with soil fertility and crop production.

Oxford Science

Oxford Science makes a welcome reappearance after an absence of nearly nine years. Under the general editorship of F. A. Holland, it gives a survey of scientific development in the University of Oxford and is particularly designed to keep the person with a scientific education informed of the progress made in fields of science other than his own. Articles in the present issue (2, No. 1, June 1948) are by A. J. Birch and D. K. C. MacDonald on metal-ammonia solutions; C. J. Dickenson on functional organisation within the cell; J. D. Dunitz and S. C. Wallwork on some developments in structural chemistry; A. H. Cooke on magnetism at low temperatures, and H. M. Sinclair on nutritional science. In the editorial, reference is made to the part played by Oxford men of science in the nation's war effort, to the new laboratories under construction or about to be constructed, and to the closing down of the last of the college laboratories, so that laboratory teaching is now entirely in the hands of the University staffs. Only brief mention is made of the important physical work done in the new Clarendon Laboratory; but a fuller report can be found in *Oxford*, **9**, No. 2, p. 54 (1946–47). Those interested in the progress of chemistry at Oxford may like to refer to the article by F. M. Brewer in *Oxford*, **9**, No. 3, p. 98 (1948), which is very informative.

United States Book Exchange

A BUREAU for the international exchange of books and periodicals between libraries, scientific and educational institutions of the United States and other countries has been opened in the Library of Congress, Washington, D.C. The organisation, known as the United States Book Exchange, is a successor to the American Book Centre for War Devastated Libraries, Inc., and the executive director is Miss Alice D. Ball, formerly acting director of the Book Centre. While the new organisation will continue the rehabilitation programme of the Book Centre, libraries of foreign countries are expected to become members of the new Book Exchange and contribute material to the programme as well as draw from it. During the past two and a half years, more than 1,250,000 volumes have been sent out by the Book Centre, to war-devastated libraries in thirty-one countries. At first the activities of the Book Exchange are being limited to printed matter of scientific or literary character; this will include books, pamphlets, periodicals, government documents, music, printed leaflets, and occasional papers. At present no microfilm and microprint will be dealt with, and no motion pictures, art reproductions and newspapers; but it is hoped eventually to handle all types of printed and filmed material.

Mitigation of Spray Injury

IT is an essential prerequisite of a fungicidal spray that it should not itself cause damage on the plants to which it is applied. This is, unfortunately, not always the case, for lime-sulphur sometimes causes early leaf-drop on the apples Cox's Orange Pippin and Worcester Pearmain. M. H. Moore has shown (*J. Pom. and Hort. Sci.*, **23**, 3 and 4, Dec. 1947) that this damage can be greatly reduced by adding 4 lb. of ferrous sulphate crystals to every gallon of lime-sulphur concentrate before dilution. Sprays against apple scab were made according to the usual schedule. The relative effects of calcium arsenate and lead arsenate separately mixed with lime sulphur as post-blossom sprays were also estimated. Calcium arsenate powder proved more toxic to the apple leaves than lead arsenate paste of much less arsenic oxide equivalent. The inclusion of ferrous sulphate in the mixtures, however, reduced the leaf-drop; but did not markedly prevent fruit-drop. Zinc sulphate provided no suitable alternative to ferrous sulphate; it was highly phytotoxic.

Parallelism between Atomic and Planetary Properties

A SHORT article with the above title in *Nature* of May 15, p. 780, directed attention to the formulation by M. F. Prunier of a wave equation for astronomical planetary systems similar to Schrödinger's equation for atomic systems. It has just been brought to our notice that a somewhat similar hypothesis had been put forward earlier by Mr. B. Liebowitz, of New York (*Phys. Rev.*, **66**, 343; 1944). His equation is satisfied by a variable which he calls the "probability of presence". The subsequent development, very surprisingly, seems to show that for a purely classical problem concerning the planets, akin to Bode's law, using purely classical arguments, an equation can be obtained which has the same form and meaning as Schrödinger's essential non-classical equation. But, in sharp opposition to the conclusion of M. Prunier, Mr. Liebowitz says that there is no implication of a magnetic moment associated with the angular momentum. It will be recalled that the possibility of such a relation, particularly for the earth's magnetism, has been much discussed since Prof. Blackett's article in *Nature* (**159**, 658; 1947) was published.

The Coco-nut Research Scheme

THE annual report for 1944 of the Coco-nut Research Scheme (Government Record Office, Colombo, Ceylon, 40 cents, 20 pp., Jan., 1948) shows that in addition to many routine analyses of copra and coco-nut products, a more detailed examination of the dry distillation of coco-nut shells has been made. The yield of pyroligneous acid was 38·2 per cent and of settled tar, 5·6 per cent. Total acid (as acetic) accounted for 11·6 per cent of the pyroligneous acid, which also contained about 3 per cent of wood spirit. An attempt to use coco-nut shells as a starting material for the preparation of furfurol gave rather poor yields. Manurial experiments with nitrogen, phosphorus and potash indicate that only the potash increased the yield of copra, beginning at the fourth year from commencement of applications. On poor soils, complete manuring with all three major nutrients gave a marked increase in the number of female flowers. Various other experiments on cultivation are also described in the report.

The Royal Anthropological Institute

THE report of the Council of the Royal Anthropological Institute for July, 1947–June, 1948 has appeared. It is pleasing to gather that real progress has been made in all directions. The Institute has always been handicapped through lack of means and in other ways. Though these disabilities have by no means all been overcome, improvement can be clearly noted. The membership is rising, and the library is now in better order. Much activity has been shown in many directions. The Institute fulfils an important function in a country like Great Britain which lies at the centre of a great Empire, and every effort should be made to help it to do what it alone can accomplish for the study and understanding of the many primitive peoples it is still our lot to sustain.

Erdoel und Kohle

THE former German oil journal, *Oel und Kohle*, has now appeared under the title *Erdoel und Kohle* (von Hernhaussen, Hamburg; annual subscription, 60 marks). The first issue of 56 pages was brought out by Dr. Karl Zerbe in June. Its contents cover the future problems of petroleum geology and geophysics and the possibilities of applying secondary recovery methods. In the refining section there are articles on the progress of hydrocarbon synthesis and dewaxing. Scientific abstracts and short commercial notices are included. This journal is the official organ of several technical associations.

Seventh Pacific Science Congress

THE Seventh Pacific Science Congress will be held in Auckland and Christchurch, New Zealand, under the auspices of the Royal Society of New Zealand, and with the assistance of the Government of New Zealand, during February 2–22, 1949. As in previous Congresses, members will be classified as official members (delegates representing the constituent countries of the Pacific Science Association and specially invited guests), members (accredited by scientific bodies) and participants. The Congress will be organised in ten divisions, and within divisions there will be a varying number of sections. The programme is arranged in the form of symposia for the discussion of topics of wider interest for the Pacific peoples; within divisions, subjects of specialist or technical interest will be presented at section meetings. Among the subjects for symposia are: structure of the Pacific basin; Antarctic and Pacific meteorology; oceanography and fisheries of the Pacific; biogeographical provinces; soil resources; ethnographic studies in Micronesia; medical and nutritional problems of the Pacific area. The president of the Congress is Mr. R. A. Falla, president of the Royal Society of New Zealand and director of the Dominion Museum, Wellington; the secretary-general is Mr. Gilbert Archey, director of the Auckland Institute and Museum, Auckland, S.E.1, to whom all communications should be addressed.

Announcements

THE Queen has been graciously pleased to accord her patronage to the Royal Society of Edinburgh, of which H.M. the King is patron.

AT the National Gallery, London, Mr. Martin Davies, who is chiefly in charge of the library, and Mr. Ian Rawlins, scientific adviser, have been appointed deputy keepers.

MR. J. V. CONNOLLY, who has served since 1937 at the Air Ministry, Ministry of Aircraft Production and Ministry of Supply, recently as assistant director of aircraft production, has been appointed professor of aircraft economics and production at the College of Aeronautics.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications

Creep of Metals and Recrystallization

THERE has been a certain amount of dispute as to the fundamental laws of creep of polycrystalline metals[1]. I have advanced the view that the normal creep of a rod extending longitudinally under constant stress can always be represented fairly closely by the formula

$$l = l_0(1 + \beta t^{1/3})e^{kt},$$

where l is the length at time t, l_0 is approximately the initial length and β and k are constants. This gives a final rate of extension per unit length which tends to become approximately constant. On the other hand, it has been contended that there is a final state of accelerated creep, called[2] by some metallurgists Stage 4. When the total extension is of some per cent, this stage is often obtained in tests at constant load and can then, on my view, be attributed to increasing stress, consequent upon the thinning of the specimen. As argument against this, it has been pointed out that the increasing rate of creep has been obtained with extensions of less than 1 per cent in the case of certain steels at high temperature (see Fig. 1)[3]. This I have, however, attributed to recrystallization during the process of creep, recrystallization having been shown to produce increased rate of flow in certain cases[4].

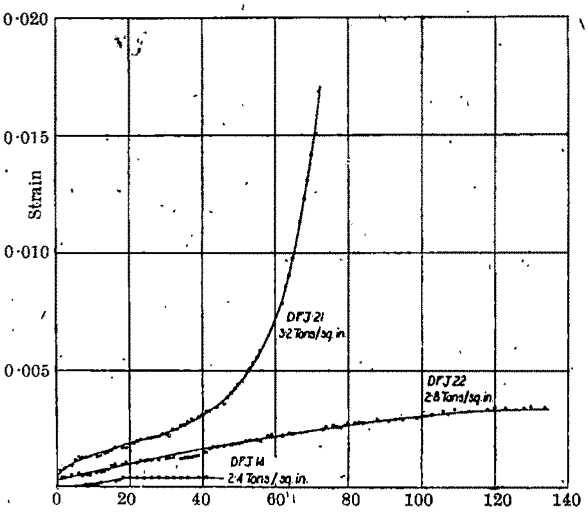

Fig. 1. Creep of a high-nickel–high-chromium steel at 800° C.

Certain experiments which Miss Charmian Sinclair has been carrying out with me on the flow of metals under constant stress throw light on this point. The metal in question is a pure lead (Tadanac virgin lead, of purity approximately 99·99 per cent) which was prepared by extrusion at 100° C. and kindly supplied to me by Mr. G. L. Bailey, director of the British Non-Ferrous Metals Research Association. It turns out that this metal, although normally stable at atmospheric temperature, recrystallizes under stress, the crystals increasing in size from about 0·05 mm. up to about 0·3 mm. linear dimensions.

Fig. 2 shows length against time for a range of stresses, each stress being maintained constant during flow by an Andrade–Chalmers constant stress bar[5]. It will be seen that the form differs markedly from that obtained with normal metals, which is represented by the broken line, obtained with normal lead extended at about the same temperature at constant stress. For the recrystallizing lead there is a stage of accelerated creep during the first ten minutes which is followed by a final creep at an approximately constant rate. The form of creep curve during the first ten minutes resembles closely that for the steels at high temperature. Whether the steels would, at like extension, ultimately creep at constant rate, cannot be said, but the 2·8 tons/sq. in. curve suggests that it may be possible.

It is clear, in any case, that recrystallization during creep has a fundamental effect on the form of creep curves. So far we have examined the wires microscopically only before and after creep, and noted the very marked recrystallization that has taken place. We are about to examine the state of crystallization at different stages of creep, with the object of connecting the rate of creep with the process of recrystallization.

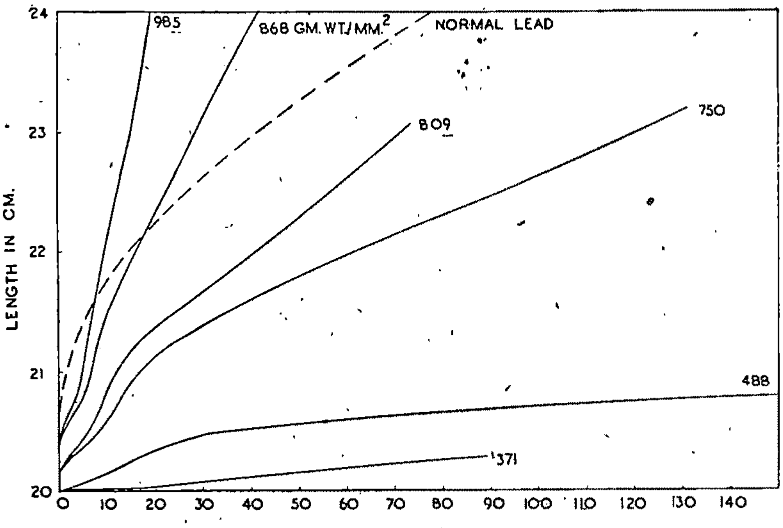

Fig. 2. Creep of a very pure lead which recrystallizes under stress

Creep of Metals Subjected to Compression Stress

THE progress of creep in metals in the case of applied tensile stress is usually divided into three stages: (1) an initial decelerating rate of creep (primary creep); (2) a stage of approximately constant creep-rate (secondary or steady state creep); (3) a final accelerating state of creep, leading to fracture (tertiary creep often ascribed in materials undergoing large deformations to increase in stress due to decreasing cross-sectional area as creep proceeds).

We have conducted creep tests in compression at a constant load on some typical creep-resistant nickel–chromium alloys, which in tensile creep tests at the same initial stress and temperature show the three stages of creep referred to above. During the course of these tests, we have made the following observations:

(*a*) The creep-rate in the secondary or constant state stage of creep is approximately the same in tensile and in compressive tests.

(*b*) Tertiary creep occurs in compression as well as in tension, and its onset in compressive tests occurs at approximately the same time as in tensile tests.

(*c*) Whereas in tensile tests, creep in the tertiary stage proceeds at an accelerating rate until fracture ensues, in corresponding compressive tests creep proceeds in a series of accelerating and decelerating rates.

Fig. 1 illustrates a typical compressive creep test showing primary and secondary creep, the onset of tertiary creep, and a stage of decelerating and accelerating creep in the tertiary stage. Fig. 2 is a comparison of the tensile and compressive creep of samples of identical alloy under the same conditions of stress and temperature. The accelerating rate of tertiary creep in the tensile specimen and the stages of acceleration and deceleration in the tertiary creep stage of the compressive creep specimen should be noted.

We believe that this is the first observation of tertiary creep in compression tests. The fact that it occurs after the same time has elapsed in both tension and compression tests suggests that its onset in tension tests in these materials is in no way connected with the increase in stress resulting from a reduction in effective cross-sectional area due to creep. Increase in stress due to decrease in cross-sectional area is, of course, a factor accelerating creep in materials such as pure metals tested at stresses that cause relatively large deformations to occur during the creep test.

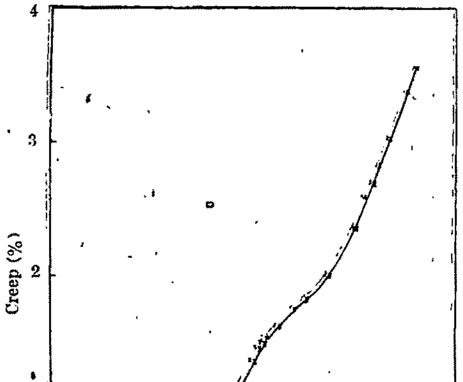

Fig. 1. Creep test in compression on a complex nickel-chromium alloy under a stress of 3·5 tons/sq. in. at a temperature of 900° C.

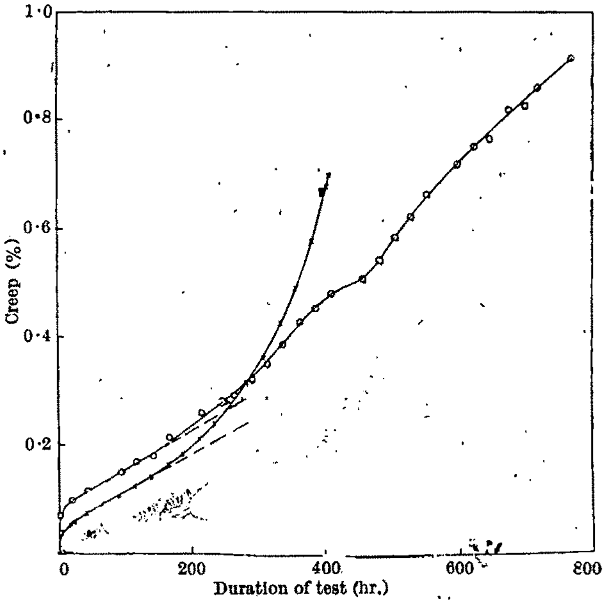

Fig. 2. Comparison of tensile and compressive creep under a stress of 9 tons/sq. in. at a temperature of 815° C. x, tension creep test; o, compression creep test

It is suggested that a study of the differences between tensile and compressive creep in the tertiary stage may enable certain deductions to be made about the mechanism by which this stage of creep occurs. We tentatively suggest that, in both tension and in compression, tertiary creep is initiated by atomic rearrangement in the most heavily strained zones adjacent to the crystal boundaries, the onset of which may be determined by the amount of strain which the specimen has undergone. This rearrangement may represent the initial stages of a recrystallization process similar to that which has been stated by Greenwood and Worner[1] to be responsible for successive stages of accelerating and decelerating creep in tensile creep tests on lead and lead alloys. If this acceleration of creep-rate occurs by slip processes in the zones adjacent to the boundaries, it will lead to misfit at grain boundaries and, in the case of applied tension, to the formation of fissures at the grain boundaries at large angles to the applied stress, causing a further acceleration of creep-rate and rapid fracture. The formation in tension of such fissures at or near the grain boundaries and an accompanying decrease in density have been demonstrated by Hanson and Wheeler[2].

In compressive creep, we suggest that such fissures in boundaries making large angles to the direction of the applied stress cannot form as readily as in the case of tensile creep, so that creep may proceed by a series of hardening processes, due perhaps to the blocking of dislocations, and to recovery processes akin to the onset of recrystallization. These hardening and recovery processes may be localized in material adjacent to the grain boundaries, due to the stress concentrations in these regions brought about by flow in the boundaries.

We intend to make further correlation of compressive and tensile creep in materials free from the metallurgical complexities of commercial creep-resistant alloys, in order to obtain further data.

We are indebted to the Ministry of Supply, under the sponsorship of which the work was conducted, for permission to publish these results, and to Mr. W. H. Mayes, who was responsible for the construction of the apparatus, which was similar in principle to a machine in use at the National Physical Laboratory.

Isotopic Assignment of the α-Activity of Samarium

THE recent report by Dempster[1] that the earlier conclusion of Wilkins and Dempster[2] regarding the α-active isotope of samarium is unreliable makes necessary the revision of a great deal of past speculation. Previously the α-activity was assigned to ^{148}Sm ; now it appears that ^{152}Sm is almost certainly the isotope responsible.

It is the object of this note to point out that (once the shock of this radical re-assignment is forgotten) the new result is more easily reconcilable with other evidence than is the old. Earlier arguments attempting to explain why the range of elements neodymium (60) to samarium (62) is particularly liable to α-disintegration, and seeking to compare this range of elements with that neighbouring upon polonium (84), the most α-unstable of the classical radioelements, are not affected; but the details of the picture are filled in with much greater consistency than before.

The outside evidence of most direct relevance is that regarding isotopic hyperfine structure in the spectra of neodymium and samarium. With samarium, Schüler and Schmidt[3] found an anomaly in the relative separations of the isotopic hyperfine structure components ; later a closely similar anomaly was found by Klinkenberg[4] with neodymium. For all other even-numbered elements so far examined the isotopic hyperfine structure consists of components which to a good approximation are linearly spaced in respect of mass number on a frequency scale (at least so far as the components of even mass number are concerned). With samarium this linear spacing is interrupted by an abnormally large interval between the components of mass numbers 150 and 152, and with neodymium there is similarly an unusually large interval between components of mass 148 and 150. Basically these anomalies are interpreted as evidence for an abnormal increase of nuclear radius (more exactly of the proton-occupied volume of the nucleus) between ^{150}Sm and ^{152}Sm, as also between ^{148}Nd and ^{150}Nd ; scarcely less directly they may be regarded as evidence for a 'discontinuous' decrease in nuclear binding energy as between these pairs of even isotopes. Classifying on this basis the samarium isotopes of mass numbers 144, 148, 150 and the neodymium isotopes 142, 144, 146 and 148 as 'tightly bound' and the samarium isotopes 152, 154 and the neodymium isotope 150 as 'loosely bound', it is clear that the only possibility for α-disintegration from a loosely bound samarium to a tightly bound neodymium is, in fact, the possibility $^{152}\text{Sm} \xrightarrow{\alpha} {}^{148}\text{Nd}$. There is every reason to expect, therefore, that ^{152}Sm is the predominantly α-active samarium isotope. A tentative suggestion to this effect was, in fact, made by Schüler and Schmidt[3] in 1934.

Returning to the comparison of the α-activity of samarium with that of the classical radioelements—and with the α-activities of the polonium isotopes in particular—we may note how recent results serve to correct previous misconceptions. Previously it has been too readily assumed that α-activity becomes more pronounced as the mass number (A) decreases ; for polonium (84), at least, the work of Howland, Templeton and Perlman[5] shows that this is not the case. The annexed table gives the total energy of α-disintegration (E) of the isotopes from $A = 206$ to $A = 218$. The pattern of variation is obvious from the figures quoted. The 'pure α-active' species for this element ($Z = 84$) are the isotopes of mass numbers 208, 210, 211, 212, 213 (?), 214 and 216 ; these are the species which correspond to the stable isotopes of the elements[6] of atomic number $Z \leqslant 83$. It is clear that the maximum α-disintegration energy in this case ($Z = 84$) belongs to the even-numbered isotope, which occupies the mid-place in the sequence of β-stable species $A = 208, 210, 212, 214, 216$. The case of samarium is seen in comparison to be not so different as might previously have been supposed.

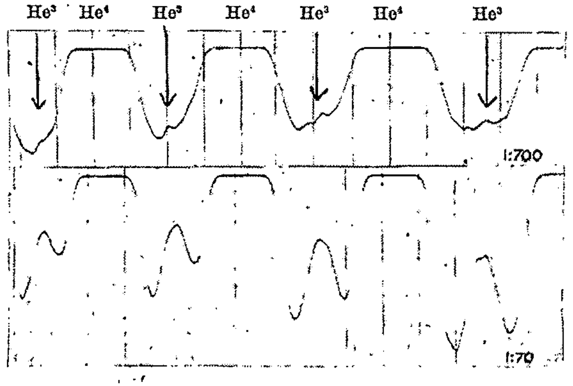
Spectrum of Helium-3

THE possibility of obtaining samples of helium in which the isotope of mass 3 has been enriched allows the isotope shifts in the arc spectrum of this element to be investigated. The first samples, which had kindly been made available to us by Dr. Rollin and Mr. Hatton[1], had been prepared by means of thermal diffusion, and contained helium-3 in a concentration of 1 : 700. With an ordinary Fabry Pérot étalon, the detection of satellites several hundred times weaker than the main line is impossible, owing to the finite background intensity of this instrument. This difficulty was overcome by the use of two étalons, of equal spacings, in series. By suitable choice of apertures, distances and orientations of the wedge-shaped étalon plates, it was found comparatively easy to avoid secondary reflexions. The method appears to be very useful for the investigation of faint satellites very close to strong lines.

The upper part of the figure shows a photometer tracing of the line 2^1S–3^1P, 5015 A., photographed with two étalons in series, each of spacing 0·318 cm. The peaks due to helium-3 are small, but clearly visible between the large peaks of helium-4, which appear flattened at the top as the result of over-exposure. A sample in which the helium-3 had been



further enriched to a concentration of 1 : 70 by the method of evaporation at very low temperature[1] became available later, and its spectrum is shown in the lower part of the figure. Comparison of the two tracings demonstrates the enrichment achieved by this method. Rough photometric estimates of the intensities agree with the concentration of the samples measured in the mass spectroscope.

The background which appears in the tracings is largely due to the finite width of the helium lines, not to instrumental effects. The intensity ratio 1 : 700 does not, therefore, represent the limit of sensitivity of the method.

In the highly enriched sample, the satellite could also be photographed and measured with a single étalon. The helium-3 line was found to have a separation of $-0\cdot83 \pm 0\cdot03$ cm.$^{-1}$ from the helium-4 line.

A theory of isotope shifts in two-electron spectra due to mass effects has been developed by Hughes and Eckart[2,3]. It is based on the assumption of hydrogen-like wave functions with effective nuclear charges. On the basis of their calculations for the $2P$ states, the value of the effective charge Z_s for the $1s$ electron in the $3P$ states can be assumed to be 2·00, giving a value of $Z_p = 0\cdot996$ for the $3p$ electron in the 3^1P state. This gives an isotope shift of the line 2^1S–3^1P of $-0\cdot77$ cm.$^{-1}$, which is outside the limits of error of the experimental value. The difference may be due to the approximations contained in the theory, or to the influence of factors other than the pure mass effect.

Details of the spectroscopic method will be published elsewhere.

Vibrating Electrodes in Polarography

THE constant diffusion conditions necessary for polarographic work have hitherto been attained by use of the dropping-mercury electrode, the streaming mercury electrode[1], the rotating platinum micro-electrode[2], or even by a fixed micro-electrode and a constant electrolyte streaming-rate[3].

We have found that a platinum micro-electrode vibrating at a constant frequency (100 cycles per second) with an amplitude considerably greater than its linear dimensions gives constant diffusion conditions, and with such an electrode we have obtained reproducible polarograms. The electrode is free from irregularities due to external vibration and gives smoother curves than those obtained with the dropping-mercury cathode.

Evidence of Geological Age against Decay of Tin-115 to Indium-115 by Electron Capture

ACCORDING to a rule of nuclear stability, it is improbable that two neighbouring elements (neighbouring Z) have stable isotopes of the same nominal mass, that is, stable neighbouring isobaric pairs should not exist. A few apparent exceptions to this rule are known, one of which is the pair, $_{49}In^{115}$ and $_{50}Sn^{115}$.

In indium, the relative abundance of In^{115} is 95·5 per cent, and in tin, the relative abundance of Sn^{115} is 0·4 per cent: In^{115} is thus an abundant indium isotope, whereas Sn^{115} is a minor tin isotope; this has caused some nuclear physicists, for example, Fluegge[1], to suggest that Sn^{115} has probably decayed by orbital electron capture to In^{115} during the life-period of the earth.

Recently Kohman[2] has discussed β-stability of all nuclei, and by means of his β-stability diagram has been able to predict that for the pair, Sn^{115} and In^{115}, Sn^{115} should be unstable, which accords with the above suggestion by Fluegge[1]. Kohman[2] refers to an earlier paper by Eastman[3], which, on the basis of atomic mass calculations, would also favour decay of Sn^{115} to In^{115}. A later paper by Eastman[4] invokes geochemical evidence, namely, the association of traces of indium with tin in tin minerals, as indicative of electron capture decay to indium-115. Since this publication appeared, many more tin minerals have been analysed, notably cassiterite; in some, traces of indium have been found, whereas in others no indium could be detected. Of considerable interest is a paper by Itsikson and Rusanov[5] which reports analyses of many specimens of cassiterite from the U.S.S.R.: the useful conclusion is made that although specimens of cassiterite associated with sulphide veins usually contain traces of indium, specimens from pegmatite are likely to be free from detectable quantities.

Direct observations on the production of characteristic X-radiation which would result from electron capture decay by tin-115 have been made by Zingg[6]. His results are inconclusive, as, in three specimens of tin he examined, very feeble activity could be detected, whereas in a fourth specimen no activity was observed. Later, similar observations by Rusinov and Igelnitzky[7] failed to reveal the presence of any X-radiation, and these authors set the minimum value for the period of half-life (T) for Sn^{115} as greater than $1\cdot0 \times 10^{13}$ years.

As a result of the considerable diversity of opinion and experimental evidence mentioned above, I have attempted to utilize geochemical evidence of the type referred to before, for establishing whether significant decay of tin-115 by electron capture decay has taken place or not. For this purpose, three requirements have to be fulfilled: the absolute age of the mineral has to be known; this age must be extremely great—

if possible, of the same magnitude as the age of the earth—and, finally, contamination by non-radiogenic indium has to be reduced to an absolute minimum.

The age of the earth appears very likely to be of the magnitude of 3,000 × 10^6 years, according to Holmes,[8] Houtermanns[9] and some astronomical data, and minerals of the greatest geological age yet reported are, according to Ahrens[10], from pegmatites in south-eastern Manitoba, Canada: the age of these pegmatites from this area is given as 2,100 × 10^6 years and is based on strontium and lead age measurements. These pegmatites are thus of extreme age, the magnitude of which is comparable with the age of the earth. In greisenized portions of some of these pegmatites, cassiterite occurs, and according to Itsikson and Rusanov[5], pegmatitic cassiterite is likely to be freest from the presence of even traces of indium. Consequently, a spectrochemical analysis was made of a specimen of cassiterite from pegmatite (south-east Manitoba), which had been kindly supplied by the Department of Mines and Natural Resources, Winnipeg, Canada. Only a doubtful trace of indium was observable, equivalent in quantity to the limit of detection for the spectrochemical determination of indium in cassiterite, which, with the aid of a series of standards, was estimated to be very close to 0·0001 per cent indium. This value represents the maximum concentration of indium in the specimen of cassiterite, and as the tin content of pure cassiterite is about 75 per cent Sn, the period of half-life (T) for tin-115 is equal to or greater than 5·0 × 10^{12} yr.

From this analysis of cassiterite, several conclusions may be made: (1) The relative abundance of indium-115 (95·5 per cent) in natural indium, and the paucity of tin-115 (0·4 per cent) in natural tin, cannot be attributed to electron capture decay of Sn^{115} during earth periods. (2) The presence of traces of indium in many tin minerals is not due to decay of tin-115 because, even in the oldest known specimen of cassiterite (2,100 × 10^6 yr.), only a doubtful trace (equal to or less than 0·0001 per cent indium) could be observed. (3) Should tin-115 have decayed very feebly indeed to indium-115, the rate of decay is extremely slow, and T (Sn^{115}) is equal to or greater than 5·0 × 10^{12} yr., which accords with the observations of Rusinov and Igelnitzky[7], who determined T as 1·0 × 10^{13} yr. by direct experiment. The spin[11] of In^{115} is 9/2, whereas that of Sn^{115} is 1/2; this difference in spins is very great indeed, and should decay occur, an extremely long life would be expected.

The spectrochemical analyses were made in the Department of Mineralogy and Petrology, University of Cambridge; grateful acknowledgment is made to Prof. C. E. Tilley for providing facilities for carrying out the investigation.

Human Colour Vision and Granit's Theory

GRANIT'S brilliant experiments on electroretinography[1] have led him to postulate photopic and scotopic 'dominator' mechanisms which have all the properties of independent brightness receptors, and 'modulator' mechanisms which may give cues to colour because they are sensitive to relatively narrow bands of the visible spectrum. Many of the animals on which the experiments were done, such as the cat, rat, guinea pig and frog, are totally colour blind to the best of our knowledge; and Granit points out (*a*) that most laboratory animals, with the exception of the snake, possess very few modulators relative to their dominator units; (*b*) that these proportions in the highly colour-sensitive human fovea are not known; (*c*) that the demonstration of modulator units is not in itself a proof of the presence of colour vision.

In a previous communication the factorial analysis of a battery of colour vision tests, including red, orange, yellow, yellow-green, green, blue-green, blue, violet and purple, with corresponding brightness measurements, was reported[2]. This seemed to give strong support to a four-colour theory of the Hering or Houstoun type. There is, however, every reason to suppose that such results might be co-ordinated with Granit's findings.

In a subsequent series of tests, the following results were obtained on a group of 357 subjects with normal colour vision, the brightness readings being separately inter-correlated with the measurements of colour sensitivity, though there was, of course, only a single brightness-level measurement for each colour pair, because the tests were of the Rayleigh equation type.

Test	Factor loadings		
	I	II	III
Red	0·070	+0·767	−0·226
Yellow	0·007	+0·104	−0·451
Green	0·121	−0·683	−0·069
Blue	0·459	−0·061	+0·236
Y-blue brightness	0·179	−0·268	+0·395
R-green brightness	0·252	+0·141	+0·115

It seems reasonable to suppose that factorial analysis would tend to reveal any consistent patterns of variation in the sensitivities of the underlying visual mechanisms, and therefore to indicate their number and nature. In this analysis, as in the other analysis of the results for normal subjects[2], the first factor is light but represents general variabilities irrespective of differential hue sensitivity; the second factor is heavy and represents variability in the bipolar red-green sensitivity; and the third factor is light and represents variations in yellow-blue sensitivity. The variations of brightness sensitivity are distributed among the three factors. 'Blue' and brightness are the best representatives of the general factor; red-green brightness tends to vary with red, but yellow-blue brightness with green in the second factor; both yellow-blue brightness and red-green brightness with blue in the third factor.

It might be suggested that the general factor represents variations in the sensitivity of the dominator mechanism for photopic vision. The second factor would then represent the variations in sensitivity for the red-green modulator unit and the third factor the variations for the yellow-blue modulator unit. Three important conclusions may be drawn from this application of Granit's theory to the result of tests of colour vision upon normal human subjects: (*a*) that four modulators would be sufficient, namely, red, yellow, green and blue; (*b*) that they must be regarded as operating in two bipolar units, red with green, and yellow with blue; (*c*) that brightness is to some extent dependent on the modulator units.

A Simple Technique for the Differential Staining of Lignified Cell Walls

THE common methods for differential staining of lignified plant tissue are specific when used correctly, but minor errors in procedure may lead to unsatisfactory results. The following simple technique has been found a reliable, cheap and quick supplement to the other methods available, and to give good results in unskilled hands.

It is based on the observation that, in all cases which we have examined, a colourless solution of benzidine imparts an orange or yellow colour to lignified cell walls, but causes no colour change in cellulose or in cutinized or suberized walls. The most intense orange coloration is produced by a saturated solution of benzidine in glacial acetic acid. With lowered acidity the solubility of benzidine decreases, the resulting solutions producing a less brilliant but equally specific staining. This develops in sections after thirty seconds to sixty seconds treatment; but as the solution is colourless and the reaction occurs only in lignified tissue, sections can be left in it for many days without 'overstaining', and there is no need for subsequent washing or 'destaining'. This is an advantage when handling sections in bulk, it being possible to transfer them to the solution directly after cutting and to hold them in it until it is convenient to mount them with or without a light counter stain. A less acid solution may also be used for the vital staining of tissue, as vascular systems of leaves, etc., are clearly visible after impregnation. The colour is unaffected by treatment with alcohol or xylol, and has shown no signs of fading in sections exposed to daylight for three months.

In view of the constitution of benzidine, the chemistry of the staining is possibly similar to that of the colour reaction given by lignified cell walls with a number of primary and secondary amines.

Influence of Time and Temperature of Storage on Dye-Reduction Tests in Milk

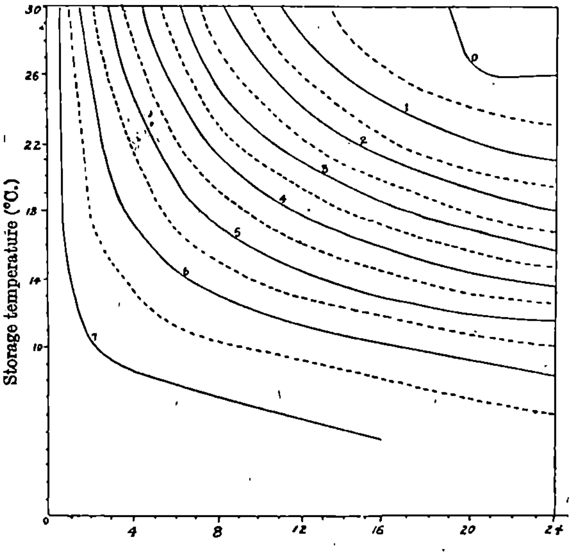
IN applying overseas data to the determination of suitable dye-reduction standards for the grading of milk in New South Wales, it soon became apparent that particular attention would have to be paid to the influence of time and temperature of storage on the reduction time[1]. Apart from Smythe's work in Queensland[2], for a relatively limited storage time, there is surprisingly little information concerning the significance of these factors, and it is thought that our own approach and results will prove of interest beyond Australia.

The primary aim of our work has been to study the trends in decrease of dye-reduction times with storage time and temperature, including within the range of our experiments conditions likely to be encountered both in Australia and Britain. By this means it has been possible to bring to bear on our own problem the large body of British experimental work and practical experience, as well as to arrive at a temperature compensation scale for local variations that are likely to be more extreme than those encountered in the United Kingdom. Samples from six producers, representing extremes of production conditions, were taken at the completion of milking and stored at combinations of time and temperature, namely, 4, 8, 12, 16, 20 and 24 hr. and 0, 10, 14, 18, 22, 26 and 30° C. Methylene blue and resazurin tests (both at 37·5° C.) were then performed on each sample.

With the advice of Dr. D. B. Duncan, of this Department, it has been possible to use the results so obtained to study the trends with storage time and temperature as a regression surface, having twelve parameters and allowing for quadratic variation with storage time and cubic variation with temperature as well as interaction between the two. The results for the modified methylene blue test are shown in the form of a contour graph (reproduced herewith) in which the lines join the points of equal reduction times. From this graph it is possible to arrive at an approximation of reduction time associated with any combination of storage time and temperature; but more fully the surface is represented by the equation:

$$Y = 7{\cdot}2 - 0{\cdot}005\,t + 0{\cdot}00027\,t^2 - 0{\cdot}047\,T + 0{\cdot}019\,tT - 0{\cdot}00044\,t^2T + 0{\cdot}0047\,T^2 - 0{\cdot}00293\,tT^2 + 0{\cdot}000039\,t^2T^2 - 0{\cdot}00010\,T^3 + 0{\cdot}000048\,tT^3 - 0{\cdot}00000005\,t^2T^3\,;$$

Y is reduction time in hours, t is storage time in hours, T is storage temperature in °C.



Influence of time and temperature of storage on methylene blue reduction time. Lines join points of equal reduction time in hour – half-hour intervals

The surface represented in the graph and the accompanying equation appears, from a consideration of British temperatures (as recorded at Kew), to pass through the British Summer Standard (12 hr. storage at mean summer air temperature of 16° C., reduction time, 4½ hr.). However, the height of the surface can be conveniently altered by adjustment of the constant (7·2 in the above equation) to comply with any other standard.

Similar methods have been applied to data for the resazurin tests obtained on the same milks, thus permitting an accurate comparison of the time–temperature trends together with a comparison of existing British standards for both tests. Our data suggest, in fact, that the standard set for resazurin[3] is appreciably lower than that for methylene blue[4].

Furthermore, by taking account of data for the individual producers, it is possible to determine the degree of discrimination associated with each combination of time and temperature; so that the storage period can, within certain practical limits, be adjusted to obtain greater sensitivity in the test.

Other advantages of our approach might then be summarized thus. Comparable standards can be established for widely different conditions of production. A reasonable adjustment in acceptable reduction time can be made throughout the year according to temperature and time of storage, thus freeing the test of its present undue dependence on atmospheric temperature[5]. The length of time between production and testing can be allowed for in evaluating producers. The time–temperature effect can be related for several tests.

Pregnancy Test using the Male Toad

THROUGH the kindness of the originator of the test, who forwarded us a supply of *Bufo arenarum* Hensel, we have recently been able to carry out the Galli Mainini male toad test for pregnancy.

Ten ml. of urine are injected into a lymph sac of the toad. It is important to note that the animals seem particularly susceptible to drugs in the urine. But apart from this fact, the urine samples need no special preparation. The appearance of spermatozoa in the urine, which constitutes a positive result, is observed by low-power microscopic examination of a drop or two obtained by a pipette from the cloaca. We have found the test to be positive in 2–4 hr., depending on the time of examination. In some cases, a positive result occurs in one hour and the amount injected may be reduced to 5 ml. Within 20–24 hr., re-sampling of the urine shows either absence of spermatozoa or fewer and non-motile spermatozoa. The temperature averaged 22° C. during the tests.

In a consecutive series of fifty inoculations, we have encountered no false positive and only one false negative. This latter may be explained on the basis that the urine sample was abnormally dilute. The series included gonadotrophins, cases of confirmed pregnancy, incomplete abortions, uterine fibroids, secondary amenorrhœa and normal women.

Over a limited series, we have confirmed claims made for this test by Galli Mainini[1], Lima and Pereira[2], who used *Bufo marinus*, and Wiltberger and Miller[3], using *Rana pipiens*. It remains to be seen whether *Bufo bufo* or *Rana temporaria* will be equally suitable.

Shortage of Scientific Text-Books

As one who is associated with a group of firms dealing with all aspects of the production, publishing and retail selling of learned, scientific and technical books, I have read with very considerable interest the article on the survey of the present shortage of scientific text-books in Cambridge carried out by the Cambridge Branch of the Association of Scientific Workers which appears in *Nature* of August 7, p. 209. Unfortunately some of the conclusions appear invalid.

That there is a shortage of text-books in this category there is no question. Under present conditions it is inevitable that in any discussion of this shortage mention must be made of the Board of Trade, so let me at once pay tribute to the officers of the Board of both the Import Licensing and Raw Materials Divisions, who have been approachable at all times, and, I am convinced, have done their utmost, often in circumstances of considerable difficulty, to ameliorate the position.

That too great a proportion of British scientific text-books has to be exported is a statement difficult to support. Export there is and must be; but there are few scientific books which are exported to an extent which harms the home market.

With regard to American books, the surveyors appear to be under one serious misapprehension. Despite what they say, it is possible for any individual requiring any American learned, scientific and technical book to go into a bookshop (preferably one with some experience of this type of work) and to order that book. If it is in print in the United States, there is no reason why it should not be in Great Britain within a month of the order being placed.

Secondly, with regard to the 200 per cent quota: this figure, taken in conjunction with the 'single copy' *modus operandi* referred to above, should be adequate to meet requirements at the present time. I agree that it is not so; but the reason lies not in the 200 per cent total figure but in the allocation of that figure on the basis of individual firms' imports during either the last half of 1939 or the first half of 1940. The reason is quite simple—in ten years the emphasis of business has altered as between firms, both booksellers and publishers, in Great Britain so that the ratio of supply does not fall in the regions where the requirements are greatest.

If the 200 per cent total were to be re-allocated (a difficult but not insuperable task) according to present-day demands, many of the difficulties would be eased and indeed might very well disappear, provided the 'single copy' method of working is used intelligently. This point has been put on more than one occasion to the Board of Trade who, I believe, are shackled by Treasury restrictions.

With regard to the Survey's comments on British books, there is one misunderstanding which should be got rid of immediately: for books in this category paper is no longer a restrictive factor in so far as quantity is concerned. The Board of Trade in conjunction with the Publishers' Association maintain a reserve, known as the Moberly Pool, for 'educational' books: this has been gradually increased as circumstances allow, and it has been administered with the utmost fairness and with the approbation of all concerned. After fairly extensive inquiries, I have yet to find a publisher with a sound case who has been refused an allocation which he required for a book in the categories under discussion. There still are, of course, difficulties with paper in regard to quality and price.

The only other difficulty with material is in regard to cloth. This would appear to be a difficulty not of the basic essentials being unavailable but of the output of the Lancashire mills. Again, both with cloth and with boards there are reasons for complaining of quality and of price.

The production obstacles which any publisher must confront at present are very slowly easing in the field of printing, although a shortage of apprentice entrants as compositors during the war years has caused a bottle-neck which it will take some years to overcome.

In binding books the position is bad indeed. But the lack is not of material, apart from cloth, but of machinery: nearly all of it American. The Board of Trade has been helpful in every way, but the fact must be faced that the source of supply is limited in the beginning, so long as there are so few British types of machines suitable for the work which must be undertaken.

But the main difficulty with regard to all production hold-ups is the shorter working week and the policy which has been psychologically instilled into the minds of so many of the workers that they can expect more pay for less work. This factor cannot be overstressed, and until it is remedied we can expect no real improvement in the supply of scientific text-books.

JOHN GRANT

Oxford.

MAY I be permitted three comments on Mr. Grant's letter. With regard to his third paragraph, the original article did not suggest that too great a proportion of scientific text-books is being exported. It was stated "that a good case can be made out for the large percentage of book production which goes to export". It was emphasized, however, that this trade and reputation "are in danger unless our total volume of 'learned, scientific and technical' book production is increased, so that both the home and export markets may be better supplied".

On Mr. Grant's fourth paragraph, it was specifically stated in the article that no account was taken of books imported as single copies as this factor was not thought to be important so far as students are concerned. In fact, our experience is that it takes 8–10 weeks to get such books and often longer.

If binding causes great difficulties, have the publishers considered bringing out temporary editions of some of the most needed books in an unbound form similar to *Nature* or *Hansard*. Students to-day could be relied on to treat them with due care.

ROY INNES

Association of Scientific Workers,
15 Half Moon Street,
London, W.1.

International Exchange of Scientific Information

IN the editorial article in *Nature* of August 14, in criticizing a recent statement of the Atomic Scientists' Association, it is argued that collaboration between scientific men east and west of the 'Iron Curtain' may be undesirable, because it is likely "to promote, for the present, a one-way traffic to the disadvantage of the Western democracies". This view was expressed in the same words on July 14 by the editor of the *Economist*, who, professionally concerned as he must be with economic policy and its effect on foreign affairs, may be excused for including scientific ideas among the commodities available for exchange. But the same view expressed in *Nature* suggests a change in the traditional policy of the journal, which has always stressed the international aspects of science, and it shows strikingly the way in which military considerations can affect the outlook of scientific workers and lead them to adopt against their will a totalitarian view of their function. It is therefore necessary to inquire whether these military considerations really make it necessary to abandon the whole tradition of science, and to break off such contacts as are still possible with the scientific workers of Eastern Europe.

It is stated in the editorial that the man of science in totalitarian countries is essentially a servant of the State, and that it is treason for him to divulge any knowledge save as the State allows. But in fact this statement is true only in the opinions of the men who control the Government of the U.S.S.R.; we may be sure that most scientific men in the satellite countries would not take that view of their functions, and probably many outstanding men in Russia itself hold other views.

Our policy, then, of allowing the free exchange of ideas even across frontiers is one which our scientific colleagues in these countries will feel to be the right policy, and in which we shall have their sympathy. It should not be lightly thrown away through the fear that some small help might be given to their military science.

THE CORE OF THE INSULIN MOLECULE

By Dr. J. A. V. BUTLER, D. M. P. PHILLIPS
AND
Miss J. M. L. STEPHEN
S. A. Courtauld Institute of Biochemistry,
Middlesex Hospital, London

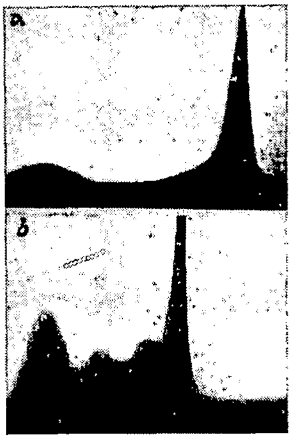
ON account of its stability and well-defined crystalline character, insulin is a favourable point at the present time to attack protein structure. Its composition is probably better known than that of any other protein. The stoichiometrical molecular weight, that is, the least weight into which all the analytical values can be fitted, is 12,000, indicating a comparatively simple character[1]. Recent researches[2] show that the most prevalent molecule in aqueous solution has a molecular weight approximately four times as great, dissociating somewhat in acid and moderately alkaline solutions. The facts, therefore, suggest that the basic unit of insulin is a molecule of molecular weight 12,000. X-ray analysis has indicated that three of these units form the unit cell in crystals[3].

Knowledge of the chemical structure of insulin has been greatly advanced by Sanger[4], by the use of the reagent fluorodinitrobenzene, which reacts with the amino-groups of proteins under very mild conditions, forming a bond which resists acid hydrolysis, so that the amino-acid residues which form the amino-end of the peptide chains can be identified. Sanger has shown in this way that the sub-molecule of insulin consists of four chains, of which two terminate in glycine and two in phenylalanine residues. These chains are presumably held together by the –S–S– links provided by the cystine, of which six exist in the molecule. Sanger has shown that by oxidation with hydrogen peroxide in formic acid solution, according to the method of Toennies and Homiller[5], these disulphide links are oxidized and a product is obtained which has been shown by adsorption analysis[6] and electrophoretic analysis[7] to consist of three or four distinct substances. A fraction was obtained from this which contained no phenylalanyl residues and contained no lysine, arginine, histidine, or threonine, and in which all the terminal residues are glycine[8].

Another line of approach has emerged from the work of Woolley[9], who has found in the partial hydrolysates of various proteins a growth-promoting factor for *L. casei* which he calls 'strepogenin'. Insulin was found to be a particularly rich source of this substance. Strepogenin appears to be a peptide which occurs in insulin at the end of one or more of the chains, since elimination of the free amino-groups of insulin with fluorodinitrobenzene destroys the activity[10]. Woolley has also found that the dinitrophenyl derivative of insulin and of oxidized insulin can be digested by pancreatin. The products have been fractionated by a series of counter-current distributions by the method of Craig[11], and several crystalline dinitrophenyl peptides obtained[12] containing, in addition to dinitrophenyl glycine, the following amino-acids: (1) glutamic acid, (2) glutamic acid, serine, threonine, valine and leucine; (3) same as (2) plus aspartic acid; (4) glutamic acid, serine, tyrosine and leucine; (5) same as (3) plus *iso*leucine and cysteic acid.

A study of the enzyme breakdown of insulin has been made by Butler, Dodds, Phillips and Stephen[13]. It was found that whereas pepsin breaks the insulin molecule into fragments with a molecular weight of *c.* 3,000 and an average chain-length of about seven residues, chymotrypsin removes from the molecule a number of smaller peptides of molecular weight *c.* 800, leaving a more massive residue which is precipitable in 0·25 *N* trichloroacetic acid. After extracting the trichloroacetic acid with ether, it was found that its molecular weight is 4,000 ± 1,500. In two separate experiments, it was found to contain between 80 and 90 per cent of the total amount of cystine of the insulin molecule. It thus appears that the result of chymotrypsin digestion is to remove parts from the ends of the insulin chains, leaving a 'core' in which the chains are united by –S–S– links. This core is slowly broken down by the long-continued action of chymotrypsin.

Attempts made to separate the smaller peptides in the trichloroacetic filtrate have on the whole been unsuccessful. Paper chromatography with phenol divided them into four broad bands[14]; but it has been found that this is at best only a partial separation, since eluting the bands separately and repeating the process gives a very similar pattern. Paper chromatography with butyl alcohol – acetic acid as solvent has given a series of fifteen distinct spots, most of which are peptides; but it has not so far been possible to isolate these substances in sufficient quantity for examination.



(*a*) Electrophoretic diagram of the core material (C11*B*) at *p*H 8·0. (*b*) Electrophoretic diagram of the oxidized core (C11*B*) at *p*H 7·0. Experiments by Dr. J. M. Creeth. Ascending boundaries shown.

Further examination of the material precipitated by trichloroacetic acid has provided evidence of its essential homogeneity. It gives a single sharp boundary in electrophoresis (Fig. *a*). Dr. K. O. Pedersen, of the Institute of Physical Chemistry, Uppsala, has kindly determined its diffusion coefficient by the free diffusion method[15], obtaining the figures $D_A = 18{\cdot}6 \times 10^{-7}$, $D_M = 18{\cdot}3 \times 10^{-7}$ at 20°. This corresponds to a molecular weight, assuming a spherical and unhydrated molecule, of approximately 5,000. All the amino-acids of insulin are present, except possibly arginine, threonine, proline and phenylalanine, which have either been absent or shown up weakly in one of the fractions resulting from oxidation of the core.

After oxidation by hydrogen peroxide in formic acid solution, the product shows four well-defined peaks in the electrophoresis diagram (Fig. *b*). The slowest of these (left-hand peak in the diagram) may be due solely to the δ-anomaly, since this material cannot be equilibrated with the buffer by dialysis. Their isoelectric points are below pH3, indicating the presence of strongly acid groups, as may be expected from the presence of cysteic acid. When the oxidized material is taken in aqueous solution to pH 4·5, a small fraction corresponding to Sanger's fraction B, but containing only 5 per cent of the material, separated. This could be shown to contain *all* the amino-acids of insulin, that is, those present in small amounts and undetectable in the whole core are concentrated in this fraction. The remainder lacks arginine, proline, lysine, threonine and phenylalanine. It is possible that the small separated fraction is a small amount of material, carried along by the core but not really belonging to it, or to a portion of core not broken down as much as the remainder. The oxidized soluble substance was also found to be complex by paper chromatography in butyl alcohol–acetic acid mixtures and showed three or four separate spots with ninhydrin.

The core can also be converted into its dinitrophenyl derivative by Sanger's method. The product, when examined by paper chromatography with phenol, gives two distinct yellow spots, a main spot and a fainter one, and is therefore apparently not completely homogeneous. Different digests behaved differently in the relative intensities of these spots, and it is probable that the core is more digested away in some cases than in others. After hydrolysis with 6N hydrochloric acid, the dinitrophenyl core was found (in one experiment) to yield the following amounts of dinitrophenyl amino-acids, calculated for a core molecular weight of 5,000: glycine, 2·5 molecules; with smaller quantities of valine (0·4 molecule), terminal histidine (0·8 molecule) and ε-lysine (0·5 molecule). This core was 40 per cent of the insulin molecule. Another core (36 per cent) gave glycine, 2·4 mol.; valine, 0·3 mol.; histidine, 1·7 mol. The glycine figures involve a considerable correction for the decomposition of dinitrophenyl glycine during the hydrolysis and may require revision. The fractional numbers and the variation of different cores would suggest that the core molecules are not all of the same kind.

After oxidation of the dinitrophenyl derivative, the product is divisible into two portions: (1) soluble in water, (2) insoluble in water. It has been found that the soluble portion can be separated into three bands, the first rather diffuse and the other two sharp, by passing its aqueous solution down a starch column. The insoluble fraction can be made soluble by dissolving in dilute ammonia. After neutralizing with acetic acid, it also gives three bands similar to those of the original soluble portion. Since a mixture of the soluble and insoluble parts when dissolved together also gives the three bands, it is concluded that the original soluble and insoluble portions are either made up of the same or of closely related substances. The proportions seem, however, to be different. Work on characterizing these fractions is being continued.

We have frequently observed in our work on the digestion products of insulin that a preparation became insoluble after thorough drying, and that treatment with dilute acid or alkali was necessary to bring it into solution. The removal of water apparently causes loose bonds to be established between the peptide chains, possibly through the interaction of neighbouring acidic and basic groups to form an insoluble complex, which is only broken by the application of acids or alkalis.

We acknowledge with pleasure financial assistance by Messrs. Courtaulds, Ltd., and Messrs. Imperial Chemical Industries, Ltd.; advice and assistance in characterizing dinitrophenyl derivatives by Dr. F. Sanger, the technical assistance of Mrs. I. D. R. Goodwin and the interest and help of Prof. E. C. Dodds. We are also indebted to Dr. J. M. Creeth for the two electrophoretic diagrams reproduced, and to Dr. K. O. Pedersen for his examination of the core material, details of which he is publishing elsewhere.

BIREFRINGENCE AND ORIENTATION-RATE OF THE LEPTONES OF PROTOPLASM

By Dr. HANS H. PFEIFFER
Laborat. für quantitativ Polarisationsmikroskopie, Bremen

PRESENT knowledge indicates that the submicroscopic or 'leptonic' state of organised gels[1] consists of a framework of reciprocally associated macromolecules or molecular bundles (micelles). Their orientation-rate within the gels, as observed in polarized light, decides whether there are formed anisotropic gels in which the particles (leptones) are arranged parallel to each other, or isotropic gels in consequence of perfect disorientation of the leptones. Between these two limiting cases, there are many textures with differently graded orientation-rates. If a system contains imperfectly oriented leptones, the orientation-rate, and hence the birefringence, will be increased by tension[2]. Thus the birefringence will reach a maximum when the leptones are maximally oriented. But the theoretical relation between birefringence and orientation-rate is somewhat indefinite, for even in the case of perfect orientation the rate of grid-like disposition cannot be comprehended apart from the remainder. Moreover, isotropy includes cases of perfect disorientation as well as adjacent organisation in the immediate environs (*Nahordnung*). Further complications in consequence of different rates of swelling and extension cannot be taken into consideration here. The distribution function of O. Kratky, P. H. Hermans and co-workers[3], defining the frequent repetition of the different directions of leptones, has been obtained from the extension-rate of the gels and their orientation state *before* the extension. But with biogels, the deformation-rate during the unextended, that is, isotropic, state is not appreciable. Frey-Wyssling[3] has derived expressions describing the field or cone of scattering of leptones by means of a single angle. This method, however, gives only a comparative measure of the increase of orientation. I have now been able to investigate the *streaming birefringence* of protoplasm and to calculate the orientation-rate of its leptones.

By means of much improved experimental arrangement, it has been shown that protoplasm sucked up into a capillary becomes doubly refractive if it is made to flow by a compressing force[3]. Continuing these experiments[4], the birefringence has been found to be negative with regard to the flow direction. Hence, evidence is available that the effect first described by Pfeiffer is produced by lipids of the protoplasm. The interpretation of the experiment is perhaps doubtful, and we do not know whether, by sucking up the material, the protein chains are straightened out and the lipids have to follow the orientation, or whether the lipids, by the interlocking, are released and become able to arrange themselves parallel with one another. But the flow experiment with protoplasm makes it possible to evaluate the *maximal* streaming birefringence, and hence a given orientation-rate, and to make other measurements (for example, length of leptones, to be described shortly elsewhere).

For the quantitative study of the birefringence of protoplasm flowing within a capillary, the latter has been embedded in a liquid of the same index of refraction as the protoplasm[5] (about 5 mm.^{3} of the *Physarum polycephalum* plasmodium grown on oat agar). A detailed description of the apparatus and the method of stimulating the flow have been published already. The quantitative studies relate to the character (sign) and the phase difference (intensity) of the anisotropy of protoplasm, and to its direction of extinction. If, as with protoplasm, long-chain molecules are not oriented at 45° to the gradient of flow, but at angles between 45 and 90°, it is necessary to define the direction or *angle of extinction*, χ (*Auslöschwinkel*, angle of isocline, *Kreuzwinkel*). For this purpose we find the orthogonal position of the crossed nicols in a lateral, extinguished flame of the capillary[6]. The flow capillary is fixed and the optical polarizing equipment adjusted as a whole; then the angle required results from the extent of the turning movement against the direction referred to. The *negative sign of anisotropy* results from the use of a Red I (gypsum) plate oriented, like the object, with its direction of fast and slow transmission at 45° to the planes of polarizer and analyser, and, as usually employed, the slower vibration direction (larger index) extending from the upper right to the lower left quadrant of the field of view. The *phase difference* of the object (Γ) has been measured with a very sensitive Brace compensator (rotating λ/30-mica compensator) and the half-shadow wedge according to Macé de Lépinay at varying velocities of flow[7]. The polarizer is set at 0°, the object brought into focus and oriented in a diagonal position (45° to the polarizer plane), and the compensator and the analyser are inserted (nicols crossed). After the compensator has been adjusted so that the field surrounding the object is maximally dark and the angle noted (average of five to ten readings), the compensator is then moved round so that the object is maximally dark (five to ten readings again). If the difference between the two series of readings is β, then the retardation is $\Gamma = (\lambda/30) \sin 2\beta$, and the birefringence, as usual, $\Delta n = \Gamma/d$, where d is the thickness of the preparation.

In regard to the rate of orientation, it is necessary to mention especially the *extinction angle*, χ. As usual, it increases with the flow gradient and the viscosity, and decreases as the temperature goes up; but above all, it depends upon the length of the leptones. The extinction angle has been found to have values between 61° and 76°. For each series of experiments with successively increased shearing forces, the angle shows a constant value over the period during which the preparation could be kept free from denaturation. For smaller flow velocities smaller values of χ are found, which, however, are well reproducible and do not show any ageing effects. Sometimes the measured values show more scatter than could be expected from an estimation of the usual experimental errors. Hence this scattering must be due to variations in the origin and nature or special character of the material. If the same measurements are taken by varying the λ (using a cadmium spectral lamp or a perfect monochromator), with other conditions constant, a similar set of characteristic curves is obtained.

The movability of the protoplasmic leptones is measured, according to Boeder[8], by the *rotation diffusion constant*, D_R. The quotient of the gradient of flow dv/dn and of D_R represents the parameter α, which is related to a precise *direction density* ρ. If α is increasing, the maximum of the accumulation is displaced to higher χ-values. The gradual transition from lower to higher χ-values, depending on the decreasing gradient dv/dn, takes place, of course, the earlier the lower D_R is obtained. Using only one measurement of χ at a known gradient dv/dn, the constant D_R and the parameter α are, theoretically, measurable with protoplasm double refractive by flowing.

By measuring the *phase difference* Γ at an extinction angle χ sufficiently far from 45°, we are able to calculate the *maximal birefringence*, that is, the double refraction in case of orientation of all the leptones. With regard to the coefficient μ, with which we have to multiply the measured phase difference, in order to obtain the saturation value of birefringence, we find :

χ	50	55	60	62½	65	67½	70	72½	75	77½	80	85
$\Delta n_{\text{obs.}}/\Delta n_{\text{max.}}$	0·09	0·15	0·23	0·28	0·35	0·40	0·44	0·48	0·51	0·54	0·56	0·61
μ	11·1	6·7	4·3	3·5	2·9	2·5	2·3	2·1	1·9	1·8	1·7	1·6

We have, however, to accept the limitation to the *plane* problem; the three-dimensional problem does not seem to be capable of solution with our present knowledge. With this restriction, only a limited number of leptones become arranged parallel with the direction of flow; calculation indicates 20–30 per cent, and for very long chain molecules only 3–5 per cent. Further complications are to be expected if the leptones should be deformed by the flow[10].

CARNEGIE INSTITUTION OF WASHINGTON

THE feature of most general interest in Dr. Vannebar Bush's report as president of the Carnegie Institution of Washington for the year ended October 31, 1947 (Year Book No. 46), is his review of the range of the Institution's activities, and particularly the relation of the Institution to Federal support. Dr. Bush points out that the Institution has always recognized that research stands or falls by the men who are responsible for its prosecution, and from its earliest days has consistently sought the exceptional man and provided him with facilities and resources to pursue problems which he discerned and by his own methods. Latterly, in establishing its own research centres, the Institution has recognized that such centres are of ultimate value in the search for knowledge only as they are utilized by groups of investigators including leaders of proved skill and acumen and younger men of real promise. Dr. Bush pays a high tribute both to the creative work of the Institution's scientific staff, and is also satisfied with the general plan of organisation of the work and with the effectiveness of its administration. Discussing next the termination at the end of the War as expeditiously as possible of all research for the Government, to enable the Institution to return to its own programmes of fundamental research and its policy of free dissemination of results, he considers the policy of the Institution of not seeking broad support for its research from federal funds in the light of the increasing support of fundamental investigation from Government funds.

Dr. Bush considers that the policy governing grants by the National Government for fundamental research has so far been characterized by vision and wisdom, and that it is highly important the federal policy should continue. Acceptance by the Carnegie Institution of such funds for enlarging its research programmes should depend first, however, on any such research activity forming as nearly as possible an integral operative and administrative unit, or that the activity can be terminated easily if the support terminates. The activity should, moreover, be one both intrinsically worth while and a natural addition to the Institution's own regular programme. It should also be one to which the Institution can genuinely contribute by reason of the skills and operations of the regular staff and the presence of the regular programme. Finally, the conditions under which the Institution accepts such funds should in no way infringe the independent status of the Institution in pursuing its own regular programme of research, and they should be genuinely adapted to the prosecution of fundamental investigation of the highest quality.

In reviewing the research activities of the past year, Dr. Bush notes that 1946–47 was the first since 1940 in which all departments and divisions had been fully engaged on normal programmes. Continuing his investigation at Mount Wilson Observatory of the general magnetic fields of stars, Dr. H. Babcock has surveyed likely stars down to the sixth magnitude, finding magnetic fields stronger than 1,000 gauss in several and a polar field of 5,500 gauss in one. At the Geophysical Laboratory, the development of a new type of pressure apparatus has facilitated the study of equilibrium relations in hydrous mixtures. In the magnesia – silica – water system, all the commoner natural hydrous silicates of magnesia, as well as two anhydrous silicates, could be prepared with only the solid phases and vapour present. Equilibria up to 900° C. at pressures up to 15,000 lb. per square inch and at 800° C. up to 30,000 lb. have been determined. New procedures developed in the Department of Terrestrial Magnetism have indicated that, within the accuracy of the measurement, the strength of the magnetic field of the earth has not changed during the past 30,000 years. A large increase in the intensity of cosmic radiation at all observing points except at the equator was observed at the time of a marked solar flare and radio blackout on July 25, 1946.

Extensive study of a wide variety of plants in the Division of Plant Biology indicates that the chloroplast pigments essential in the photosynthetic apparatus of all plants have changed but little in the evolution both of the species in major taxonomic groups and of the main groups themselves. The active pigments of present-day green algæ are thus the same as those possessed by their fossil ancestors, and results obtained in the further study of the unicellular alga *Chlorella* have shown that while the chemical composition of the alga varies widely with the culture conditions selected for its growth, the nature of the chlorophyll pigments is unchanged. The grass-breeding programme of the Division of Plant Biology undertaken in co-operation with the Soil Conservation Service of the United States Department of Agriculture has yielded hybrids of high promise owing to their combination of favourable yield, resistance to disease and continued activity in dry summer weather. The species used in the crossings produce most of their seed asexually but, unexpectedly, it was found that two-thirds of the hybrids between asexual parents were themselves sexual.

The aerosol method developed in the Department of Genetics for investigations involving the treatment of *Drosophila* with chemical solutions has been used for testing the power of various carcinogenic agents to effect mutations in genes. Most of the carcinogens thus tested were mutagenic, and most substances related chemically to the carcinogens but not themselves carcinogenic did not produce mutations. Dr. Dobzhansky's work in the same Department has shown that the proportion of certain types of *Drosophila* in wild populations changes with the season. The fly thus shows substantially the same kind of differentiation into altitudinal races as Drs. J. Clausen, D. D. Keck and W. M. Hiesey, of the Division of Plant Biology, found for species of *Achillea*.

In the Department of Embryology, Dr. L. B. Flexner and his colleagues, using radioactive sodium and heavy water, have obtained further evidence that the ratio of water within the cells of newborn infants to extracellular water increases as growth proceeds, and further studies of the permeability of the placenta are being pursued. Dr. S. R. M. Reynolds is investigating the physical forces involved as the uterus accommodates itself to its growing contents, as a contribution to the fuller understanding of the problems of advanced pregnancy and of parturition.

More detailed accounts of the investigations in progress or completed during the year are to be found in the departmental and divisional reports which follow that of the president, and to which bibliographies are appended. From this it is only possible to select a few further investigations for mention.

such as the attention being given by the Geophysical Laboratory to thermal measurement and to studies on radioactivity, and by the Department of Terrestrial Magnetism to studies of the earth's crust and of the upper atmosphere as well as to cosmic ray research. A feature of this report is the review of the magnetic survey and observatory programme of the Department over the period 1904–46. In the Division of Plant Biology, investigations on the chemistry of chlorophyll formation have been extended to include analysis of the process at different temperatures, and in that of Embryology tests have been made of the action of a large series of dyes related to Nile Blue on tumours in mice. Full accounts of work on the organisation of the chromosome, of cryptogenetic studies of maize and *Neurospora*, of chromosome studies on gall midges, and of work on mouse leukæmia and on the genetic structure of natural populations are included in a long report from the Department of Genetics, while that from the Division of Historical Research deals with the results of the expedition to Bonampak, in Chiapas, Mexico, the field work in the Guatemala highlands and the preparation of a hand-book of ceramic technology for archæologists and a preliminary analysis of Usulatan ware.

INTERNATIONAL COMMITTEE FOR BIRD PRESERVATION

A MEETING of the European Continental Section of the International Committee for Bird Preservation held in Paris during July 17–20, under the chairmanship of Dr. Boje Benzon, was attended by representatives of Austria, Belgium, Denmark, France, Great Britain, Hungary, Italy, Netherlands, Norway, Sweden and Switzerland; though the German National Section has not yet been reorganised, the interests of that country were represented by the chief game warden of the British Zone accompanied by a German adviser and by a German adviser from the American Zone. The president of the Zoology Section, International Union of Biological Sciences, and an observer from the Natural Sciences Section of Unesco attended, and the Conseil International de la Chasse was also represented.

The chief business of the Conference was the discussion of proposals for the revision of the Paris Convention of 1902 for the Protection of Birds Useful to Agriculture, on which the International Committee for Bird Preservation commenced work thirteen years ago. In 1935 representatives of the Finnish, Norwegian and Swedish Governments drew up a Draft Convention for the International Protection of Birds which was presented at a Conference of the International Committee for Bird Preservation held in Brussels that year. After due consideration it was decided at this Conference that an entirely new Convention was not practicable and that proposals for the revision of the Paris Convention of 1902 should be put forward. Lord Justice von Seth (Sweden), on behalf of the Scandinavian countries, accepted this suggestion with the proviso that the broad outlines of the Scandinavian proposals should be maintained. The matter was then referred to an International Sub-Committee consisting of M. A. Chappellier (France), (the late) Dr. Percy Lowe (Great Britain), Prof. M. Siedlecki (Poland) and Lord Justice von Seth (Sweden), with Miss Phyllis Barclay-Smith (Great Britain) and M. Leon Lippens (Belgium) as secretaries. Each national section in Europe was then requested to send to the secretariat suggestions relating to the modification of the Paris Convention. The Sub-Committee, taking into consideration the views of all countries, drew up these suggestions into a general report to serve as a basis for the discussion of a definite final proposal.

The report of the Sub-Committee was discussed at a conference in Vienna in 1937, attended by representatives of twelve European national sections, and proposals for a revision of the Paris Convention agreed. The necessary diplomatic steps to bring these proposals to the attention of the Governments concerned were in progress on the outbreak of war.

However, at a conference held in London in June 1947, attended by representatives of fourteen European national sections, it was decided that in view of the many changed circumstances during ten years, the Vienna proposals were in need of further revision. The matter was again referred to an International Sub-Committee consisting of Dr. Boje Benzon (Denmark), M. G. Olivier (France), Mr. R. A. H. Coombes (Great Britain) and Dr. J. H. Westermann (Netherlands), with Miss Barclay-Smith and M. Lippens as secretaries as before. This Sub-Committee met in Brussels in November 1947 and drew up recommendations which were forwarded to all the national sections of Europe for their comments before being discussed at the Paris Conference in July 1948.

The proposals for the revision of the Paris Convention, 1902, agreed upon at this Conference meet not only the changed conditions and circumstances but also the change in outlook during the course of nearly fifty years. Whereas the Paris Convention was designed to afford protection to birds useful to agriculture (with emphasis on the small insectivorous birds), the scientific, educational and æsthetic aspect of bird life is now recognized, and in point of fact, at the present day, the larger birds are in need of as much, if not more, protection than the small insectivores. Therefore, the fundamental basis of the present proposals is that all birds should have some measure of protection. Far more is known about migration than was the case in 1902, and the countries are becoming more and more aware of their interdependence and obligations towards each other in this matter; it is now appreciated that it is not possible for the country in which migratory birds breed to maintain the stock unaided. The broad outlines of protection now proposed are that birds should be protected during their breeding season and, so far as migratory species are concerned, during the times of their *return* to their nesting grounds; also that birds in danger of extinction should have special protection. Allowance for exceptions is made when and where necessary in the interests of agriculture, forestry, fishing, science, education, etc., and for the special economic conditions in certain regions. It is also realized that the all-important balance of Nature should be maintained in every way possible, and that any bird which may constitute a menace to other species must be kept in check. The sentimental idea of a 'sanctuary' for all species where everything is inviolate is, in fact, no sanctuary, and there have been far too many instances of this: to take one example, tern colonies have almost disappeared under the onslaught of gulls, to whom an all-embracing 'protection' has afforded an undue advantage.

Import, export, transport, selling or buying are also dealt with in regard to species taken illegally, and eggs are considered equally with the birds themselves.

Certain methods for the mass capture or destruction of birds are condemned. This is a particularly difficult subject owing to old-established customs and widely diverging points of view and national temperaments. What is regarded as a normal state of affairs in one country may be deplored by its neighbour, and it is not easy to arrive at a general agreement, a tolerant give and take and gradual change being the only solution.

A point which was of no great importance in 1902, but which has become of vital importance in 1948, is the safeguarding of habitat which is the fundamental for the existence of any species of bird; with the rapid spread of civilization this is becoming more and more serious so far as all forms of wild life are concerned.

In addition to the Convention another important question dealt with by the Paris Conference was the International Inquiry into the status of the Anatidæ in Europe, and the progress being made in the various countries regarding this. The British Section, which has been allocated the task of correlating the information sent in from all over Europe, presented a report on the arrangements being made to carry out this work.

Other matters discussed were the conditions of transport of birds by air, a biological station on the Neusiedlersee in Austria, and the publication of the second edition of an International Ornithological Dictionary by Denmark.

The membership of the International Committee now numbers thirty-five, Iceland having been the latest country to form a national section. The headquarters are at the British Museum (Natural History), London, with further secretariats in Brussels and New York.

BIOLUMINESCENCE

THE increasing use of the fluorescent lamp in recent years has served as a stimulus to the study of the mechanism of the emission of cold light; and this in turn has led to a renewed interest in the production and utilization of such light in luminous animals. The Section of Biology of the New York Academy of Sciences held a Conference on Bioluminescence in November, 1946, and the papers submitted, which have now been published*, provide a comprehensive review of the subject.

In a general survey, E. Newton Harvey points out that about forty different orders of plants and animals, ranging from bacteria to fish, contain self-luminous species. A few of these, such as the fish *Photoblepharon* and *Anomalops*, make use of luminous bacteria housed in special pouches which can be covered or exposed at will by a sort of eyelid. Chemiluminescence in general is reviewed by R. S. Anderson. Colour, fluorescence and chemiluminescence are probably degrees in an analogous process. Emission results from the loss of a quantum of energy during the change from an excited electronic state to a ground-state with less energy, these changes being independent of high temperature. Only in comparatively recent years, with the discovery of the bright chemiluminescence of aminophthalhydrazide and dimethylbiacridinium nitrate, have systems been obtained which can rival in luminosity the substances extracted from living organisms. It was in 1886 that Dubois first demonstrated that light production in animals results from the interaction of luciferin and the enzyme luciferase. In the Ostracod *Cypridina* these two components are discharged in the form of granules from separate glandular pores and then interact in the sea water. This animal, therefore, affords ideal material for the study of these substances *in vitro*, and the recent work in this field is reviewed by A. M. Chase. The structure of luciferin has not been fully elucidated; but there is evidence that it has a relatively small molecular weight and contains a hydroxybenzene structure which is reversibly oxidized to a quinone. F. H. Johnson and H. Eyring discuss the action of pressure, temperature and drugs on the enzymes concerned in bacterial luminescence.

By far the longest paper is by J. B. Buck, who provides a comprehensive review of the anatomy and physiology of the light organ of fireflies and contributes some new suggestions on the control of light emission. There is the utmost diversity in the anatomy of the light organ in the beetles; their histology ranges in complexity from a group of loose independent giant cells, apparently without tracheæ, similar to, and perhaps identical with, the œnocytes (such as occur in *Phengodes*), to the highly complicated arrangement in *Photinus* or *Luciola* where a reflective layer containing urate granules underlies the photogenic layer. In the most complex type a rich supply of tracheæ runs vertically through the reflective layer and then enters specialized cylindrical rods of tissue which pass straight through the photogenic layer. Here they give off lateral branches which end in conspicuous tracheal end-cells by breaking up into the tracheoles which supply the photogenic cells. Buck is satisfied that the tracheoles do not enter the cells; but there is evidence that they are connected together by an ultra-tracheolar network which may, perhaps, consist of open tubes.

It is this very highly evolved system which provides some of the most intriguing problems in the physiological control of luminescence. Light may be emitted as a steady glow or in the form of brilliant flashes showing a remarkable periodicity which is under the control of the organism. It is the control of flashing which has excited most controversy. There is no doubt that the organ is supplied by nerves which stimulate it to activity. It is equally sure that the production of light is dependent upon the access of oxygen to the photogenic cells. Argument has centred around the question whether the cells are stimulated directly to produce light—perhaps by the dissolution of barriers which normally separate the enzyme from its substrate—or whether the nerves control the access of oxygen. It is well known that the endings of the tracheoles in many insects contain liquid which may be absorbed into the tissues during activity and so replaced by air. It has been suggested that the enhanced oxygen supply which then results may be the cause of the light flash; but, as Buck points out, if this change does occur in the tracheoles of the luminous organ it is more likely to be secondary to the metabolic activity of the cells. The tracheal end-cells, an enlarged form of the cells which occur in many insects where the tracheæ break up into tracheoles, are a characteristic feature of the flashing type of organ. It has often been suggested that they play some part in the process. Dahlgren described what appeared to be a sphincter around the tracheole at this point, and beyond it a structure with radiating fibres. Buck outlines a reasoned hypothesis according to which the glowing of the organ is dependent on the diffusion of oxygen into the tracheoles, while the flashes are due to the mechanical projection of 'jets' of air into the tracheole by the controlled relaxation and contraction of the sphincter mechanism in the tracheal end-cell. But he concludes that the evidence at present available is insufficient to decide between this hypothesis and that of direct nervous stimulation of enzymic activity in the photogenic cells.

V. B. WIGGLESWORTH

SYMPOSIUM ON SEARCHLIGHTS

ONE of the most important features of a scientific society is its capacity to arrange a symposium on a special feature of its activities and to publish the resultant papers. There are many subjects where the interested people are too few for the probable financial return to tempt an author to the publication of a book, and where in addition the knowledge is so specialized that no one author can easily do justice to it. The publication under review* is such, and the Illuminating Engineering Society deserves the thanks of those who, either as user or manufacturer, need to know about searchlights in some detail. The scope of the book is indicated by the sectional headings: "The Function and Design of Army Searchlights", by E. W. Chivers and D. E. H. Jones; "High-power Searchlights of Wide Divergence", by Air Commodore W. Helmore, H. K. Cameron, F. S. Hawkins, L. B. W. Jolley and L. M. King-Brewster; "Photometry of Searchlights", by H. K. Cameron, E. H. Rayner, E. R. Thomas and G. T. Winch; "The Visibility of Targets in a Naval Searchlight Beam", by W. D. Chesterman and W. S. Stiles; "Some Visibility Problems Associated with Anti-Aircraft Searchlight Beams", by S. S. Beggs and J. M. Waldram; "Aircraft Searchlights for Anti-Submarine Warfare", by Commander C. J. Carr.

There are, in addition, some twelve pages of discussion.

The meeting was held in London on April 15, 1947, and presumably the difficulties of post-war publication are responsible for the delay in the appearance of the book.

As the titles suggest, there is a marked war-time flavour about the publication, although some of the work was carried out before 1940 but has not previously been made available to the scientific public. The balance between the historical background of searchlight design, theory and photometry, and the immediate foreground of practical war-time development has been well maintained, and the result is a record which will find a place in many industrial and technical libraries.

It may come as a surprise to many that an increase in intensity of a searchlight from 100 megacandles to 500 megacandles only increases the range by some 50 per cent in clear weather and by only some 15 per cent in medium weather. One may therefore be allowed to wonder whether the effort put into the development of the larger sizes of searchlight was justified, especially as it meant the complication of additional spare parts.

Probably the part which will attract most attention is the description of the design and manufacture of high-powered projectors for such special purposes as the interception of night-flying aircraft and submarines lying on the surface of the sea. The 'Turbinlite'—to use the war-time code word—as finally designed consumed 140 kw. with a 90-cm. mirror and was supplied by batteries which could operate for four periods of 30 sec. The whole was carried in the nose of an aeroplane, and the success of the scheme was demonstrated on many occasions. Figures are also quoted for the 'Leigh Light'—used against submarines—showing that the number of U-boats seen was increased sevenfold by its use and that 11 per cent of all night attacks carried out by its use resulted in 'kills'. The specialist in photometry will find summaries of considerable value, of both theory and practice as applied to these mammoths of the illuminating engineer's industry, much of it available in convenient form for the first time. In the case of 'visibility', many of the problems only became urgent under the stress of enemy action. Some of the solutions are especially neat, such as the 'perspective' explanation by Beggs and Waldram of the case of the apparent sudden ending of a searchlight beam to an observer near the projector.

There are a number of errors and misprints which may cause difficulty, as, for example, p. 44, Fig. 17(*b*). The symbols θ and ψ appear to be interchanged. P. 45, third line, this expression has been disarranged in the printing. P. 133, in the formula the symbol φ has been omitted after K in the square brackets.

The book provides in a convenient form a technical treatise on its subject and, in addition, a record of war-time achievement of which the various authors have reason to be proud. The diagrams and pictures are clearly and well produced; but an index would have increased the reader's pleasure and the utility of the production.

W. M. HAMPTON

AFFORESTATION FOR BENGAL

ANYONE who has travelled by railway throughout India must have noticed the disparity reigning in the distribution of the forests in that country. In some parts the railways pass through great and apparently interminable tracts of forest and jungle. In others, of which Bengal forms one of the best of examples, the converse is the case. Between Calcutta and the foot of the Darjeeling Hills the traveller by railway passes over a great plain devoted mainly to the production of rice, the villages mostly in groves of palm trees, but a total absence of forest. The forest part in Bengal represents only 0·07 acre per head of population. Bengal has only 9 per cent of its surface under forest, and a considerable part of the latter is in the Darjeeling Hills and the Sundarbans south of Calcutta.

Modern conditions and demands resulting from the Second World War, to some extent, and the great necessity to improve the agricultural soils of the Province, have at length roused the authorities. These soils are not manured. The large quantities of cow dung obtained from the great herds of cattle kept by the villagers are at present, and have been for many centuries past, utilized as fuel for heating and cooking purposes. One of the objects of the projected afforestation plan for Bengal is to create plantations suitably distributed to provide fuel for these purposes and thus release the manure for its proper use. A Bill for the purpose of afforesting of waste lands and for conserving what is left of private forests was introduced in the Bengal Assembly in 1944. The Bill was enacted in April 1945, and already considerable progress has been made so far as private forests are concerned.

---

* Searchlights. A series of five papers, with the discussion on those papers and a further written contribution. Pp. 164. (London: Illuminating Engineering Society, 1948.) 17*s*. 6*d*. net.

Here we have somewhat similar provisions to the Dedication of Woodlands scheme in Britain (*Nature*, Sept. 4, p. 364). The Bengal Government has the power and the duty of telling the owner how to use his forests, and the Government will meet all expenditure for the first ten years, and in certain cases and conditions the Government may make loans to private owners. As regards the waste land, the estimated area which should be, and could be, afforested is four million acres or 9 per cent of the area of the Province. If this area was afforested Bengal would then have no less than 18 per cent of its lands under forests. Much of this area, it is said is, above the paddy fields and is of a highland nature. It is said to have been under forest once, but with the forest removed soil deterioration, leaching and erosion resulted. Yet the land is believed to be afforestable. It is a big scheme and one which will make high demands on the forest staff of the Province in all its ranks.

In the paper read by Mr. T. M. Coffey, chief conservator of forests, before the members of the Rotary Club, Calcutta, in 1947 (reprinted in *The Indian Forester*, 73, No. 11; November 1947), it is said that to carry out the programme will require to have a forest officer in every district in the Province. At present there are ten districts with forest officers and seventeen without. There can be little doubt that this is a thoroughly sound scheme—but it will require pluck, perseverance and drive and continuity in management and working to see its successful completion. If this is fully recognized, enormous benefits will be conferred upon future populations in the Province. E. P. STEBBING

THE B.B.C. QUARTERLY

IN April 1946 the British Broadcasting Corporation inaugurated a new periodical entitled *The B.B.C. Quarterly*, which was intended for those in Great Britain and abroad who are interested, professionally or otherwise, in broadcasting and its organisation. During the past two years the successive issues of this journal have contained articles on a wide variety of subjects connected directly or otherwise with the purpose of broadcasting and its administration, and with the technical and radio engineering developments which are necessary for the ever-increasing needs of modern broadcasting, including its international aspects.

More than half the contents of the first number of the third volume, issued in April, comprises a series of articles by specialists introduced and edited by Sir Arthur Salter under the general title of "The Impact of Broadcasting on Great Britain's Life and Outlook—I". The remainder of the issue consists of three articles dealing with some present-time activities of the engineering sections of the B.B.C.

In the first article, Messrs. H. B. Rantzen and J. H. Holmes describe the proposed developments which are now being undertaken to provide adequate communication facilities, mainly telephone and teleprinter, over the whole network interconnecting London and the regional broadcasting centres in Great Britain. Following this, Mr. L. Hotine gives an interesting, illustrated account of the engineering arrangements which were made for broadcasting the Royal Wedding. On this occasion, commentaries and eye-witness accounts of the processions and marriage ceremony were made in forty-two languages for the B.B.C. Home, European and Overseas Services. Provision was also made for such accounts to be given to more than fifty stations and networks in the Dominions and Colonies, and for similar facilities to be provided for the big networks and independent stations in the United States and in various European countries. Certain limited television programmes were also provided; and the success of all these arrangements is a tribute to the efficiency of all those concerned with this phase of the operation of outside broadcasting technique.

The third article deals with a subject of great and increasing importance in modern broadcasting: the suppression of unwanted radiation from medium-wave transmitters. Mr. J. B. Webb describes the manner in which spurious radiations from transmitters can, by harmonics or combination frequencies, cause interference with other broadcasting services. This possibility has become more serious in recent years, due to the increase in both the number and power of stations in operation in the medium wave band. The identification and attenuation of existing spurious radiations is often expensive and complicated, requiring the use of widespread technical facilities. But it is very clear that careful consideration should be given to possible unwanted radiations before a new service is introduced, or an increase in power contemplated at an existing installation.

FORTHCOMING EVENTS

Saturday, September 11

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, DIVISION FOR SOCIAL AND INTERNATIONAL RELATIONS OF SCIENCE (at the Dome, Brighton), at 7.30 p.m.—Discussion on "Science Across the Frontiers". (Dr. Julian Huxley, F.R.S.: Introduction; Dr. Joseph Needham, F.R.S.: "Origins and Development of the Organisation of International Scientific Co-operation"; Prof. Pierre Auger: "Present Scientific Activities and Programme of UNESCO"; Dr. Paulo Carneiro: "The International Research Institute of the Hylean Amazon").

Sunday, September 12

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE (at the Dome, Brighton), at 8 p.m.—Rt. Hon. Viscount Samuel, P.C.: "Science and Philosophy".

Monday, September 13

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE (at the Royal Pavilion, Brighton), at 8 p.m.—Prof. J. D. Bernal, F.R.S.: "Waves and Beaches".

Monday, September 13—Tuesday, September 14

SOCIETY FOR GENERAL MICROBIOLOGY (at the University, St. Andrews).—Scientific Papers.

Monday, September 13—Friday, September 17

HORTICULTURAL EDUCATION ASSOCIATION (at Edinburgh).—Autumn Conference.

Wednesday, September 15

ROYAL INSTITUTE OF CHEMISTRY (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Dr. A. J. Turner: "Research on Linen".

Thursday, September 16

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 5 p.m.—Prof. C. von Fürer-Haimendorf: "Wealth and War among Two Himalayan Tribes".

Friday, September 17

Society of Leather Trades' Chemists (in the New Chemistry Building, The University, Leeds), at 2 p.m.—Mr. G. S. Adair, F.R.S.: "Recent Work on Osmotic Pressures, Membrane Equilibria and Solubility Factors of Proteins in the Light of the Work of Procter" (Third Procter Memorial Lecture).

Royal Institute of Chemistry, Newcastle-upon-Tyne and North-East Coast Section (in the Chemistry Department, King's College, Newcastle-upon-Tyne), at 3 p.m.—Symposium on "Polarography and Infra-Red Spectroscopy".

Friday, September 17—Monday, September 20

Association of Special Libraries and Information Bureaux (at Ashorne Hill, Leamington Spa).—23rd Annual Conference.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer, and an Assistant Lecturer, with special qualifications in Organic Chemistry, and a Lecturer in Physiology—The Secretary, The University, Edmund Street, Birmingham 3 (September 18).

Technical Officer, State Advances Corporation of New Zealand, Wellington (with a university degree, or its equivalent, in Applied Science, and a thorough knowledge of timber entomology, timber pathology and timber preservation)—The Official Secretary, High Commissioner for New Zealand, 415 Strand, London, W.C.2 (September 25).

Lecturer in Geology, within the Department of Agricultural Chemistry, and an Assistant Lecturer in Plant Diseases in the Department of Agricultural Botany—The Secretary and Registrar, University College of North Wales, Bangor (September 25).

Assistant in the Science Services Department, London Headquarters—The Director, Personnel Department, British Council, 3 Hanover Street, London, W.1 (September 25).

Lecturer (Grade II c or II b) in Petroleum Production Engineering—The Secretary, The University, Edmund Street, Birmingham 3 (September 30).

Biochemist with experience of research in cellular metabolism or enzymology for a research post in the Department of Lactational Physiology, to assist in the investigation of the intermediary metabolism of the mammary gland—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, Berks (September 30).

I.C.I. Research Fellowship in Pharmacology—The Secretary of University Court, The University, Glasgow (September 30).

Reader or Senior Lecturer in Applied Mathematics in the University of Adelaide—The Secretary, Universities Bureau of the British Empire, 32 Woburn Square, London, W.C.1 (September 30).

Lecturer in Psychology in the United College, St. Andrews—The Secretary, The University, St. Andrews (September 30).

Assistant Lecturer in Biochemistry—The Registrar, King's College, Strand, London, W.C.2 (September 30).

Senior Assistant in the Pathological Department—The Director, West Midlands Forensic Science Laboratory, Newton Street, Birmingham 4 (October 1).

Lecturer (Grade II c or II b) in Mining (Coal)—The Secretary, The University, Edmund Street, Birmingham 3 (October 1).

Research Assistantships (2) for work on (*a*) Physical and Chemical Aspects of Selective Flotation, and (*b*) Mining Research Problems—The Registrar, The University, Leeds 2 (October 4).

Senior Scientific Officers, and Senior Experimental Officers, for analytical work involving modern physico-chemical methods, in the Chemical Inspectorate (Atomic Energy), Ministry of Supply—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2281 (October 7).

Principal Scientific Officer or Senior Scientific Officer (with first- or second-class honours degree in metallurgy, and experience in the metallography of light alloys) in the Ministry of Supply Headquarters in London—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2279 (October 8).

Lecturer in Medical Entomology—The Secretary, Department of Entomology and Parasitology, Liverpool School of Tropical Medicine, Pembroke Place, Liverpool 3 (October 30).

Botanists (2) to assist in the preparation of a Flora of East (Tropical) Africa, which is being undertaken by the Royal Botanic Gardens, Kew—The Under-Secretary of State, Colonial Office, Research Department, Sanctuary Buildings, Great Smith Street, London, S.W.1 (October 31).

Lecturer in Mathematics and Physics in New England University College (University of Sydney), Armidale, N.S.W.—The Secretary, Universities Bureau of the British Empire, 32 Woburn Square, London, W.C.1 (October 31).

Senior Lecturer (Grade I) in the Department of Geophysics—The Secretary, The University, Edmund Street, Birmingham 3 (November 13).

Production Pile Manager, and an Instrument Manager, in the Department of Atomic Energy, Windscale Works, Sellafield, Cumberland—The Staff Section, Ministry of Supply, Department of Atomic Energy, Risley, Warrington, Lancs.

Civilian Lecturer in the Department of Applied Mechanics of the Royal Naval College, Greenwich—The Secretary, The Admiralty (C.E. Branch I), London, S.W.1.

Demonstrator in Physiology—The Secretary, Charing Cross Hospital Medical School, 62 Chandos Place, London, W.C.2.

Laboratory Technician (experience in electronics essential)—The Director, Neurological Research Unit, National Hospital, Queen Square, London, W.C.1.

Technician (Grade B)—The Area Pathologist, Musgrove Park Hospital, Taunton.

Entomologists and Plant Pathologists in the Scientific Department of the East African Groundnut Scheme—The Personnel Manager (Scientific), Overseas Food Corporation, Unilever House, London, E.C.4.

TELEVISION DEVELOPMENT IN BRITAIN

AN important statement was issued on August 24 outlining the Government's policy on the development of television in Great Britain. It will be recalled that the Television Committee, under the chairmanship of Lord Hankey, issued its report early in 1945 with a number of specific recommendations on the manner in which, after the War, a public television service should be resumed and developed in Britain (see *Nature*, 155, 615; 1945). Acting with commendable speed and efficiency, the B.B.C. implemented the first of the recommendations by reopening the London Television Service from the Alexandra Palace Station in June 1946. Next, with the view of extending the existing service to other parts of the country, work was begun on a similar station near Birmingham.

Following a further recommendation of the Hankey Committee, the present Television Advisory Committee under the chairmanship of Lord Trefgarne was appointed, and has recently been examining the technical characteristics of the B.B.C. television system in the light of the latest developments which have taken place both in Great Britain and elsewhere. It is considered that the improvements in the quality of the picture presented by any of the alternative systems are slight from the point of view of the ordinary viewer, and are not sufficient to justify a change of system which would make all the present British receiving sets obsolete. Moreover, any change, such as the addition of another hundred or two hundred lines to the existing 405-line standard of definition, would prejudice more substantial improvements, including possibly colour, at a later date. Such developments need further prolonged research before they can be realized in practice, and so far as can be foreseen, this will take several years.

On the advice of Lord Trefgarne's committee, based upon the above considerations, the Postmaster-General has now announced that the London television station will continue to operate for a number of years on the 405-line definition system, and that the same system is being adopted for the Midlands station, and is proposed for other British stations. This timely re-affirmation of another of the recommendations of the Hankey Report puts an end to the uncertainty which has been created from time to time by the claims and propaganda for other systems. It also clears the way for the radio industry to prosecute its plans for developing television markets both at home and abroad. Now that the public has been given a reassurance that the existing system will be maintained, the industry is planning to produce half a million sets during the next three years. Also, every effort will be made to demonstrate the advantages of the British system which, if it were adopted as the standard in Europe, could provide a highly developed source of programmes and benefit from Great Britain's unique experience of television.

Work on the Midlands station at Sutton Coldfield is being pressed ahead, and it is hoped to open it in the autumn of 1949. The station, although working on the same basic 405-line system as the London station at Alexandra Palace, will have increased powers of the vision and sound transmitters of twice and four times respectively. The carrier frequencies used will be in the neighbourhood of 60 Mc./s., and the station, with its aerial system on a mast 750 ft. high, will have a reception range of approximately fifty miles. The Post Office is providing alternative radio and cable links to convey programmes from London to Sutton Coldfield. The B.B.C. is working out proposals for further television stations on the 405-line system, with the next station in the north of England. The completion of this development should make television available to the greater part of the population of Britain, and set a standard of service which other countries may wish to follow.

DEMOGRAPHY BETWEEN THE TWO WORLD WARS

Europe's Population in the Inter-war Years

By Dudley Kirk. (League of Nations: Economic, Financial and Transit Department, Publication 1946. II. A.8.) Pp. xii + 312. (Geneva: League of Nations; London: George Allen and Unwin, Ltd., 1946.) Paper, 15*s.*; cloth, 17*s.* 6*d.*

THE Office of Population Research, at Princeton, has abundantly justified its creation by issuing book after book of invaluable data often otherwise difficult to obtain. The book now reviewed is of primarily historical interest, as 1939 is almost lost in antique mist so far as demographic data and political units are concerned. Yet the data for those days must to a large extent remain our guide for the future in spite of the millions of displaced persons and the holocausts of victims of war and dictatorships.

The book is a modification of an earlier plan for a demographic atlas and it is well illustrated with maps and cartograms; but the author wisely emphasizes that a thousand persons in, say, northern Russia may be far more significant than a thousand people in some large urban centre; and on the other hand, he does not forget that, were spatial relations the only or even the main factor, London and the Low Countries would be the distribution centre for Europe. The student of population is always in trouble about the variable connotation of *rural* and *urban*, and this is one of many reasons why we should be grateful to Prof. Kirk for this book with explanatory discussion rather than only an atlas. A small community, of dormitory type, may be called rural simply because it is two or more miles from a town, and on the other hand, a large agricultural community, some attaining 50,000 people, may be called a town.

Estimates for Roman imperial territory run between twenty-three and thirty millions, so the population of all Europe at that time may have been some millions above this. Setbacks in the Dark Ages, through the black death and during the wars of religion, held back increase, so that estimates for 1600 are about one hundred millions, and people increased only slowly until 1750 when roads, communications, faster ships, banks, manufactures and so on started the great modern spurt, to 187 millions in 1800, 266 millions in 1850, 401 millions in 1900 and 540 millions about 1940. The fastest growth, be it noted, came between 1850 and 1900 when war devastation was relatively slight.

North-western and Central Europe had become before 1930 an area of incipient population decline, whereas in the U.S.S.R. increase is still very rapid; in fact, some fear a tendency to multiplication for some time so rapidly that standards of living may tend to sink to those which are such an unhappy feature of the monsoon lands of Asia. Another aspect of the situation is shown in the estimate (p. 64) that by 1970 there will be about 6·6 millions less men of military age in North-western and Central Europe but 13·2 millions more in the U.S.S.R. Military losses, excess civilian deaths and birth deficits together make war losses about 22 millions. Military losses in the Second World War were heavy on the eastern front but less elsewhere. The losses through systematized murder were very great, especially in Poland and Yugoslavia and Greece. It is estimated that the War's reduction of numbers in the U.S.S.R. was such that the population in 1946 was only equal to that in 1940 before the slaughter began. That equality was more or less attained gives an indication of the height of the birth-rate even during the War. The rise in birth-rates in Western Europe since 1945 may be a consequence of changes in social attitudes and in income schemes, but it may be in a considerable degree a result of the return of the men from the War. The dramatic falls in emigration to the United States after 1924 and to Canada and Latin America after 1930 are notable as a pointer to the reduced opportunities of open spaces. The emigrant would now tend to join an American proletariat, and in many cases he rather joins the proletariat in his own country and swells the prevalent discontent; movements from southern Italy to Milan and Turin are an important factor in Italian affairs. But, on the whole, birth-rates in cities are lower than in the countryside; and territory under Soviet influence generally proscribes emigration as a political crime.

Migration within Europe in the nineteenth century led to a large increase of population in the Ukraine; but in the twentieth century the most notable fact was the movement of Poles, Italians and some Spaniards to France, usually to try to cultivate the poorer soils or to do menial work, sometimes thereby making more 'superior' jobs for Frenchmen. In parts of south-east and north-east France aliens and naturalized persons were more than 10 per cent of the population about 1930; but the economic blizzard sent some Poles back to their native land. The immigrants to France naturally included a large proportion of men between twenty and forty-five. Parts of the south-east Plateau Central have lost population heavily. A renewal of migration within Europe on a large scale might become revolutionary in its effects; it proceeds, however, quietly and very effectively, generation after generation between Scotland and England in both directions.

Expectation of life has been lowest in Rumania and Yugoslavia, with Greece, Bulgaria and the U.S.S.R. a little better. It is highest in the Netherlands, Sweden, Denmark, Norway and Switzerland. Rumania in 1936–39 still lost more than 15 per cent of its babies in their first year of life.

The study of agricultural population could have been made more profitable by using more fully data collected by Dr. C. J. Robertson for a conference on rural life in 1939 and other analyses which show the crowding, under-employment and poverty of rural populations on several parts of the Loess zone of mid-Europe, a zone occupied from the early third millennium B.C. by peasants and clinging to traditional ways which the original fertility of the soil seemed to permit. In some parts of the Loess zone the yields of crops are very low, the holdings are miserably small, alternatives to farm work are far to seek, birth-rates remain high as usual among populations near the margin of subsistence. These parts would be better if 30–50 per cent of the population could be moved away. Even modernization of methods of cultivation would give only very partial relief.

But we must not ask for too much. Prof. Kirk has given us a mass of valuable data with a notable absence of tendentious arguments. The book should be in all serious libraries. H. J. FLEURE

ANCIENT EGYPTIAN MATERIALS AND INDUSTRIES

Ancient Egyptian Materials and Industries
By A. Lucas. Third edition, revised. Pp. xi+570. (London: Edward Arnold and Co., 1948.) 25*s*. net.

THIS book deals with a branch of prehistoric archæology in the Nile valley which the late Mr. Lucas made especially his own. So often prehistorians are mainly concerned with early sequence dating and a classification of the ancient objects found. But Mr. Lucas was interested in the details of the manufacture of everyday objects and of how and whence the necessary materials were obtained.

Although primarily dealing with the Nile valley and Egyptology, much of what he wrote can, with modification, be applied to other regions—at least from Neolithic times onwards. A glance at some of the chapter headings shows the kind of problems Mr. Lucas set himself to solve. For example, he asks what adhesives were used? These were required for many purposes such as sticking sickle-blades into their hafts and preparing surfaces for tomb-paintings. In the latter case it had been thought that white of egg (from the eggs of wild-fowl, as barndoor hens were at that time unknown in the area) was used as a ground, but now on further investigation this does not seem so likely. But beeswax, glue, gypsum, resin, solder, etc., have all been identified. The need for beeswax led to the extensive cultivation of bees: some resins occurred locally, but the aromatic varieties used in perfumes, etc., had to be imported from southern Arabia. All primitive peoples manufacture some sort of alcoholic drink. What materials did the ancient Egyptians use for the purpose from predynastic times onwards? It seems evident that both beer and wine were known, though it was impossible to produce any kind of spirit, as the process of distillation was unknown until much later. It appears to have been a new discovery in the time of Aristotle. What kinds of building stone were used, and how was granite cut at a time when steel was unknown? What mortar was used? How were finely made statuettes carved from very hard stones, and how were holes for suspension bored in such things as beads, amulets and the like? "Cosmetics are as old as vanity." Yes, indeed, and perhaps we may be thankful that eyelids are no longer painted green, though blood-red nails are still with us. The green mineral malachite (a hydrated copper oxide) was used, being ground to powder on hard stones and made into a paste. Woodash fires (the ash containing alkali) over quartz pebbles, which had been so utilized as mortars, may have led to the discovery of the well-known blue glaze. Lead glaze came later. What metals were known at the various periods, and where were they mined? How was mummification accomplished? What was the process employed to obtain flat sheets of writing material from the pith of the plant papyrus? These and many other fascinating questions are posed and answered by Mr. Lucas.

Finally, there is given a brief historical survey, and the above information is fitted, as it were, into the historical sequence.

It is very pleasant to find a chemist, trained in accurate determination, dealing with such prehistoric problems. There are some prehistorians who have reached back to their subject from their later historical studies; they bring with them the historian's outlook. Others again reach up from geological investigation and bring to bear on the problems the geologist's point of view. Here we have the chemist's outlook, and it is both novel and stimulating. Of course, Mr. Lucas was not the first of his kind to envisage such investigations; but he of all others had particularly made it his own. He opened up the new field in his earlier editions, and this revised and more definitive volume will be welcomed by all who are directly or indirectly interested in the way men lived in the Nile valley in the remote past. M. C. BURKITT

RECENT RESEARCHES IN PHYSIOLOGY

Annual Review of Physiology
Victor E. Hall, Editor; Jefferson M. Crismon, Associate Editor; and Arthur C. Giese, Associate Editor. Vol. 10. Pp. xi+552. (Stanford, Calif.: Annual Reviews, Inc., 1948.) 6 dollars.

IT is rather a sobering thought that within three years of the end of the War a book of more than five hundred pages is required to review the written contributions to one small corner of biological science. With such a literary output some kind of annual survey is clearly necessary, if only as a time-saving measure, to guide the worker or student to those articles relevant to his interests. Reviews, however, are something more than intelligently arranged catalogues, for they can present a periodical appreciation of the state of knowledge in the various fields and in this way help a worker to follow general trends in branches of the science other than his own. A third value to be attached to such surveys is that, by their general dissemination, they can exert a unifying influence which may be considered a direct contribution to a truly international spirit.

Viewed from these three points of view, the tenth volume of "Annual Review of Physiology" has great merit. A wide range of subjects is covered in its twenty-three sections, the only notable deficiency being "Excretion", and this omission is due to circumstances beyond editorial control.

As a guide to publications, each section provides a generous bibliography and there are large author and subject indexes. Certain sections have their bibliographies arranged in alphabetical order; this has a distinct advantage over a chronological arrangement where the reference hunter is concerned.

The most valuable sections are those in which the authors have made some assessment of the significance of the results recorded, or have attempted to harmonize evidence from various sources or to formulate plans for the resolution of conflicts or problems developed in the articles under review. Of course, this can only be attempted in a limited number of cases, but such constructive presentation is very helpful and fully justifies the careful selection of authors by the editorial board. Noteworthy examples of this type are found in Eccles' discussion on conduction in nerve, Osgood's account of hæmoglobin formation and erythropoiesis, Wilhelmi's picture of the significance of hepatic anoxia in shock, Brobeck's attempt to harmonize the 'central' and 'gastric' components of hunger and Anderson's account of thyroid physiology.

The third potential of this publication, its international influence, is recognized by the editorial board in the preface. The board regrets the persistence of difficulties in obtaining contributions from a truly universal field, but affirms its intention to persist in its attempts to overcome these barriers. In this it must receive every encouragement from those who believe in scientific freedom.

A COMPARATIVE HISTOLOGY OF VERTEBRATES

Microscopic Anatomy of Vertebrates

By Prof. James I. Kendall. Third edition, thoroughly revised. Pp. 354. (London: Henry Kimpton, 1947.) 30*s.* net.

IT is a defect of the great majority of text-books of histology that, being intended chiefly for medical students, they wholly neglect all vertebrate classes except the mammals. As a result, students of zoology either learn no histology, or, being led into the subject by men whose interest is limited to one class, and even to one species, acquire a slight superficial knowledge with the same limitation. The book under review attempts to tackle the subject in a less limited manner. Inevitably, because of the vast preponderance of work done on mammals, it is heavily influenced by our knowledge of the microscopic anatomy of that class; but it is rich in descriptions of histological structures in other classes. Thus, the chapter on the integument deals with the skins of the dog-fish, of teleostean fishes, of the frog, reptiles, birds and mammals; that on excretory organs discusses separately the pronephric, mesonephric and metanephric kidneys, as illustrated in such animals as the hag-fish, the frog and the mammal.

Of course, no book of this kind, held within these limits of size, could satisfy every reviewer, and the present reviewer would have preferred greater emphasis on considerations of function and especially, where possible, on the functional differences correlated with differences of structure. On points of detail, one is made a little uneasy by finding the terms 'pre-cartilage', 'chondroid tissue' and 'pseudo-cartilage', used as synonyms. In the section on bone there does not seem to be any recognition of the existence of a microscopically homogeneous substance between the fibres, or of a distinction between lamellar and non-lamellar types of bone. The description of the dog-fish skin and placoid scale could well be revised, and the figure replaced; in the ganoid scale it is incorrect to describe the ganoin layer as "fibrous and uncalcified". In the paragraph on myogenic and neurogenic theories of heart-beat, statements are made which will lead students to believe that the elasmobranch heart is two-chambered and that of amphibians three-chambered.

The book is well illustrated with photomicrographs and diagrams, a number being new since the second edition. Some of the diagrams are rather crude, and one would have liked to see an illustration which would have made easier the identification of leucocytes in some laboratory animals below the mammalian level, especially of the Amphibia.

However, the reviewer, having done his duty by carping a little, would like to end: this is a good book, and it should be in every zoological library.

P. D. F. MURRAY

CYANOGEN COMPOUNDS

Cyanogen Compounds:

Their Chemistry, Detection and Estimation. By Herbert E. Williams. Second edition. Pp. xvi + 443. (London: Edward Arnold and Co., 1948.) 40*s.* net.

THE chemistry of the cyanogen compounds is one of the more difficult branches of the subject, and is one on which it is not easy to find collected information. The first edition of this book, published in 1915, served a very useful purpose in bringing together a large amount of information in a systematic form, and the new edition is necessary in view of the work which has appeared since that time. The treatment is practical, scarcely any space being given to theory, and in some cases this is a real defect of the book. The only formula for Prussian Blue is an old one which is incorrect, no notice being taken of recent work in this field which has cleared up much obscurity. Many of the formulæ given in all parts of the book are semi-empirical, and some account should have been taken of modern co-ordination formulæ for the compounds.

The treatment covers all that could be expected from the title, and a praiseworthy feature is the inclusion of many compounds which have not been investigated for a long time, some of which would, no doubt, repay new work and show interesting and useful properties. The chapters include the subjects of cyanogen and its derivatives, cyanamide, urea and related compounds, cyanates, cyanides, iron-cyanogen compounds, nitroferricyanides, thiocyanates, and five chapters on analysis, which are particularly noteworthy. References to literature are mostly given, and some patents are listed.

The book, taken as a whole, is good, and is one which should be found useful in the laboratory. The absence of an adequate theoretical background makes it essentially a work of reference. The reviewer noticed an unusually large number of errors in names, many of which appear also in the index: these include "Maequer" for Macquer, "Vanquelin" for Vauquelin, "Hautefeville" for Hautefeuille, "Blitz" for Biltz, etc. This creates a certain lack of confidence in the accuracy of the text. Some ordinary words also appear in unfamiliar forms:

"defraction" appears for diffraction, "tantallium" for tantalum, "turpin" for terpene, etc. Although the author claims that the full references will enable his often sketchy accounts to be extended, references are sometimes missing, as, for example, in the inadequate paragraph on cyanogen fluoride.

J. R. PARTINGTON

COLONIAL NATIONAL INCOMES

The Measurement of Colonial National Incomes

By Phyllis Deane. (National Institute of Economic and Social Research, Occasional Papers, No. 12.) Pp. xvi+173. (Cambridge: At the University Press, 1948.) 12*s*. 6*d*. net.

ONE of the most serious gaps in our knowledge of the Colonies has been the lack of adequate statistical analysis of their economic structures. True, there is much scattered statistical material, but it is not always easily accessible and little work has been done to bring it all together to form comprehensive surveys of the Colonial economies.

This book, of its kind a pioneer study, does much to fill this gap, in respect at any rate of three Colonial territories, and ably shows the possibilities as well as the difficulties of extending this work to other Colonies. The main objects of Miss Deane's study were, first, to discover by experiment the possibilities and limitations of applying to the Colonies the techniques evolved for the measurement of the national income of the United Kingdom; and secondly, to throw light on the economic structure and problems of the areas studied. For these purposes three Colonies were examined, Northern Rhodesia, Nyasaland and Jamaica, and their national incomes for the year 1938 calculated. As this inquiry had its beginnings in the early part of the War, 1938 was thought to be the most suitable year for which to make the calculation as there appeared to be relatively more material for that year than for other recent years. Nevertheless, it is impressed upon us throughout the study that the main limitation of all the calculations is lack of data. Moreover, the inquiry was carried out under all the difficulties of war-time London, without first-hand knowledge, by way of field-work, of the territories to which they relate, and therefore the results must be regarded as highly tentative and insufficient to "support firm conclusions on economic conditions in detail". It is the purpose of the research project, however, that the inquiry should be carried into the field.

Mention merely of two problems will serve to illustrate the difficulties that Miss Deane had to face. The first is that of measuring the national income of a territory where a large proportion of the inhabitants are wholly dependent, or nearly so, on subsistence farming; and secondly, the problems created by the existence of two races in one Colony, Africans and Europeans, the latter often with little degree of permanency, and where a significant proportion of the wealth created in the area in fact goes abroad in the form of profits, rents, interest and extra-colonial expenditures. That there are bound to be errors of calculation in the attempt to circumvent such problems with so little data is inevitable; the surprising fact is that the margins of error which Miss Deane has worked out for her calculations should be so small.

But even for those not versed in the finer points of statistical practice there is much that is revealing about the Colonies in the figures presented. In fact, at the end of her study Miss Deane suggests some of the more obvious ways in which the figures may be applied to bring out certain conspicuous features of Colonial economies, for example, the proportion of income that flows abroad from such territories, the distribution of income between Europeans and Africans, the industrial structure of the economies and so forth. Above all, for the purposes of planning Colonial economic development such figures are absolutely essential. Planning, to be successful, must be done in the light of its effect on total national income, its distribution, and on the channels by which it is spent. For purposes of Colonial development, therefore, we are going to need many more Colonial national income calculations such as the painstaking work Miss Deane has given us—and the sooner the better.

D. RANDAL WIGHTMAN

BIRD PICTURES

Fifty Prints

By Emerson Tuttle. With an Introduction by Chauncey Brewster Tinker, a Critique by Lewis E. York, and a Complete Catalogue from 1921 to 1946. Pp. xv + 21 + 50 plates. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1948.) 82*s*. 6*d*. net.

Wings in the Wilderness

By Allan D. Cruickshank. Pp. xiv + 125 + 125 plates. (New York and London: Oxford University Press, 1947.) 35*s*. net.

THE beauty of the bird, its elegance, its grace and its wonder of colouring have ever attracted the artist; note, for example, the prominence of the bird in Chinese and Japanese art. We have here two books dealing with bird portraits, in which the artistic theme is the predominant one; but the approach is from different angles, one being that of the etching and the other that of the camera.

The first mentioned is a collection of fifty prints by the late Emerson Tuttle. There are landscapes among them, but the greater part consist of portraits of birds, including many pictures of owls and hawks. Feather texture and bird character are remarkably delineated in these dry-points, the owls being especially satisfying, in particular the portrait of a snowy owl. The feathers are so soft and fluffy you feel as if you must stroke them. One mammal breaks the sequence, an alert and vigorous red squirrel.

In "Wings in the Wilderness" we have reproductions of 125 photographs from the camera of Mr. Allan Cruickshank, in which birds and birds only are portrayed, and as in the case of Mr. Tuttle's pictures, chiefly the birds of North America. We are accustomed to think that British bird photographers do well with their cameras; but this volume shows the high standard achieved by the ornithological camera users of the United States. Young birds, old birds, birds feeding young, birds swimming and birds in flight are portrayed with great skill. Among so many masterpieces of the camera, it is difficult to select pictures for particular praise; but the osprey on the wing is remarkably good and the wild turkey, a fine old gobbler, of especial interest. This is a book to interest everyone who has ever taken a snapshot of a bird.

FRANCES PITT

The Feeding of Farm Livestock

By J. C. B. Ellis. (Agricultural and Horticultural Series.) Second edition, revised. Pp. xiv+271+26 plates. (London: Crosby Lockwood and Son, Ltd., 1947.) 18s. net.

THE author's primary object has been to show how rations for any class of livestock may be constructed by the use of the Kellner starch equivalent system and protein-equivalents as measures for energy and protein requirements, and this object he has achieved in a smooth and satisfying manner. Like other books on the scientific feeding of farm animals, this volume conforms to the usual pattern, a preliminary explanation of the theoretical bases of scientific rationing being followed by a general description of feeding stuffs in common use, while in the latter chapters the principles of the rationing and management of the various classes of farm livestock are clearly and simply expounded. Following the experimental results of American investigators, the author has based the maintenance requirements for energy on the three-fourths power of the live-weight of the animal instead of on the usual surface law, and has also applied the same principle to the protein requirement estimations.

Owing to compression of material, the reader may be led falsely to assume that digested fat material is transported in the portal blood stream (p. 14), that ptyalin is present in the saliva of all animals (p. 13), and that metabolizable energy is the same as gross digestible energy (p. 23). There are also a few typographical and cross-indexing errors (pp. 1, 12, 214, 215 and 219). Apart from these minor faults, the book is attractively produced, the print is very readable, and the twenty-five photographic illustrations help materially to sustain the reader's interest.

E. T. HALNAN

Tables of Supersonic Flow Around Yawing Cones

By the Staff of the Computing Section, Center of Analysis, under the direction of Zdeněk Kopal. (Massachusetts Institute of Technology, Department of Electrical Engineering, Center of Analysis, Technical Report No. 3.) Pp. xviii + 321. (Cambridge, Mass.: Massachusetts Institute of Technology, 1947.) n.p.

THESE tables are prefaced by an account of the theory, which is based on work by Stone, hitherto unpublished. It is assumed that the motion is steady and isentropic along each streamline behind the shock wave, but not irrotational. The steady angle of yaw is taken to be a small quantity of the first order, and the equations for the first order perturbations of the known flow for zero yaw are worked out. Ultimately the solution is made to depend on a non-homogeneous ordinary differential equation of the second order. It appears that the shock wave is a circular cone the angle of yaw of which differs from that of the body.

Numerical integrations of the fundamental differential equation are the basis of the tables. The ratio of the specific heats for air is taken as 1·405 and the semi-apex angle of the cone ranges from 5° to 15° in steps of 2½°, and upward to 50° in steps of 5°. For each apex angle results are tabulated for equally spaced values of the ratio of the axial component of velocity at the surface to the velocity of escape into a vacuum. Consequently the Mach numbers, which are stated, show irregular increments.

W. J. DUNCAN

The Experimental Situation in Psychical Research

By S. G. Soal. (Being the Ninth Frederic W. H. Myers Memorial Lecture, 1947.) Pp. iv + 64 + 4 plates. (London: Society for Psychical Research, 1948.) 2s.

IN the ninth Frederic W. H. Myers Memorial Lecture, Dr. S. G. Soal has given an admirably succinct summary of the present situation as regards experimental psychical research, and has added a few short criticisms on the various attempts now being made to bring the phenomena of telepathy and telæsthesia under a rigid system of control. He describes his own experiments with Mr. Shackleton and Mrs. Stewart, briefly considers the various group experiments associated with the late Mr. Whately Carington, and has a few words to say on the Duke University series and the picture tests favoured by Dr. Hettinger.

From the results of his own work, Dr. Soal thinks that it is largely a waste of time to conduct mass experiments with unknown percipients unless it be with the view of discovering sensitives of marked ability. He prefers to concentrate attention on persons of promise and, if possible, develop the faculties so that they may become amenable to experimental procedure and the results to statistical analysis. Unfortunately, good subjects and trained experimenters are rare, so that the prospect of rapid progress does not appear to be bright. The technique for a repeatable experiment already exists; but for this to be successful the co-operation of a reliable subject must be obtained, and thus the search for such subjects must be considered to be of major importance.

Nairobi, Master Plan for a Colonial Capital

A Report prepared for the Municipal Council of Nairobi. By Prof. L. W. Thornton White, L. Silberman and P. R. Anderson. Pp. vii + 92. (London: H.M. Stationery Office, 1948.) 21s. net.

NAIROBI started in 1896 as a transport depot on a site that was none too favourable except for the railway which reached it three years later from the coast. Since then it has grown rapidly but largely without a plan, and now, with more than 100,000 inhabitants, is one of the largest inland towns of tropical Africa. The population is mixed, with Bantu Negroes in the majority; next in number Indians, and fewest, but in a dominating capacity, Europeans. At an altitude of 3,600 feet it has a climate suitable for Europeans and its centrality marks it out as the eventual capital of all European-held East Africa. At its present rate of growth it should reach nearly 300,000, which the authors think will be a desirable size about 1975, that is to say, if the serious problem of an adequate water supply can be solved. The rapid rise called for the planning and regulating of the town growth, and the present volume is the outcome of a careful study of the site and the functions of the town both at present and in the years to come. It was prepared at the instigation of the Municipal Council of Nairobi, by an architect, a civil engineer and a sociologist. The inclusion of the last in the team was a recognition that problems of race, caste and religion as well as purely material considerations had to be faced. The report not merely plans Nairobi for many years to come; it is also a discussion of the problems involved by Europe's introduction of the town and all it involves to the agricultural and pastoral peoples of tropical Africa.

OBSERVATIONS ON SLOW MESONS OF THE COSMIC RADIATION

By U. CAMERINI, H. MUIRHEAD
AND
DR. C. F. POWELL.
H. H. Wills Physical Laboratory, University of Bristol
AND
D. M. RITSON
Clarendon Laboratory, Oxford

Introduction

RECENT observations[1] have indicated that the slow negative mesons observed to be created in nuclear interactions taking place in photographic emulsions exposed to the cosmic radiation can produce disintegrations of both light and heavy nuclei. Both the modes of creation and extinction, of at least the majority of these particles, are therefore consistent with the assumption that they have a strong interaction with nucleons. In this paper we describe experiments which indicate that the negative mesons of mass $\sim 200\, m_e$ in the penetrating component of the cosmic radiation, even when captured by heavy atoms, rarely, and possibly never, produce disintegrations of nuclei with the emission of heavy charged particles.

The results also show that in experiments made near the ground, there is present, in addition to the downward stream of mesons of mass $\sim 200\, m_e$, an upward stream of similar particles with an intensity approximately half that of the downward component. These mesons are accompanied by σ- and π-mesons, and a comparison of the relative numbers of the different types allows us to make an estimate of the mean life-time, τ_π, of the heavy particles. The value thus obtained is $6 \pm 3 \times 10^{-9}$ sec.

Experimental Method

The present experiments were initiated as part of a series designed to determine the life-time of the different types of mesons present in the cosmic radiation. The main principle of the investigation was to observe the reduction in the number of heavy positive and negative mesons ($\sim 313\, m_e$), brought to rest in our emulsions after being generated in matter disposed around the plates, as the distance between the plates and the surrounding matter was increased.

As a first step in this programme, preliminary experiments were made at the Jungfraujoch with the simple arrangement shown in Fig. 1. We anticipated that the observations would allow us to determine the quantity of neighbouring matter which it would be necessary to employ in order to obtain a sufficient increase in the number of tracks of heavy mesons. In each case, twenty-four plates, Ilford Type *C2*, boron-loaded, 100 μ thick, in their original packing, were enclosed in a box of tinned iron (0·5 mm. thick), and supported 2 metres from the floor, and about 60 cm. below a light roof, with the surfaces of the emulsion lying in a vertical plane. In one case the plates were supported from the roof by strings; in the other they were placed on a light iron tripod, and surrounded on the four sides by lead blocks 5 cm. thick, the top and bottom of the assembly being left free.

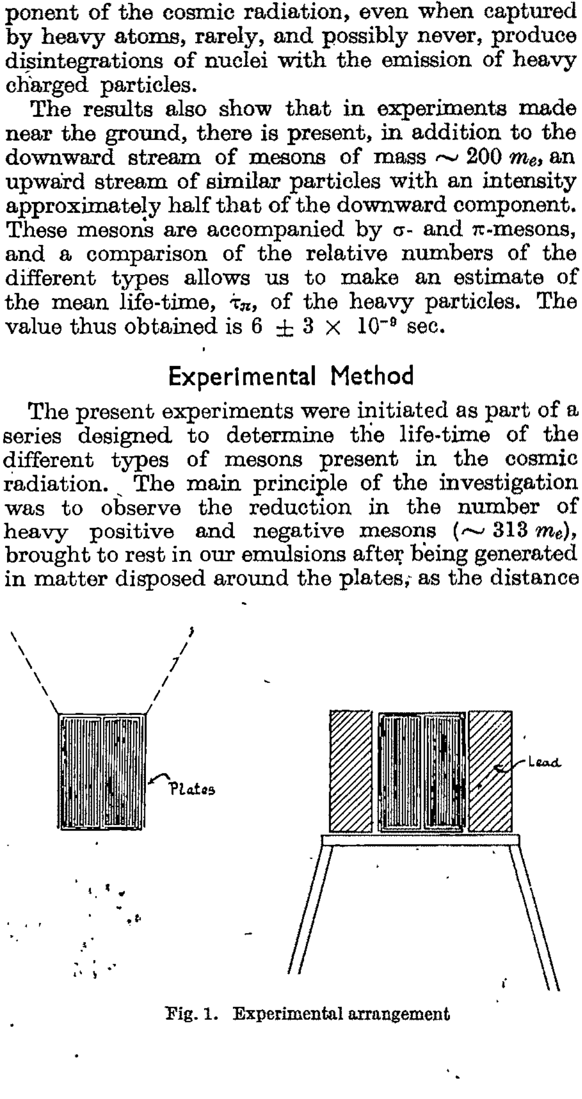

Fig. 1. Experimental arrangement

After an exposure of 35 days, the plates were marked so that their orientation during the exposure and their order in the assembly was known; and they were afterwards developed by the methods recently described[2]. The present results were obtained in the microscopic examination of 9·6 cm.^{3} of the emulsion of the plates thus obtained. In analysing the experimental results, we employ the classification for the different types of mesons given in an earlier paper[1]. The terms 'ρ-meson', 'σ-meson', etc., are employed for the different categories of mesons classified phenomenologically; and 'π-particle', 'μ-particle', when it is possible to distinguish particular types more precisely.

Angular Distribution of the ρ-Mesons

The directions of motion of the mesons, at their points of entry into the emulsion, were first determined. In every case, we chose to measure only the angle, relative to the vertical, of the projection of the track on the plane of the emulsion. The resulting angular distributions thus obtained, for ρ-mesons, are shown in Fig. 2*A*, the full lines corresponding to the measurements on the plates obtained without lead, curve *a*; and the dotted lines, to those obtained with lead, curve *b*.

It will be seen from Fig. 2*A* that, both in the experiments with and without lead, there is a pronounced downward flux of particles accompanied by an upward stream of about half the intensity; and that the numbers of particles in these directions are not appreciably influenced by the presence of the lead. The difference in the two distributions is given in Fig. 2*A*, curve *c*, and shows that a considerable number of ρ-mesons enter the plates in directions which indicate that they come from the lead.

We must anticipate that the Coulomb scattering in the plate assembly will cause the observed directions of motion to differ from those of the particles before they have been reduced to the relatively low speeds at which we can observe them. An analysis indicates, however, that these changes in direction are not serious, and that the original distribution must have been similar to that observed. Deviations become more frequent as the velocity of a particle is reduced, and we have therefore drawn the corresponding angular distributions for those particles of residual range greater than 300 μ. These are shown, in the form of a polar diagram, in Fig. 3, curves *a* and *b*, and display the same features as the results obtained by including the measurements made for

Curve (d) calculated original angular distribution unmodified by scattering; (e) estimated distribution to be observed in experiment without lead; (f) similar distribution with lead. Curves (e) and (f) are calculated for tracks greater than 300 μ

all mesons, irrespective of their residual range in the emulsion, curves c and d. It is a satisfactory feature that the pronounced 'waist' in the distribution without lead is accentuated when the results for the short tracks are excluded.

We have estimated the original distribution of the directions of motion of the mesons which stop in the plates, employing the scattering formulæ developed by E. J. Williams, and the result is shown in Fig. 2B, curve d. Owing to scattering in the plates, such an original distribution should appear in the experiments without lead like that shown in curve e of the same figure; and, in the experiment with lead, as curve f.

The estimated original angular distribution of the downward flux of mesons appears to be in reasonable agreement with the measurements, made by Greisen[3], with a counter telescope, on the mixed stream of electrons and slow mesons which form the soft component of the cosmic radiation.

As a step towards calculating the absolute intensity of the mesons, we have plotted the distribution in range of the observed particles. In agreement with the previous results[4], the observations show that the observers record the mesons, of which the length of the projection of the track is greater than 200 μ, with constant efficiency. Further, the consistency between the results of two observers, obtained in the examination of the same plate, shows that this efficiency is close to unity. The absolute intensity, $I\rho(\theta)$, the number of ρ-mesons per c.c. per unit solid angle per

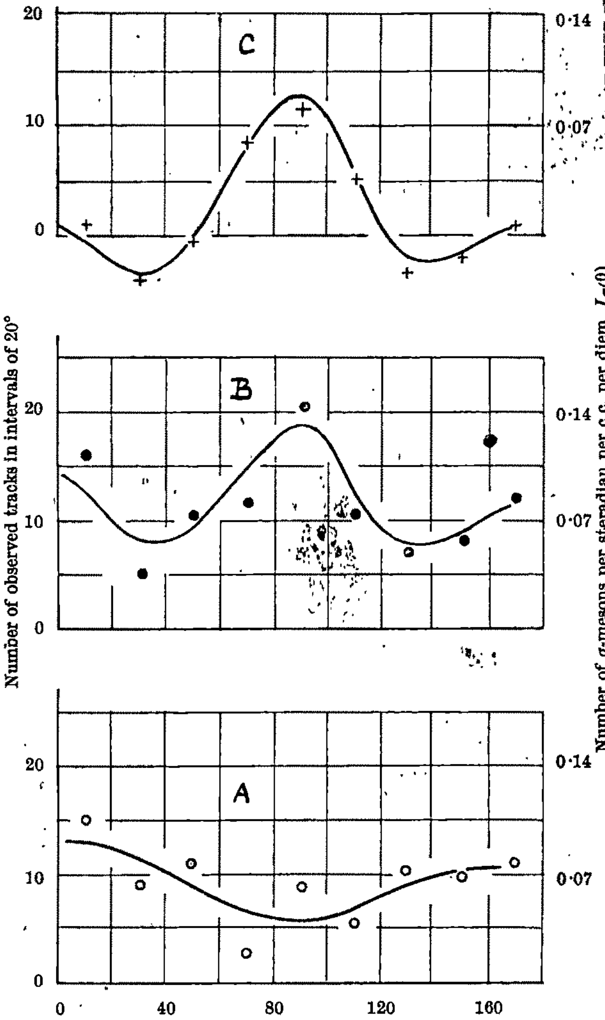

Fig. 4. Angular distribution of σ-mesons. (*A*) Without lead (*B*) with lead; and (*C*) difference (*B*)–(*A*)

diem, has been calculated, therefore, from the numbers of tracks of which the projections are greater than 200 μ, using a procedure similar to that described in a previous paper[4]. This has allowed us to insert a scale of absolute intensity in Figs. 2 and 4.

Angular Distribution of σ-Mesons

The number of tracks of σ-mesons in the volume of the emulsions examined hitherto is much smaller than that for the ρ-mesons, so that the statistical fluctuations are more serious. The results are shown in Fig. 4, *A* and *B*, for the exposures with and without lead. It will be seen that the addition of the lead results in a considerable increase in the number of σ-mesons and that these enter the emulsions in directions which indicate that they have originated in the lead. In Fig. 4*C*, we plot the difference in the two distributions. Although the standard deviations associated with each of the points in this figure are relatively large, so that the small departures of the points from the smooth curve drawn through them must be regarded as fortuitous, Fig. 4*C* gives good evidence for the existence of a pronounced lateral stream of σ-mesons, produced by the presence of the lead.

Interpretation of Observed Angular Distributions

The above observations can be interpreted in terms of the relations of the mesons of different types, outlined in the previous paper. We regard the downward stream of ρ-mesons as corresponding to the particles of the penetrating component of the cosmic rays, which originate by the decay in flight of π^+- and π^--particles formed in the atmosphere.

Strong support for the view that the particles in the main downward stream observed in the present experiments are identical with the mesons of the penetrating component is provided by a comparison of our results with the observations of Rossi, Sands and Sard[5]. These workers have investigated the rate of arrival of slow mesons with a life-time of 2·2 μsec., using a delayed coincidence method, at an altitude of 14,000 ft. We have recalculated their results on the assumption that the energy of the electrons formed by the decay of the mesons is 25 MeV., as suggested by the recent experiments of Anderson and his colleagues[6]. The values so obtained can be compared with the rate of arrival of mesons in our emulsions from all directions in the upper hemisphere. The two values are thus found to agree to within 30 per cent (see Table 2).

Table 1

Ratio of the integrals, $N = \int I(\theta).d\theta$, for different intervals of the angle θ. $I(\theta)$ = the intensity per steradian per cm.³ per diem, at the Jungfraujoch, 11,000 ft.

Interval in θ°	With lead		Without lead	
	$N_\sigma/N_\rho \times 10^{-2}$	$N_\pi/N_\rho \times 10^{-2}$	$N_\sigma/N_\rho \times 10^{-2}$	$N_\pi/N_\rho \times 10^{-2}$
0– 40	5·0 ± 1·3	3·5 ± 2·1	5·8 ± 1·5	3·5 ± 2·1
60–120	21·0 ± 3·6	18·1 ± 6·8	9·2 ± 2·5	12·0 ± 6·0
140–180	7·2 ± 2·1	16·7 ± 6·7	11·5 ± 2·6	6·6 ± 4·1

Table 2

Values of the total integrated intensity, $J^\pi = \int_0^\pi I(\theta).\sin\theta.d\theta$ in mesons per cm.³ of the emulsion per diem, for different classes of mesons, at the Jungfraujoch, 11,000 ft.

	J_ρ	J_σ	J_π
With lead	8·42 ± 0·48	1·09 ± 0·14	1·04 ± 0·35
Without lead ..	7·59 ± 0·46	0·74 ± 0·11	0·68 ± 0·23
Mean values ..	8·0 ± 0·3	0·9 ± 0·1	0·9 ± 0·2

For ρ-mesons, in the exposures made without lead, the total intensity in the upper hemisphere, $J^{\pi/2}$, is 4·1 mesons per cm.³ per diem. The calculated value, based on the experiments of Rossi, is found to be ∼3 mesons per cm.³ per diem, assuming the decay electron to have an energy of 25 MeV.

We attribute the difference in the two distributions of the ρ-mesons, observed in the exposures with and without lead, to the particles in the main downward stream which have been scattered into the plates in traversing the surrounding lead. A comparison of the calculated curves Fig. 2*B*, curves *e* and *f*, with the corresponding experimental results represented in the accompanying diagram, 2*A*, shows that we can thus account for at least a large part of the increased number of ρ-mesons. We cannot, however, exclude the possibility that some of them are due to particles which have been created in the lead.

The form of the distribution in angle of the σ-mesons, in the exposure made without lead, is similar to that of the corresponding curve for ρ-mesons. We attribute the lateral stream of σ-mesons, produced by the addition of matter around the plates, to negative mesons produced in the lead which have not had time to decay in flight. The distribution in angle of these mesons is consistent with this assumption. The presence of the lead also gives rise to an increase in the number of π-mesons, but in this case, because of the low probability of observing these particles[4], the numbers are too small to allow any conclusions to be drawn regarding their distribution in angle.

Nature of the ρ-Mesons in the Upward Stream

If we apply a similar analysis to the meson stream arising from the matter beneath the plate assembly, we find that the ratio of the numbers of ρ- to σ-mesons is about half as great as that observed in the main downward stream (see Table 1). It seems reasonable to suppose that the ρ-mesons are in this case, also, composed mainly of μ^+- and μ^--particles, formed by decay in flight; and that in spite of the relatively close proximity of the matter in which the parent π-particles are produced, only a small fraction of them reaches the emulsion before they have decayed.

Comparison of the Number of ρ- and σ-Mesons in the Downward Stream

It is of great interest to compare the downward intensity, $I_\rho(\theta)$, of the ρ-mesons, measured in mesons per steradian per cm.^{3} per diem, with the corresponding quantity for σ-mesons, $I_\sigma(\theta)$. The estimated number of ρ-mesons entering our plates, in the angular range 0–40° with the vertical, $N_\rho{}^{40°} = \int_0^{40°} I(\theta)\,.\,d\theta$, is 0·86 ± 0·07 per cm.^{3} per diem. The corresponding value for the σ-mesons, $N_\sigma{}^{40°}$, is 0·05 ± 0·01.

Reference was made in the previous paper to recent observations on the sign of the charge of the ρ-mesons, using the method of magnetic deflexion, by which it was shown that approximately half these particles are negatively charged. This result is in accord with magnetic deflexion experiments made with expansion chambers on cosmic ray mesons[7]. In order to allow for a small positive excess, and for the presence among the ρ-mesons of some π-mesons of which we fail to distinguish the tracks of the associated μ-mesons, we shall assume that 40 per cent of the ρ-mesons are negatively charged. It follows that the number of negative ρ-mesons in the downward stream (0–40°) is 0·34 ± 0·03 per cm.^{3} per diem.

Of all the negative mesons in the downward stream, a certain fraction, f, will be stopped in silver bromide grains and will be captured by atoms of high atomic number; and the remainder, $1-f$, will be brought to rest in gelatine. Through the kindness of Dr. Gardner and Mr. Lattes, two of us (U. C. and H. M.) have recently obtained plates exposed to the negative mesons generated artificially at Berkeley. The emulsions of these plates were made up of alternate layers of normal emulsion and of pure gelatine. It was thus possible to study the difference in behaviour of the mesons stopped in gelatine, and of those stopped in the mixture of gelatine and silver bromide composing the ordinary emulsion. Among other features, the observations made it possible to show that the fraction, f, of negative mesons stopping in a normal emulsion which are captured by heavy atoms is greater than 0·3. Theoretical estimates of the stopping power of the different constituents of the emulsion give values lying between 0·4 and 0·6, and we shall assume that $f = 0{\cdot}5$.

It is known, from the delayed coincidence experiments, that most of the negative mesons of the cosmic rays, of which the life-time is 2·2 μsec., undergo normal decay with the emission of an electron, when brought to rest in light elements. We shall therefore not expect to observe disintegrations produced by those of the μ-mesons, whether positively or negatively charged, which stop in the gelatine of the emulsion; and we confine our attention to those negative mesons which stop in silver bromide.

Let us assume tentatively that all the σ-mesons in the downward stream are μ^--particles. We must then conclude that the number of μ^--particles which produce observable disintegrations, in comparison with the total number of ρ-mesons, is less than 6 per cent (Table 1). Further, if 40 per cent of the ρ-mesons are μ^--particles, it follows that only 15 per cent of the latter produce observed disintegrations. Taking $f = 0{\cdot}5$, we conclude that only 30 per cent of the μ^--particles which stop in silver bromide produce observable disintegrations.

The above values must represent upper limits, for a certain fraction, φ, of the σ-mesons must be heavy particles with a strong interaction with nucleons. There is good evidence that φ is nearly equal to unity. Thus we can compare the intensity of σ-mesons in the downward stream, $N_\sigma{}^{40°}$, with that of π-mesons in the same angular range, $N_\pi{}^{40°}$. The numbers so obtained are $N_\sigma{}^{40°} = 0{\cdot}054 \pm 0{\cdot}010$ and $N_\pi{}^{40°} = 0{\cdot}035 \pm 0{\cdot}015$. The corresponding numbers for the complete angular range are $N_\sigma = 0{\cdot}20 \pm 0{\cdot}03$ and $N_\pi = 0{\cdot}16 \pm 0{\cdot}03$. It is therefore reasonable to assume that the positively charged π-mesons, π^+, and the negatively charged heavy particles, $\pi^-(313\, m_e)$, are produced in approximately equal numbers. We should then have to regard at least the great majority of the σ-mesons in the main downward stream as particles with a strong interaction with nucleons probably produced in the roof and other neighbouring matter above the plates, for they are accompanied by π-mesons in approximately equal numbers.

Thus suppose we take the values for the number of σ- and π-mesons in the downward stream (0–40°), from the experiments both with and without lead, and assume that the number of σ-mesons, with a strong interaction, π^-, is equal to the number of π-mesons, π^+. We can then write:

$$\frac{N_\sigma(\mu^-)}{N_\rho} = \frac{N_\sigma}{N_\rho} - \frac{N_\pi}{N_\rho}.$$

Using the values given in Table 1, we thus find:

$$\frac{N_\sigma(\mu^-)}{N_\rho} = 1{\cdot}9 \pm 1{\cdot}8 \text{ per cent.}$$

Assuming, as above, that 40 per cent of the ρ-mesons are μ^--particles, it follows that only 9·5 ± 9·0 per cent of them, which stop in silver bromide, produce observable disintegrations. The results, therefore, show that most, and possibly all, the light negative mesons of the penetrating component of mass $\sim 200\, m_e$ fail to lead to a nuclear disintegration with the emission of protons and other heavy charged particles, when stopped in silver bromide.

This result depends on estimates of quantities which are not known with precision; but even if we choose the most unfavourable values, we are still led to substantially the same conclusion. Thus assume that the proportion of negatively charged particles among the ρ-mesons is only 30 per cent; and that all the

σ-mesons in the downward stream are due to μ^--particles, none being attributed to π^--particles generated in the plates and in local matter. Even with these assumptions, both of which it would be difficult to support, we must conclude that 60 per cent of the light negative mesons of the cosmic radiation, when stopped in materials of high atomic number, produce no nuclear disintegrations with the emission of heavy charged particles.

The correctness of the assumption that the numbers of positively and negatively charged ρ-mesons are approximately equal (that $\rho^+/\rho^- \sim 2\cdot 0$, or less) has been supported by reference to the results of experiments on the penetrating component[7]. It might be objected that, in order to reduce the intensity of the soft component, these experiments are commonly made under considerable thickness of absorbing materials; and that there is no guarantee that the small values for the positive excess which are thus found will also occur under a light roof. This appears to be the weakest point in the interpretation of our results. While the preliminary measurements by the magnetic deflexion method indicate that the positive excess is, in fact, small, it is important to continue the observations in order to increase their statistical weight. It would, however, be very difficult to account for any great positive excess in terms of our present views on the nature of the processes which lead to the production of the different classes of mesons, and our conclusions would not be seriously modified if the ratio μ^+/μ^- were as great as 2.

Marshak[9] and others have considered the possibility that the interaction of a light negative meson with a nucleus may lead to the emission of a neutretto; and that the ejection of heavy charged particles from the nucleus as a result of the interaction is never, or only rarely, to be expected. Further, recent experiments[10] indicate that the capture of these mesons by lead atoms results in the emission of neutrons from the nuclei, a result which is consistent with the view that the meson interacts with one of the protons in the nucleus, as represented by the equation: $H^1 + \mu^{-1} \rightarrow n^\circ + \nu^\circ$, where ν° denotes the neutretto. Such an assumption allows us to account for the absence of the emission of heavy charged particles as a result of the interaction, for the total release of energy to be accounted for is reduced by the amount corresponding to the rest-mass of the neutretto; and it is perhaps reasonable to assume, from the principle of the conservation of momentum, that most of the balance of energy will appear as kinetic energy of the neutretto. In any case, it appears to be certain that if a light negative meson is captured by a nucleus, only a small fraction of the energy liberated by the disappearance of its rest-mass is distributed among the nucleons.

The Life-time of the π-Particles

Recently, the results of experiments on the intensity of the penetrating component of the cosmic radiation at great depths underground have been employed to obtain an estimate of the mean life-time of the heavy mesons, τ_π, and the value so obtained is 6×10^{-8} sec.[11]. The present experiments have allowed us, however, to make an independent estimate of this quantity, and we have found a much smaller value, namely, $\sim 6 \times 10^{-9}$ sec.

The new estimate is based on the following considerations: We have attributed the upward stream of ρ-mesons to μ^+- and μ^--particles formed by the decay in flight of upward moving π^+- and π^--particles which have been generated in the matter beneath the plate assembly. By comparing the number of ρ-mesons in the upward stream with that of the π-particles which have escaped decay; and by estimating the time of flight of the particles, in moving from their points of origin to the plate assembly, we can calculate the life-time of the heavy mesons.

This method depends for its success on the correctness of the assumption that the majority of the ρ-mesons in the upward moving stream are produced by the decay of π-particles; and that not more than a small proportion of them are generated directly in nuclear interactions. This view is supported by the results of the previous paper[1] which suggest that the number of μ-particles directly produced is small compared with the corresponding number of π-particles; but in order to obtain a further check, we have examined plates exposed in the ice of a glacier. In such plates, an upward moving stream of mesons can be detected, but it is now found to be composed of π-particles and ρ-mesons in roughly equal numbers. This observation proves that the number of ρ-mesons directly produced is less than that of the π-particles. We show, afterwards, that we can account for the ρ-mesons, in this case also, by decay in flight of π-particles.

In calculating the life-time, we require to know the distribution of the matter beneath the plates. The floor immediately beneath the assembly is composed of layers of various materials—granite, reinforced concrete, cork and wood—with a total weight of ~ 100 gm. per cm.^{2}. Beneath this is a number of rooms, one above the other, 2·5 m. high, with floors of weight ~ 80 gm. per cm.^{2}.

The mesons forming the upward stream are found to reach the end of their range at points which are distributed uniformly throughout the emulsions; and the energy at the point of entry into the assembly, of a meson which comes to rest in the central regions of the plates, is about 35 MeV. We therefore assume, as a first approximation, that the mesons originate in the central layers of the first floor, and come to rest in the centre of the plates; that none of the π-particles is locally produced in the plate assembly itself; and that 90 per cent of the ρ-mesons in the upward stream are μ^+- and μ^--particles.

With these assumptions we find

$$\tau_\pi = 5 \times 10^{-9} \text{ sec.}$$

We have made a more precise analysis, in which account is taken both of the generation of the mesons at different depths in the floor; and of the difference in energy, at the points of entry into the plate assembly, of those mesons which stop in different regions of the plates. This leads to substantially the same value, namely,

$$\tau_\pi = 6 \times 10^{-9} \text{ sec.}$$

It may be objected that a considerable proportion of the upward stream of mesons could have been generated at greater depths; in the lower floors of the building, for example. Such mesons must, however, have sufficient energy to penetrate the floors above their points of creation, in order to reach the plates. As a result, the relativistic contraction of the time-scale begins to play an important part. If, for example, we assume that all the mesons have been generated in the second floor, we find the following value for the life-time:

$$\tau_\pi = 7 \times 10^{-9} \text{ sec.}$$

and if generated in the third floor:

$$\tau_\pi = 8 \times 10^{-9} \text{ sec.}$$

The calculated values of τ_π are therefore rather insensitive to the assumed range of the 'primary' radiation. We take as the best value $\tau_\pi = 6 \times 10^{-9}$ sec., corresponding to the assumption that the 'primary' radiation is reduced to an intensity $1/e$ of its original value in traversing 50 cm. of concrete. It appears reasonable to assume that the contribution to the observed backward stream made by the mesons generated in the lower floors will be relatively unimportant not only because of the absorption of the primary radiation by the overlying matter, but also because there will be a tendency for the mesons to be thrown forward in the direction of the motion of the primary radiation as their energy of emission increases.

Apart from these uncertainties, the above values must be regarded as upper limits, for some of the observed π- and σ-mesons, in the angular interval under consideration (140°–180°), will have originated in processes taking place in the plate assembly itself. Assuming that 0·03 mesons per steradian per cm.^3 per diem are produced in this way, the calculated values of τ_π are reduced by about 30 per cent.

Returning now to the consideration of the exposures made on the glacier, it is found possible, using the calculated value of τ_π, to account for the presence of ρ-mesons in the backward stream, in spite of the much greater proximity to the plates of the matter in which the mesons are generated. The ice, which may be regarded as of indefinitely great extent, contributes a stream of π-particles with an intensity two or three times as great as that produced by the lead. It is therefore reasonable to assume that the effective thickness of the producing layer of ice, which contributes to the σ- and π-mesons stopping in the plates, is at least 110 cm. Calculations indicate that the relative numbers of π- and μ-particles observed are in agreement with a lifetime of 6×10^{-9} sec. The observations are thus consistent, in this respect also, with the assumed absence of the direct generation of μ-particles.

Alternatively, by combining the results of the two experiments—that made in the glacier, and that with the plates supported 2 m. above the floor—it is possible to obtain the following limits to the value of the life-time, without assuming that the μ-particles are not produced directly:

$$3 \times 10^{-9} \text{ sec.} < \tau_\pi < 1\cdot5 \times 10^{-8} \text{ sec.}$$

We believe, however, that the π-particles are alone produced directly, and if this is correct our results indicate that

$$\tau_\pi = 6 \pm 3 \times 10^{-9} \text{ sec.}$$

The present experiments were designed only as a preliminary step towards determining the life-time of the heavy mesons, and the possibility of making the present estimates only appeared during the course of the investigation. Further experiments, using a more favourable geometrical disposition, are now in progress.

Summary

The main conclusions which follow from our results may be summarized in the following terms:

(1) Observations have been made on the directions of motion, of mesons recorded by photographic plates exposed to the cosmic radiation, at their points of entry into the emulsion. The results show that there is a pronounced downward stream of ρ-mesons. The rate of arrival of these particles, and the estimated original distribution in angle of their directions of motion, before they have been scattered in the plate assembly, show that most of them are identical with the mesons of the penetrating component of the cosmic rays.

(2) Near the surface of the earth, in addition to the downward stream of mesons of mass $\sim 200\, m_e$, there is an upward stream of similar particles of considerable intensity. These particles may be regarded as being formed by the decay in flight of those π^+- and π^--particles, generated in the matter beneath the plate assembly, which are ejected upwards.

(3) Less than 15 per cent of the light negative mesons of the cosmic radiation, when brought to rest in the emulsion, produce nuclear disintegrations with the emission of heavy charged particles. It appears to be necessary, therefore, to attribute the failure to observe electrons arising from the decay of these particles, when they are stopped in materials of high atomic number, to other causes. While the results do not preclude the possibility that mesons of this type sometimes produce observable disintegrations, the low value of the upper limit for the fraction which do so, leads to a strong presupposition that they always disappear through processes of another type. Taken in conjunction with the results of other experiments, our observations give support to the view that the capture of the meson leads to the emission of a neutron and a neutretto.

(4) By comparing the relative numbers of the π- and μ-particles in the upward flux of mesons, it is possible to make an estimate of the mean life-time of the heavy mesons. Assuming that the μ-particles are not directly produced in nuclear interactions, the value thus obtained is $\tau_\pi = 6 \pm 3 \times 10^{-9}$ sec.

WE are greatly indebted to Mr. G. R. de Salis for assistance in making the exposures at the Jungfraujoch; to Dr. C. Franzinetti and Dr. S. Rosenblum for kindly making available to us the preliminary results of their experiments on the determination of the sign of the charge of the ρ-mesons; to Mr. C. M. G. Lattes and Dr. E. Gardner for the plates exposed to the mesons produced by the Berkeley 180-in. cyclotron; and to Prof. von Muralt, director of the Hochalpine Forschungsstation Jungfraujoch, for assistance and kind hospitality. The plates exposed on the glacier were obtained in a collaboration between Mr. Y. Goldschmidt-Clermont, of the Centre Physique Nucléaire, Brussels, and three of us (U. C., H. M. and D. M.), for the purpose of determining the absorption in ice of the radiation responsible for the production of 'stars'. A full account of these experiments will be published shortly elsewhere.

THE HUMAN MILK BANK

By EDITH G. DARE, O.B.E.

Formerly Matron of Queen Charlotte's Hospital, London

[The first Human Milk Bank in Great Britain was established at Queen Charlotte's Hospital, London, in 1938, through the initiative and under the expert guidance of Miss Edith Dare, then the matron, with the financial assistance of the late Sir Julian Cahn through the National Birthday Trust Fund. This Bank followed closely on the heels of similar banks and bureaux in the United States (which Miss Dare visited in order to study their organisation, equipment and method of working), Germany and the U.S.S.R. The author has recently retired from her post as matron of the Hospital which she has held with distinction for twenty-eight years (she has been connected with the Hospital since 1911); but she still retains an active interest in the Human Milk Bank based at the Hospital as honorary director of the former for life. In the following article she describes the founding of the Bank, and reviews the advances made there and elsewhere since its inception.—EDITORS.]

THE Human Milk Bank at Queen Charlotte's Hospital, London, was founded in 1938—the first of its kind to be established in Great Britain. By its means, the lives of many sick babies have been saved and others have been safely brought to normal especially by supplementing the mothers' milk and assisting during periods of crisis.

Having visited several such banks and bureaux in the United States during 1938, I soon became convinced that here was a valuable social and medical service that neither Great Britain nor any other country could afford to ignore. Such a service should be established, at any rate in Great Britain, without delay. At the inception of this, the first, Bank, it was necessary to obtain funds; these were soon forthcoming from the National Birthday Trust Fund, through the generosity of the late Sir Julian Cahn. To-day, however, the Bank has succeeded in becoming entirely self-supporting; indeed it is paying its own way with a reasonably safe margin. The leading pædiatricians keenly support it; in fact, they look upon it already as an essential part of the social services of the country, especially since it is recognized by physiologists that no food other than human milk is suitable during the neo-natal period. The premature baby, the sick baby, operation cases all can benefit from the human milk so supplied. As pointed out by Dr. Martha Dynski-Klein, the "incidence of infection in infancy is estimated to be twice as high in artificially fed babies as in breast-fed ones, and the death-rate ten times as high"[1].

At the Queen Charlotte's Hospital the milk is obtained mainly from women who have been patients in the Hospital, though other women also come forward. The surplus milk is withdrawn, either by means of a breast pump, which the mother learns to manipulate herself, or manual expression is used. The mother gathers her surplus milk into a sterilized bottle which is kept in an ice box, both of which are supplied by the Bank. This is collected daily by a member of the staff of the Bank. All equipment, including sterilized towels, dishes, etc., are also supplied. Most of the donors are paid for their services.

All the surplus milk thus collected from nursing mothers (now returned to their homes) is taken to the clinic and there strained and mixed, after it has passed exacting chemical and bacterial tests. Though human milk varies somewhat in chemical content, especially in proteins and lactose, the resulting mixture has been proved to be quite satisfactory for any baby. From the mixer the milk is bottled, and then the bottles are placed in pasteurization tanks. Later, they are labelled and put into refrigerators where they are kept until required. The milk can be, and is, sent to many parts of the country, where it is required, either by special vans or train (in the latter case, special arrangements have been made for express delivery); on certain occasions even the aeroplane has been pressed into service. Queen Charlotte's Milk Bank supplies several of the leading London and provincial hospitals. A charge is usually made for the service, both to the hospitals and to individual patients; but where there is financial hardship the service is free.

To meet acute emergencies some milk is 'quick frozen' in order that it may be stored for an indefinite length of time. For this purpose 'dry ice' is used. Special moulds are placed over the 'dry ice'; into these moulds the milk is placed by means of a sterilized syringe. Another block of 'dry ice' is placed over the filled moulds, and the milk left for about two minutes to freeze. Then the disks of frozen milk are removed under aseptic conditions and kept in refrigerators until required. Such milk will keep almost indefinitely at about −10° F. Milk not thus treated, that is, milk which has been placed in the refrigerator immediately after pasteurization, will last for about forty-eight hours only. Milk which is to be 'quick frozen' must be quite fresh, that is, it must have been withdrawn from the mother on the same day that it is to be frozen.

Dr. Dynski-Klein[1] has shown by the following data that human milk which is boiled before quick cooling shows only little effective change in content, and no viable bacteria are present.

	Before boiling	After boiling
Protein	1·8–2·2 gm./100 ml.	1·5–3·0 gm./100 ml.
Fat	2·7–4·6 ,,	3·0–0·0 ,,
Lactose	5·7–6·5 ,,	6·2–7·3 ,,
Vitamin C	3·9–4·6 mgm./100 ml.	3·0–7·3 mgm./100 ml.

At her clinic, Dr. Dynski-Klein administers ascorbic acid to premature and sick babies.

The staff at Queen Charlotte's Hospital, who carry out the work of the Bank, comprise two specially trained sisters. It is their responsibility to collect milk from the mothers in their homes (two motor-cars are supplied for the purpose), and to carry out the entire routine of testing (except bacterial and chemical, which is done by an outside laboratory, which specializes in milk testing), pasteurizing, sterilizing and storing at the clinic. As much as eighteen gallons of milk have been dealt with in one week in this way. The staff, equipment and costs of a human milk bank is therefore not prohibitive considering its very wide scope, its great potentialities and its consequent importance to public health and service. To-day the Bank at Queen Charlotte's Hospital has its own Board of Governors, of which the Lord Chancellor, Viscount Jowitt, is the chairman.

There seems to be little room for doubt that the establishment of human milk banks throughout the country, organised on a county or some other regional basis, should be treated as a social and medical service of prime importance. The pioneer work done at Queen Charlotte's Hospital has now expanded so substantially as to provide a complete pilot plant or type specimen for the guidance of future banks. The space required is not great, and the staffing and other problems are of not considerable magnitude. Indeed, a human bank has already been established at Cardiff; there is a smaller unit at Manchester; another is being formed in Birmingham. There are other milk bureaux, which are usually centred in hospitals, but their services are confined to the hospital patients themselves; that is, though the human milk is obtained from mothers both within and without the hospital, it is given only to babies in the maternity wards of that hospital; and if there is any left over it is sent to the children's wards.

But much remains to be done, for even now, banks and bureaux are adversely affected by the inconstancy of supply, depending as the supply does on propaganda and the efficiency and cleanliness of the donors, to say nothing of their goodwill. Now that the National Health Service Act is in force, there are already hospital regions which might well form the necessary units on which to base new human milk banks. This point well might be considered in view of the possibility that if such banks are established over the entire country they will eventually come under the charge of the Ministry of Health through its regional or local authorities now set up under the Act.

[1] *Brit. Med. J.*, 258 (Aug. 24, 1946).

THE BRITISH GAS INDUSTRY

THE eighty-fifth annual meeting of the Institution of Gas Engineers was held in London during June 8–11 under the presidency of Dr. Harold Hartley. It was a notable event in its history, being probably the last before the gas industry becomes integrated on a regional basis. Dr. Hartley reviewed the rise of the industry—the pioneer in the practice of distributing fuel and power as a public utility. He initiated a stocktaking of the present position and surveyed the prospects of the future. The papers presented for discussion centred round these themes. In the past, the industry experienced the advantages of competition as a stimulus to progress, not without the disadvantages of a multiplicity of independent local undertakings. For many years the need for reorganisation had been recognized. Progress in this direction had been made—some people had thought not rapidly enough. In 1943 a report of the Post-War Planning Committee of the British Gas Federation proposed geographical integration of its undertakings. This concept was eventually endorsed by the Heyworth Committee of the Government of the time. Since then the Government has decided that the desired end shall be attained by nationalization, and the necessary legislation is now before Parliament.

One cannot assess usefully the gas industry, or rather the industry of coal carbonization, apart from the supply and utilization of coal. Never was the efficiency of utilization and conservation of reserves so important. Formerly, when coal was cheap judged by present standards, and freely available, it was used as though future supplies faced no limit. Often little attention, either domestic or industrial, was paid to matters of efficiency or expenditure of labour in use. To-day the struggle to raise adequate supplies of coal to the surface is continuous. Adequacy has come to take priority over cost. One of the most effective means of meeting scarcity is to practice efficiency in use—a means promoted by the Ministry of Fuel and Power since its formation. The problems of scarcity create the most serious difficulties for public utilities, which undertake to maintain an adequate supply of a manufactured product liable to extreme and daily peaks of demand. The shortage of plant has created difficulties of a national scope for the electrical industry, difficulties only met by the shedding of load. Peak loads occur weekly in the consumption of gas; but these, owing to difference in conditions of distribution, pass almost unnoticed. To-day a new factor has come into prominence owing to the need for maintaining exports of coal. Formerly the export of coal was one only of the ample means of balancing the national budget in Britain. Now it is an indispensable means for maintaining national and international policy.

Export now obtains priority in the supply of coal, and even for the higher grades of coal. The loss of our higher grade coal—especially the best coking coal—is regrettable, although apparently inevitable at present. From the long-term point of view the consequences may be disastrous.

Every circumstance points to the need for promoting the conservation of fuel, and scrutinizing industrial practices to see how far policy or practice conforms to this need. From this point of view the papers presented at the Institute's meeting are timely. T. C. Finlayson and F. S. Townend examined critically the types of plant available to provide the supplies of coke and gas in relation to seasonal needs. Seasonal variations play a vital part in the organisation of public utilities. The gas industry requires to control the ratio of coke to gas production according to supply and consumption; but existing means to this end are only partially effective. The usual method is based on the gasification of oil, but now this is no longer adequate. Whatever the future productivity of the oil-fields, at present there is a shortage. The complete gasification of coal might make a valuable contribution to the necessary control of coke-gas ratio of production. A measure of success has been realized in Germany with the complete gasification of lignite under pressure; but so far the use of British bituminous coal has not proved serviceable. These authors conclude that "it is difficult to envisage this process as producing a therm of gas substantially cheaper than that obtained by existing methods provided that the coke can be sold". In short, there is still no certainty that costs will allow complete gasification to displace existing methods of carbonization. Linked with complete gasification of coal is the problem of distribution required to provide the 'whole-house' domestic service which is a present ideal. This might involve a tenfold increase of supply per dwelling. H. J. Escreet's survey of gas distribution is intended to examine current practice and experience with the view of finding the answer. Cost, he said, need not exceed present figures. There would, however, be a loss of the convenience given by the presence of stocks of solid fuel already distributed to meet the seasonal peak of demand for fuel. The fact is that the gas supply is a two-fuel industry, able to supply both solid and fluid fuel, and thus enjoys a unique position for dealing with the fluctuations of load caused by the British climate. If the two-fuel system persists, it points to the need for attention to the improvement of manufactured smokeless fuels and consequent conservation of high-grade coking coals.

Other papers dealt with ancillary subjects—availability of British gas coals, purification and marketing of gas and administration. At a time when everything points to the need for conserving coal and promoting efficiency in its use, the series of papers makes a valuable compilation.

H. J. HODSMAN

THE BALANCE OF RESEARCH AND TEACHING AT UNIVERSITIES

ONE session at the sixth Congress of the Universities of the Commonwealth, which was held in Oxford during July 19–23, was devoted to what is perhaps the most fundamental of all the problems which face a university: What should be the relation between teaching and research? Should one think of a university primarily as a place where learned men learn more? Or should it be a place where learned men, from their reserves of information, instruct the comparatively ill-informed? Dr. W. T. S. Stallybrass, vice-chancellor of the University of Oxford, presided at the discussion.

Prof. G. A. Currie, vice-chancellor of the University of Western Australia, introduced the topic by pointing to the very wide difference between the two concepts of a university held by Bruce Truscott, the creator of "Redbrick", and by Ortega Y. Gasset—two authors who have had considerable influence on those who are concerned with university life. Ortega Y. Gasset holds that the inquiring mind has been disastrous, that the constant, restless wish to discover has led the universities from the cultural centre of the community which is their proper place. Bruce Truscott's view is that "an urgent ferment of the mind" is the essence of a university. Unless the teachers are actively engaged in research, their teaching will be barren and unimportant. The spirit of research is the justification of a university. The two theories are diametrically opposed to each other.

None of the representatives assembled at Oxford was prepared to go all the way with Ortega Y. Gasset—though it was noticeable that two Indian representatives spoke most eloquently of the primary obligation of a university being to teach, and emphasized the harm which has been done by an ill-directed urge to publish the results of research of little value. There was general agreement that the question was, in fact, one of balancing two rival claims, each valid in itself, but each in some danger of strangling the other.

However, to say that there is a need to balance the claims of teaching and research is not to say that every university should strike the same balance. The situation, the development and the size of the university are among many factors which must be borne in mind when deciding how much time each teacher should be able to set aside for research. Similarly, the different faculties will give different answers. There was very general agreement among the scientific speakers at Oxford that it is literally impossible for a teacher of any of the scientific subjects to maintain a high standard unless he is given time for private research. Speakers from other faculties were less emphatic. But it was very clear that the need to safeguard the time of the science teachers, who are at present over-worked and overcrowded, is a very pressing need indeed.

It would be desirable to safeguard the time which a teacher should be able to give to his research by limiting the number of hours during which he or she is required to teach. But the curriculum must be so arranged as to give the teacher not merely the requisite number of hours, but also two or three days in each week when he is able to dedicate himself to research without interruption. It is obviously still more desirable to make it possible for the teacher to carry out research elsewhere if it is more convenient—which can be done only by providing sabbatical years more frequently than any universities can at present afford to do. But sabbatical years are not in themselves the solution of the problem. The teacher needs to be able to do his research concurrently with his teaching.

The problems of safeguarding the teacher's hours of research, the curriculum which makes it possible for him to carry out research, and sabbatical years—all these are administrative problems which the governing body of each university must deal with when it has decided how it proposes to balance the claims of teaching and research. The Congress at Oxford did not make any *ex cathedra* pronouncements on this problem. It was obvious that while the representatives assembled in Oxford were very conscious of the existence of the problem, they were equally clear that it is one which must be settled by each individual in each faculty. There is much research now going on which cannot be said to be of any value either to the research worker himself or to the very few students who will read the printed results. But imaginative research, undertaken, not because promotion depends upon it, but because it is a result of the researcher's enthusiasm for his subject, will make him a better teacher—and will be the more likely to be worth-while research. It is the duty of the academic administrators to make sure that they do not so overload the teacher that this type of research is made impossible.

INTERNATIONAL CONGRESS ON MENTAL HEALTH

THE International Congress on Mental Health held in London during August 11–21, was an event of considerable significance for the social sciences and psychiatry, and the repercussions will be felt far afield. It marked a stage in the struggle of these disciplines, on one hand, for acceptance among the family of sciences, and on the other, for recognition in the world of affairs. The undoubted success of the Congress springs from the marriage of these two aims. It is only possible to give here a passing reference to some of the more important aspects of the Congress, to the immense amount of preparatory work, and to the implications for the future.

The Congress comprised three separate international conferences. The first, on child psychiatry, and the second, on medical psychotherapy, were held during August 11–14; the third and main conference, on mental hygiene, during August 16–21. The Congress was organised by the National Association for

Mental Health, with Dr. J. R. Rees, formerly consulting psychiatrist to the British Army, as president. About two thousand people attended from some fifty countries.

The conferences on child psychiatry and psychotherapy were run on conventional lines. For the first conference the theme chosen was the development of personality in its individual and social aspects, with special emphasis on aggressiveness. Specific topics included aggression in relation to emotional development and in family life, psychiatric problems in education, and the community and the aggressive child.

The subject of guilt formed the theme of the second conference. This was considered under the headings: genesis of guilt, guilt and the dynamics of psychological disorder, and collective guilt. Several of the papers were of exceptional merit, notably those by Dr. John Rickman and Dr. Margaret Mead. The fourth day of this conference was devoted to advances in group therapy. Here the most interesting contribution was perhaps made by Dr. Bion, originator of the 'leaderless group' technique first used in officer selection in the British Army. In the group procedures employed by him, Dr. Bion found it important to elucidate three aspects, first, the group 'mentality' created by the anonymous participation of members; second, the efforts of the members to achieve a full life in the group; and third, the culture of the group.

The International Conference on Mental Hygiene was the third in a series, the first having been held in Washington in 1930, and the second in Paris in 1937. Under the broad heading of "Mental Health and World Citizenship", five topics were considered: problems of world citizenship and good group relations, the individual and society, family problems and psychological disturbance, mental health in industry, and problems of planning. The Conference had the active support of Unesco and the World Health Organisation.

In addition to the plenary sessions, there were more than twenty specialist group meetings, sponsored by such professional bodies or organisations as the Maudsley Hospital, the Institute for the Scientific Treatment of Delinquency, the Royal Society of Medicine, the Tavistock Institute of Human Relations and the British Psychological Society.

The preparations for this conference were on altogether novel lines. Indeed, the conference may be said to have begun eighteen months ago when multi-disciplined professional groups were formed all over the world to collect and evaluate available data, or carry out new inquiries, bearing on the conference topics. During the intervening period about five thousand members of the professions concerned worked in discussion groups in twenty-seven countries. Their deliberations resulted in some three hundred reports dealing with various aspects of the themes chosen for each day of the conference. About one in ten of the members of these discussion groups attended.

These groups were kept in touch with one another by a printed bulletin issued periodically. Ten such bulletins were circulated, and the contents included not only notes on the work of each of these groups, but also a critical discussion of the aims of the conference. The bulletin will continue to circulate for some time after the Congress, so as to provide an early opportunity for publishing material not to be included in the Congress Proceedings.

The three hundred reports, classified according to the five conference topics, were collated and carefully edited, and the edited material passed on to an International Preparatory Commission for further study.

In my opinion, the work of the International Preparatory Commission was the outstanding point of interest in the Congress as a whole. The primary tasks of the Commission were to examine the reports of the national study groups and to prepare a statement to serve as a basis for consideration at the conference. The Commission consisted of twenty members from ten countries and representing disciplines including psychiatry, sociology, psychology, political science, anthropology and social science. The chairman was Mr. Lawrence K. Frank (director of the Caroline Zachry Institute of Human Development). Dr. Otto Klineberg attended as representative of the Unesco project on "tensions affecting international understanding"; and during the last two days, Dr. Brock Chisholm, director-general of the World Health Organisation, was present as observer.

The statement produced by the International Preparatory Commisssion is a document of great significance, not so much because of any original pronouncements it makes, but because it conveys the agreed views of a group of experts from many countries on issues of great moment to-day, particularly those arising out of the problem of war. The statement includes recommendations addressed to national organisations and United Nations agencies in any way concerned with 'mental health'. It is important to make clear that this term 'mental health' was not used by the Commission in any narrow sense, certainly not in the sense of a state of mind which secures immunity from certification under the Lunacy Laws. It denoted rather a state of social well-being, affecting and affected by every important aspect of the life of the individual and community.

Those who took part in the work of the International Preparatory Commission found it a unique and remarkable experience. Ample opportunity was provided to observe tensions in the making, and there were many such tensions to overcome—inter-national, inter-disciplinary and inter-personal. It is safe to say that, in my view, in this particular group the third type of tension was the most difficult to resolve. In the result, an astonishing degree of group cohesion was achieved and a wide measure of agreement on controversial issues cutting across many disciplines. The major psychological effect on the individual members was the extent of 'group involvement' which many of them experienced.

Overshadowing all other topics in the minds of the members of the Commission was the problem of mental health in relation to world citizenship, or more correctly perhaps, as Dr. Edward Glover put it, the problem of "diseases of sovereign groups". Much thought was devoted to detecting points of intervention in the vicious circle of sovereignty and preparation for war; this is discussed in the statement.

Of special interest was the light thrown on the processes involved in an intimately co-operative intellectual effort, on the technique of approach to complex problems, on the correct division of labour between individual and group in a collective activity of this kind, and above all on the curious distorting effect of unconscious factors on reality thinking, even to the extent of blocking the recognition of the most crucial problems of all.

One triumph of the Commission was the final acceptance of the view that what is understood by the term 'mental health' is part of a system of values; it is, in other words, a culturally determined and approved end. It required a tremendous effort to pluck out this view from the mass of anxieties, tensions and resistances which obscured it.

If the Commission made no striking new discoveries, at least it brought to light the fact that multi-disciplined thinking involves more than the mere coming together of diversely educated persons in order to exchange views. Multi-disciplined thinking may operate at many levels. In its most rudimentary form it is simply 'additive', combining the points of view of different disciplines. At a more advanced stage, it requires a new type of concept, which reflects the many-faceted situations of real life. This is one aim of operational research which is essentially a multi-disciplined activity.

The major outcome of the Congress was the formation of a World Federation for Mental Health. This Federation has already been accepted by the World Health Organisation and Unesco as a consultative body on all matters pertaining to mental health in the widest sense. The new organisation will have its roots in the professional groups formed in so many countries to prepare the way for the Congress. These groups will be strongly encouraged to broaden the base of their activities to include all the social sciences as well as psychiatry, and machinery will be devised to link all these groups with the new World Federation. In the way it is hoped to mobilize all the efforts of social scientists, in research and practice, towards the study of the most urgent human problems agitating the contemporary world.

John Cohen

OBITUARIES

Dr. P. R. Lowe, O.B.E.

Percy Roycroft Lowe, who died on August 18, was born at Stamford, Lincolnshire, on January 3, 1870. He was educated privately and went to Jesus College, Cambridge, where he graduated as a B.A., and afterwards qualified in medicine and surgery at Guy's Hospital, London. He served as house physician and surgeon at two hospitals in the Midlands. In 1899 he volunteered for service in South Africa and was appointed medical officer in charge of Princess Christian's hospital train. It was while he was in South Africa that he became interested in ornithology and began to make a collection. On the termination of hostilities he returned to Great Britain and a short time afterwards was appointed private physician to Sir Frederic Johnston. This was a most fortunate appointment for an ornithologist, as Sir Frederic Johnston spent the winters abroad in his private yacht and during the next six years Lowe visited the West Indies and a number of islands in the Atlantic. On these voyages he took every opportunity to study birds and brought together a collection of some three thousand skins which he later presented to the national collection. Lowe contributed a series of papers on his collections, including a study of the genus *Coereba*, in which he paid special attention to the variations in colour in that genus.

In the First World War, Lowe served in Lord Dunraven's yacht fitted up as a hospital ship, and afterwards as a captain in the R.A.M.C. in command of Princess Christian's ambulance train. In 1919 he succeeded Mr. Ogilvie-Grant in charge of the bird collection in the British Museum, and retired in 1935.

Lowe was specially interested in the anatomy and osteology of birds, and was an exceptionally careful and painstaking worker. He made a close study of the Charadriiformes, or wading birds, and published several papers on their classification based on osteological characters and colour pattern. He wrote extensively on the ostriches—both recent and fossil. His studies of the primitive characters of penguins aroused a good deal of criticism, but all will admit that his work on the microscopical structure, arrangement and moult of the feathers of these birds was of outstanding importance. For long there had been much discussion as to whether there were two species of the steamer duck (*Tachyeres*) but it was left to Lowe to prove, in 1934, that there was a volatile and non-volatile species.

Archæologists are indebted to Lowe for proving that the supposed remains of the pheasants from Roman sites in Great Britain are nothing more than the bones of domestic fowls.

It is no exaggeration to say that in the last fifty years Lowe has done more than anyone to advance the study of the anatomy of birds and their classification.

Although Lowe had always been interested in the preservation of birds, it was not until 1925 that he began to take an active part in the cause. In that year he received a letter from the late Prof. Lönnberg directing attention to the grave decline in the numbers of wildfowl in Sweden and asking his advice and assistance. He took up the matter with characteristic energy and started extensive inquiries in Britain and elsewhere. His conclusions, which were published in pamphlet form, went to show that the decline in numbers was mainly due to increased commercialization, and that unless something was done the numbers of wildfowl were bound to go on decreasing. Through his efforts the British Government was persuaded to hold an International Wildfowl Conference in 1927. A year or two earlier the International Committee for Bird Preservation had been founded, and Lowe became secretary of the British Section and for many years was chairman. His efforts in the cause of bird preservation were greatly appreciated on the Continent, and in 1938 he was elected chairman of the European Section. He was president of the British Ornithologists' Union during 1938–43 and in 1946 was awarded the Salvin-Godman Medal for his outstanding work on the anatomy of birds and his efforts in the cause of protection.

In 1924 he married Harriette Dorothy, widow of Charles Parker of Fairlee and younger daughter of the late E. G. B. Meade-Waldo. He is survived by his widow and one daughter.

N. B. Kinnear

Dr. C. A. Elsberg

Charles Elsberg, who died at his home in Stamford, Connecticut, on March 18, was one of the most distinguished neurological surgeons of his generation. When he started his career, neurological surgery did not exist as a specialty. While brain surgery was being developed by Harvey Cushing, the surgery of the spinal cord, in which Elsberg was to win international renown, was in its infancy.

The son of a merchant, Elsberg was born on August 24, 1871, in New York City—the scene of his life's work. Educated at the College of the City of New York, he graduated B.A. in 1890, and three years later took the M.D. at the College of Physicians and Surgeons ('P. and S.') of Columbia University. After serving as interne at the Mount Sinai and Sloane Hospitals, he worked under von Mikulicz-Radecki in Breslau, and on his return was appointed adjunct surgeon at the Mount Sinai. When in 1909 the Neurological Institute opened its doors at 149 East 67th Street, he was offered the post of chief of surgery, which he held until 1937. In 1929 the Institute moved to its present home (168th Street and Fort Washington Avenue) in the Columbia-Presbyterian Medical Center. Its history was told by Elsberg in 1944, in his fascinating and colourful "The Story of a Hospital", which contains a wealth of biographical and autobiographical material. He was editor of the *Bulletin of the Neurological Institute*, begun in 1931, the fifth volume of which was dedicated to him on his sixty-fifth birthday.

In 1917, at the request of the Surgeon-General, Elsberg organised the New York Neurosurgical School for Medical Officers of the American Army, of which he became military director.

His more important writings include "Experimental Investigation of the Treatment of Wounds of the Heart by Means of Suture of the Heart Muscle" (1898), which was translated into many languages, and the classic "Surgical Diseases of the Spinal Cord, Membranes, and Nerve Roots" (1941), which was a revised edition of "Diseases of the Spinal Cord" (1916) and of "Tumors of the Spinal Cord" (1925).

Many honours came Elsberg's way: he was president of the American Neurological Association and of the Society of Neurological Surgeons, and his name is associated with the operation of drainage in syringomyelitis (also known as Pussep's operation). An inspiring teacher—he was very popular as professor of neurological surgery at 'P. and S.' (1921–37) —he was distinguished and youthful in appearance, charming in manner, deeply cultured, and he radiated energy and enthusiasm. W. R. BETT

Mr. J. S. Dow

MR. JOHN STEWART DOW died on August 12. He was born in 1881. After passing through a course in electrical engineering at the City and Guilds of London Engineering College he was for some years on the staff of the College and was later engaged on research work, chiefly on photometric problems.

His early association with Leon Gaster led to the first publication in 1908 of *The Illuminating Engineer*, on which he acted as assistant editor. Since 1928 he had been editor, the name of the journal having been changed to *Light and Lighting* in 1936.

Mr. Dow was even better known for his unbroken connexion with the Illuminating Engineering Society since its foundation in 1909 when he was honorary assistant secretary. In 1928 he became honorary secretary, a position he held until he became president in 1946. After his term of office as president, he continued to serve on the Council of the Society, and during the whole thirty-nine years he was present at every Council meeting. He was a fellow of the Society, and in 1942 was elected an honorary life member, an honour which was shared only by the late Mr. A. P. Trotter.

He was a member of the Departmental Committee on Factory Lighting and of the Illumination Research Committee, as well as of the Lighting Committee of the Building Research Board and numerous other committees concerned with lighting.

He was honorary secretary of the Association of Public Lighting Engineers from 1931 until the end of 1935.

His life's work for the Illuminating Engineering Society cannot be over-valued. He always avoided publicity; but it is due to his work and foresight that the Society has reached its present position. He will be deeply mourned by all associated with lighting matters.

NEWS and VIEWS

New British Association President: Sir John Russell, O.B.E., F.R.S.

AT the British Association meeting just held at Brighton under the presidency of Sir Henry Tizard, Sir John Russell was elected president for the 1949 meeting at Newcastle-upon-Tyne. Sir John has a world-wide reputation as an agricultural scientist. He joined the staff of the Rothamsted Experimental Station in 1907, and succeeded the late Sir Daniel Hall as director in 1912. He retired in 1943, the year of Rothamsted's centenary. During his thirty-one years as director, there was a remarkable expansion of Rothamsted's activities. Various new departments were added, new buildings were erected, and the finest agricultural library in Great Britain, if not in the world, was built up. He also raised the necessary funds for the purchase of the Rothamsted Farm and the Manor House. Sir John has made outstanding contributions to soil science and is the author of several standard works on that subject. He is a former president of the International Society of Soil Science, a foreign associate of the Paris Academy of Sciences, and a member of numerous other academies. Among the distinctions he has received are the Messel Medal of the Society of Chemical Industry and the Albert Medal of the Royal Society of Arts. During the Second World War he was adviser to the Soviet Relations Division of the Ministry of Information and chairman of the Agriculture Sub-Committee of U.N.R.R.A.

Sir John is the first agricultural scientist to become president of the British Association. He has regularly attended the meetings for more than forty years and was the first recorder of agriculture when that subject was a sub-section of botany. Agriculture was made an independent Section in 1912 and Sir John was president of it in 1916 at Newcastle, in 1924 at Toronto and, again, at the centenary meeting in London in 1931. He has served several periods as a member of Council and has been chairman of various committees and a president of the Conference of Delegates of Corresponding Societies. Sir John has travelled widely and has made a special study of agriculture in the U.S.S.R. and Poland. He is about to visit Poland again to take part in the jubilee celebrations of the Academy of Arts and Sciences and will represent the British Association there. He will also give lectures and visit agricultural research institutions on behalf of the British Council.

British Association: Exhibition of Scientific Instruments

ONE of the many interesting features of the Brighton meeting of the British Association was a display of the latest scientific instruments, and particularly of electronic equipment, arranged by the Scientific Instruments Manufacturers Association of Great Britain in the Corn Exchange. The stands were well set out in the ample space available, so that visitors were not subjected to the crowding so often occurring at such exhibitions. In opening the exhibition on September 13, the president of Section A, Sir Lawrence Bragg, paid tribute to the enterprise of instrument manufacturers in organising the display at a time when they were actively engaged in participating in the British Exhibition in Copenhagen. He stressed the importance of accurate, and often very elaborate, instruments both in modern scientific research and in the industrial field. The research worker, he said, has outlived the days of home-made apparatus largely constructed of jam-jars and sealing-wax and has become more and more dependent upon the skill of the instrument maker; and it is necessary for the two to work hand in hand to secure progress. There was a time, and that not long ago, when the scientific world looked mainly to the United States and Germany for the most accurate instrument work, but to-day Great Britain can hold its own in every section of instrument making, and in many it leads the world; in this sphere, at least, Britain no longer fears foreign competition. On the following morning, the whole session of Section A was given up to a symposium on instrumentation and control, including industrial applications of electrical devices, opened by Sir Ewart Smith.

Museum of Archæology and Ethnology, Cambridge: Dr. G. H. S. Bushnell

FOLLOWING the resignation of Dr. T. T. Paterson, Dr. G. H. S. Bushnell has been appointed curator of the Museum of Archæology and Ethnology, Cambridge. Dr. Bushnell is the son of the Rev. D. G. S. Bushnell; he was educated at Wellington and Cambridge, taking his degree in 1925; recently (1947) he obtained the degree of Ph.D. In July 1926 he went to Ecuador as a geologist with Anglo-Ecuadorian Oilfields, Ltd., and remained there with intervals of leave until 1938. It was while working in Ecuador that archæology first attracted his attention, and he examined the southern part of the coastal plain, which up to then had never been studied. He also travelled in Peru, visiting Lima, the Cuzco region, etc., and began to write up the results of his investigations. During the War he held a commission in the Royal Engineers. While an important work is still in the press awaiting publication, there have been numerous articles from Dr. Bushnell's pen on such subjects as an archæological collection from Macas in Ecuador east of the Andes in Oran, and reviews, etc., in various learned journals. Dr. Bushnell is on the Councils of the Society of Antiquaries and the Royal Anthropological Institute. As a keen student of medieval archæology he has also been appointed vice-chairman of the Chelmsford Diocesan Advisory Committee for the Care of Churches. From every point of view Dr. Bushnell should make an ideal curator, for he has considerable personal charm and can arouse enthusiasm in others.

Mathematics in King's College, Newcastle-on-Tyne:

Dr. A. E. Green

ON the retirement of Prof. G. R. Goldsbrough, the chair of applied mathematics at King's College has been filled by the appointment of Dr. A. E. Green. Dr. Green obtained distinction at Cambridge in Part III of the Mathematical Tripos, was a Smith's Prizeman and research fellow of Jesus College. Since 1939 he has held the post of lecturer in mathematics at the Durham Colleges. Dr. Green's published work mainly covers the subjects of hydrodynamics and elasticity. In the former he has dealt with the production of small eddies from large ones, the gliding of a plate on a stream and the fluctuations of pressure in a turbulent fluid. In elasticity he has investigated the stability of thin twisted strips and corrugated plates, and numerous problems in the stress systems of æolotropic plates.

Dr. W. W. Rogosinski

THE chair of pure mathematics at King's College, vacated by Prof. A. C. Offord on his appointment to the chair at Birkbeck College, has been filled by the election of Dr. Werner W. Rogosinski. Dr. Rogosinski studied at the Universities of Breslau, Freiburg and Göttingen. At the last-named he proceeded to the degree of doctor of philosophy in 1921. He held the appointment of *Privatdozent* and later *Ausserordentliche* Professor at the University of Königsberg. In 1937 he came to Great Britain and did some teaching at Cambridge. Later he was appointed assistant in the Mathematics Department of the University of Aberdeen and in 1945 lecturer at King's College, University of Durham, where he was further raised to the status of reader in mathematical analysis in 1947. Dr. Rogosinski has written numerous papers on trigonometric series, Dirichlet's series and problems of complex analysis. He also published "Fouriersche Reihen" (Sammlung Schubert, 1930), and, with the late Prof. G. H. Hardy, the Cambridge Tract on "Fourier Series".

Nicolas Copernicus

IN an article in *The Times* of September 7 on "Poland's Northward Thrust", reference is made to Thorn (now Torun) Allenstein (renamed Olsztyn) and Frauenburg (now Frombork), the three places, in what was formerly East Prussia, in which Copernicus lived and died. To-day the district is a scene of destruction unparalleled elsewhere in Europe. Torun, where Copernicus was born, became Polish after the First World War, and Olsztyn, where he lived for a time, and Frombork, where he worked and died, are now also Polish. In Olsztyn castle, fortunately undamaged, one can see the chamber occupied by Copernicus when he was a canon and administrator of his uncle's diocese; and at Frombork, a small town completely ruined by the War, is the house he lived in and the cathedral in which he was buried. The Polish Government has given a sum of money towards restoring the old quarters of Copernicus in the cathedral close and his tower and observatory. Of the body of Copernicus, however, no trace can be found. "It appears," says the article, "that shortly after the Russians entered Frombork, unknown vandals raided the coffins of bishops and noblemen buried under the cathedral on the basis of a report that many of them wore gold and diamond rings."

Ontario Research Foundation

In his annual report for 1947 to the chairman and governors of Ontario Research Foundation (43 Queens Park, Toronto 5), the Director of Research refers to the virtual completion of the extension of the main building and to a considerable expansion of the scientific and administrative staff. During the year a new Industrial Research Services Department was established particularly to help the numerous small industrial units of the Province, and the Department is expected to handle about two thousand inquiries a year. The Chemistry Department prepared a comprehensive report for the Minister of Mines on the processes in operation for the removal of sulphur gases from smelter fumes; fellowships were concerned with emulsion inks, waxes and transparent paper, sulphite liquor, the manufacture of carboxymethylcellulose, and the polymerization systems butadiene – styrene, butadiene – isoprene and isoprene – styrene. In the Department of Engineering and Metallurgy, sixty-seven investigations were undertaken on behalf of various firms, and fellowships on the influence of chemical composition and physical structure of forged steel balls and their resistance to wear during grinding, and on wire rope, and work on the economics of ferrous smelting in Ontario continued. The Department of Parasitology carried further its work on the life-histories and the factors influencing the activity of black flies and leucocytozoon infection in ruffed grouse and other birds, especially domestic ducklings. Several drugs used successfully in combating malarial infection in man gave negative results on infected birds.

The Physiography Department is completing a study of the geological history of southern Ontario, has co-operated with the Department of Agriculture in a chemical investigation of pasture grasses, and has assisted the Meteorological Service of Canada in equipping and supervising twelve new weather stations at selected points. The work of the Textiles Department has been handicapped by shortage of staff and accommodation; but the Courtaulds (Canada) Ltd. fellowship has continued its work on dye formulæ and methods of finishing and the development of consumer standards, while under the Canadian Industries Ltd. fellowship, in addition to developing fabric construction to meet the demands of the consumer, the behaviour of the nylon fibre under different physical and chemical conditions is being investigated. Some progress is also reported by the Department in investigations on the transmission of water vapour through fabrics, the physical properties of nylon and the factors involved in removing oils used as lubricants after processing textile materials.

Barton's Ruling Engine

In the possession of the Science Museum, London, there are six beautifully engraved buttons, classified as diffraction gratings, which are still regarded as masterpieces. They were the work of Sir John Barton, deputy comptroller of the Royal Mint in the early part of the nineteenth century, about whom little is known personally, but who must have been an ingenious inventor and capable engineer, for in 1806 he invented a differential screw measuring instrument capable of measuring to 10^{-5} inch. In 1822 he was granted a patent for his engraved buttons. After Sir John's death the ruling engine on which the buttons had been ruled passed into the possession of his grandson and then to his great-grandson, Mr. R. V. Barton, who, in 1925, presented the engine, together with some handwritten notes of his father's concerning the working of the machine, to the Science Museum. The above details are given in a valuable and interesting illustrated article entitled "A Ruling Engine Used by Sir John Barton—and its Products" which P. Grodzinski, the technical editor of the *Industrial Diamond Review*, contributes to the February number of that journal. It would appear that this is the first authoritative description.

From his inspection of the machine and relevant documents, Grodzinski concludes that the engine was not Barton's own design but is probably a Harrison straight-line engine. The machine itself is made of brass except for the screws, spindles and pivots, which are steel. The tools are of well-ground steel; but diamond tools, generally octahedral Brazilian stones with curved edges, are provided. Six engraving tools work on six specimens simultaneously, and the method of movement of the tools is ingenious, kinematically sound, and simple. It is fully described in the article, with clear diagrams and photographs. The high precision of division and the engraving of six specimens at once are the special merits of this machine.

Tables of Uranus for the Period 4000 B.C.–A.D. 3000

MM. M. Kamieński and R. Walter have a paper with this title (*Extrait Bull. de l'Acad. Polon. Sci. et Lettres*, 1947) which provides a simple and rapid method for finding the heliocentric co-ordinates of Uranus, the perturbations of the other planets having been taken into consideration in the compilation of the Tables. An explanation of the method for applying the Tables is given, and an accuracy of about 1′ is obtainable, which is sufficient in a great many cases. The Tables should prove very useful, especially in investigating the influence of Uranus on the motions of comets in ancient times, though, of course, they will prove helpful in many other cases as well. Special investigations were made of the long-period inequalities of Uranus, and it seems that these, namely, those of the mean longitude, the eccentric angle, longitude of perihelion, and semi-major axis, can be approximately represented by a Fourier interpolation formula. These inequalities are so regular that the corresponding formula for perturbations in longitude can be extended even beyond the limits of the Table, for the period 6500 B.C.–A.D. 5500, with a mean error of less than 1′.

Conference on Experimental Biology, Peiping

More than one hundred teachers, research workers and senior students in biology of the universities and institutions of Peiping met in the new campus of the College of Agriculture of the National Tsinghua University during July 17–25. The instigator of the conference was Dean P. S. Tang, ably and generously assisted by his colleagues of the College. The campus is next to the famous Summer Palace which was freely accessible to the members during this conference, and one of the most enjoyable parts was the boating at night on the lake inside the Palace. Preliminary meetings consisted of lectures on the place of biology in ancient Chinese history, and on the teaching methods of biology in colleges and high schools. So many contributed valuable suggestions to the latter subject that a special committee was appointed to explore further this important and fertile field. The regular programme consisted of symposia and lectures on recent advances in genetics, hormones, nutrition, viruses and rickettsia, biophysics and aviation physiology. The round-table meetings were attended chiefly by senior members, and the following topics were discussed: cytology, growth and development, immunity, and effect of temperature on organisms. The general impression of the conference was that the time allotted to each speaker was too short, and plans are being made to choose one or two important subjects as the theme of the conference next summer. It was fortunate that the Peiping branch of the Chinese Society of Phytopathology was able to meet with the conference on the afternoons of July 20 and 21.

Hallucinations

The *Proceedings of the Society for Psychical Research* for July (48, Pt. 175) has a suggestive and highly critical article by the research officer, Dr. D. J. West, in which he examines afresh the evidence hitherto collected by the Society for the supernormality of such spontaneous phenomena as precognitive dreams, apparitions and other forms of hallucinations. In the case of the precognitive dream Dr. West concludes that a perfect case has not yet been printed in the Society's publications. "There is always a flaw somewhere," he writes, adding that "the perfect case is a myth" (p. 271). In dealing with the crisis apparition, he points out that numerous and unsuspected sources of error abound, and he indicates his dissatisfaction with the evidence on which those conducting the famous Census of Hallucinations were inclined to rely. Finally, he points out how better evidence could be secured if witnesses could be persuaded to forward their results immediately to some independent source, so that adequate inquiries might be forthwith made and the original documents preserved for subsequent examination and verification.

New Fungi of Madras

A new species of discomycete fungus, *Bulgariastrum tumifaciens*, which causes galls upon living leaves and inflorescences of *Capparidis sepiariæ* is described by T. S. and K. Ramakrishnan (*Proc. Ind. Acad. Sci.*, 27, B, 2; Feb., 1948). This is one of seven new species named by the same authors in their most recent additions to the purely indigenous fungus flora of Madras.

Culture Collections of Micro-organisms

As a result of a recommendation of the Specialist Conference of Culture Collections of Micro-organisms held in London in August 1947 under the auspices of the Standing Committee of the British Commonwealth Scientific Official Conference (1946), national committees were established in the several Dominions and in the United Kingdom for the co-ordination of the activities of existing collections of micro-organisms and to assist in the preparation of collection catalogues. The United Kingdom National Committee will deal also with the Crown Colonies. As a first step in this work, national committees are circulating a questionnaire to all laboratories in their areas at which collections of micro-organisms are known or believed to be maintained. Inevitably some such collections will be missed, particularly those in private hands. Owners of collections of micro-organisms in the United Kingdom and Crown Colonies who have not received a questionnaire are asked to notify Dr. Martin Ware, secretary of the United Kingdom National Committee, at the Medical Research Council, 38 Old Queen Street, Westminster, London, S.W.1.

Installing of Electric Discharge Lamps

Developments in electric discharge lamps and the very rapid increase in their application have produced an urgent requirement for the revision of Section 8 of the Regulations for the Electrical Equipment of Buildings issued by the Institution of Electrical Engineers. A new edition, the twelfth, of the Regulations is at present in preparation; but to meet this immediate need Revised Section 8, "The Installing of Electric Discharge Lamps", has been produced and supersedes, as from July 1, the corresponding section of the eleventh edition. Fluorescent tubes operating at normal mains voltage become, for the first time, a subject of specific requirements under Section 8*A*, which covers all discharge lamp installations in which the open-circuit voltage does not exceed 650 volts. Section 8*B* gives additional requirements for high-voltage installations up to 5,000 volts to earth, which is the maximum voltage permissible.

Colonial Services Appointments

The following appointments in the Colonial Services have been announced: E. S. Porter, agricultural officer, Kenya; H. C. Butcher, chemist, Federation of Malaya; A. R. Giles, land surveyor, Hong Kong; A. L. Griffith, temporary forest officer, Zanzibar; R. A. Neve, specialist, Agricultural Department, Gold Coast; A. G. A. Sutton, Government geologist, Mines Department, Trinidad; R. H. Wharton, medical entomologist, Federation of Malaya; J. G. M. King (agricultural officer, Tanganyika), director of livestock and agricultural services, Basutoland; H. S. Purchase (senior veterinary research officer, Kenya), chief veterinary research officer, Kenya.

Royal Society Scientific Information Conference

A summary of the recommendations of the Scientific Information Conference held during June 21–July 2 has now been issued to delegates; they will be included in the report of the Conference which is now in preparation. The Council of the Royal Society considered these recommendations on July 8, and agreed to receive them. In one of the recommendations the Conference invited the Royal Society to consider setting up a standing committee on scientific information services, and the Council has agreed in principle to do this.

Announcements

A refresher course on "The Mechanical Working of Metals" is being organised by the Institution of Metallurgists and will be held at Ashorne Hill, Leamington Spa, during the week-end beginning October 1. Among those giving lectures are Dr. Hugh Ford, Dr. R. Genders, Dr. E. Orowan, Dr. L. B. Pfeil, Prof. H. W. Swift and Prof. F. C. Thompson.

A Fine Chemical Group of the Society of Chemical Industry, for "the discussion of fine chemicals, especially those of therapeutic or biological interest", has been formed. Meetings are to be held monthly, and the opening address will be delivered by Prof. J. H. Burn, on "Fine Chemicals for Medical Use", at the Royal Institution, London, W.1, on October 5. The chairman of the Group is Sir Jack Drummond, and the honorary secretary is Dr. W. Mitchell, Messrs. Stafford Allen and Sons, Ltd., Wharf Road, London, N.1.

Application of Paper Partition Chromatography to the Separation of the Sugars and their Methylated Derivatives on a Column of Powdered Cellulose

THE analysis of mixtures of sugars resulting from the hydrolysis of a polysaccharide has been greatly facilitated by their separation[1] and quantitative estimation[2] on the paper chromatogram[3]. The application of this technique to the analysis of mixtures of sugars from methylated polysaccharides[4] has simplified a task previously difficult, which involved the fractional distillation of the methyl glycosides and examination of the fractions obtained. The latter method suffers from two disadvantages, in that it requires large quantities of methylated polysaccharides, and that it is very difficult to obtain a complete separation of the methyl glycosides.

The paper chromatographic technique now offers a rapid method of separating and estimating the sugars quantitatively as well as giving a strong indication as to their identities. The final proof of their constitution, however, still depends upon their separation and identification by determination of their physical constants, and the formation of characteristic derivatives. With this in mind we have attempted the separation of the sugars and their methylated derivatives on a column of powdered cellulose, a method similar to that tried by Synge[5], who used a column of potato starch, and similar to that employed by Bell[6], who used a column of silica gel. Using a column of cellulose (Whatman ashless filter tablets, rubbed through an 80-mesh sieve and tightly packed, as a powder, in a tube of 12 in. length and 1½ in. diameter) and with *n*-butanol saturated with water containing 1 per cent of ammonia as the mobile phase, we have separated two- and four-component mixtures of sugars with individual recoveries of 95–100 per cent. The column is purified by washing it with the solvent until the eluate is non-reducing; this ensures that all the soluble impurities have been washed from the cellulose and that equilibrium is reached between the cellulose and the solvent. The maximum weight of any component sugar that can be placed on this column is proportional to its R_G value[4], and is of the order of 200 mgm. for galactose. The syrupy mixture of sugars to be separated is placed on the top of the cellulose and the solvent allowed to percolate down the column. At half-hourly intervals the receiver collecting the eluate is changed automatically. The time taken for any particular sugar to emerge is inversely proportional to its R_G value and is approximately 15 hr. for 2 : 3 : 4 : 6-tetramethyl glucose.

To determine which sugars are present in the receivers, a small spot from each is placed, in order of time, on the starting line of a paper chromatogram, and the sugars separated in the usual manner. On revealing the position of the sugars on the chromatogram by development with ammoniacal silver nitrate, a picture of the distribution of each sugar among the receivers is obtained. From such a chromatogram one may decide which portions of eluate to take in order to obtain a chromatographically pure sample of sugar. While such high recoveries as 95 per cent are quite practical where the components differ widely in R_G values, it is frequently expedient, where one has several components of closely similar R_G values with consequent overlapping of the sugars, to be content to divide the receivers in such a manner as to lead to a lower percentage recovery of a pure fraction. The ease of separation decreases as the R_G values of the particular sugars increase.

By use of the method described above, we have separated in the pure state and in yields of 95 per cent a two-component mixture consisting of *L*-rhamnose (300 mgm.) and *L*-arabinose (200 mgm.) and a four-component mixture consisting of *L*-rhamnose (50 mgm.), *D*-ribose (50 mgm.), *L*-arabinose (50 mgm.) and *D*-galactose (50 mgm.). The isolation of pure crystalline specimens of *L*-rhamnose hydrate and *D*-galactose and of *L*-rhamnose hydrate and *D*-xylose from *Sterculia Setigera* gum and from linseed (Var. Redwing) mucilage respectively has also been achieved.

Methylated sugar beet araban, on hydrolysis, yields in equimolecular amounts 2 : 3 : 5-trimethyl *L*-arabinose, 2 : 3-dimethyl *L*-arabinose and 2-monomethyl *L*-arabinose[7]; pure specimens of each of these sugars have been obtained by use of the above method.

The application of the above technique to the separation and identification of the hydrolysis products of various methylated polysaccharides will be the subject of a later publication.

Oxidation of Ferrous Ions in Aqueous Solution by X- and γ-Radiation

THE oxidation of ferrous ions in dilute sulphuric acid solution by X- and γ-radiation has attracted attention since the work of Fricke[1,2] as a possible method of integral dosimetry for aqueous media[3]. A study has now been made which confirms that the rate of oxidation with dose is essentially independent of the concentration of ferrous ions in the region 10^{-3} to 10^{-4} *M*, and which also shows that this rate is maintained independently of the wave-length of the radiation over a much wider range of wave-length than has hitherto been used in studies of this type.

Four different types of system were employed.

(i) An ionization chamber was constructed of 'Perspex' with graphite electrodes and connected to a D.C. amplifier circuit, and a 'Perspex' irradiation cell was made of identical geometry to the chamber to contain the solution under investigation. The cell and chamber could be interchanged on a stand which was kept in a constant position relative to the tube of an industrial X-ray unit operating at 200 kV. peak and 10 m.amp. The thickness of the cylindrical internal volume of the cell and chamber was only 3·23 mm. In another similar system where this volume was 9·75 mm. in thickness, the yields observed were about 30 per cent lower, due to the absorption of the X-rays in the solution.

(ii) Another ionization chamber and cell combination due to Dr. A. J. Cipriani was used. In this case the ionizing volume was in the form of a thin annulus round a central cylinder containing a 2-curie radium bomb. Cell and chamber were made of polystyrene, and the whole enclosed in a large block of lead.

In both these cases the ionization current in the chamber at saturation passed through a high resistor of known value to ground. The voltage above this resistor was estimated by a null method in both cases, a modified Lauritsen electroscope being used in system (ii). By showing that the ionization current was proportional to the area of the collecting electrodes, and by reversing the polarity of the electrodes, the effect of stray ionization currents was found to be small in both cases.

(iii) A set of stands, 3 in. in height, was placed inside a lead enclosure 18 in. square. On one of the stands was placed a 600 mc. radium capsule, and on another a cylindrical cell containing the solution. By using different combinations of stands the mean distance between source and solution could be varied between 3·7 cm. and 7·6 cm. The radiation intensity at the various positions was measured using a 100-*r*. 'Victoreen' condenser-type chamber with a 5 mm. thick 'Perspex' cap to ensure equilibration of the primary radiation with its secondary electrons.

(iv) A 'Pyrex' cell was constructed with a central thimble in which a glass tube containing a 1,200-mc. capsule of radium could be inserted. The cell could be attached to a vacuum apparatus and evacuated in order to ascertain the effect of removing all dissolved air. No dosimetry was attempted in this system, the purpose here being to compare the oxidation-rate of aerated and evacuated samples, as was done by Fricke[2] and Shishacow[4]. It was found during these experiments that very little oxygen was necessary to saturate the solution effectively with oxygen from the radiation chemical point of view. For example, a solution equilibrated with cylinder nitrogen containing about 2 per cent of oxygen was oxidized within a few per cent of the rate at which an oxygen-equilibrated solution was oxidized. This was true for the small doses used, none of which was higher than 13,000 r.; but at much higher doses one would expect a change of oxidation-rate of solutions initially saturated with air[1,4]. When the solution was evacuated hard for 20–30 min., the oxidation-rate fell sharply to less than one-half of its previous value, as was found by Fricke[1] and Shishacow[4]. The amount of water which evaporated during evacuation was not significant if the solution were made up to its original volume before analysis, as the oxidation-rate has been repeatedly shown to be independent of concentration of ferrous ions within much wider limits[1,2].

The water used in making up the solutions was redistilled successively from alkaline potassium permanganate and alkaline manganous hydroxide, and the solutions were made up with ferrous ammonium sulphate, the ferrous ion concentration varying between 10^{-3} and 10^{-4} *M*, depending on the dose to be administered. All were made 0·8 *N* in sulphuric acid, at which acidity the effect of the ammonium ions was found to be negligible. This acidity was used in order to effect comparison with earlier work. In less acid solutions the reaction is much more complex[5]. The concentration of ferrous ions was followed by potentiometric titration with *N*/5,000 ceric sulphate solution. The rate of change in absence of radiation was negligible during the time occupied by an experiment when the solution was stored in the 'Perspex' cells. Before irradiation, the samples of solution were equilibrated with nitrogen containing a small but constant percentage of oxygen, and the cells were filled in this atmosphere.

The results obtained in these various systems will be presented in detail later. Expressed as the number of atoms of ferrous ion oxidized per 32·5 eV. expended in the solution[6], the ionic yields for solutions containing dissolved oxygen lay between 4·9 and 6·0 in every case, the average value being 5·5. From the ratio of the yields in aerated and evacuated solutions obtained in system (iv) above, the average ionic yield for oxygen-free solutions was found to be 2·2.

Recalculation of the values obtained by Fricke and Shishacow in earlier work[1,2,4], reveals a substantial degree of agreement between the three sets of investigations:

	M/*N* (32·5 eV.) aerated	*M*/*N* (32·5 eV.) air-free
Fricke (refs. 1,2)	5·9	2·3
Shishacow (ref. 4)	5·2	2·0
Present work	5·5	2·2

The above results establish that higher ionic yields than 2·2 observed in solutions of this type which are either not de-aerated at all or are equilibrated with cylinder nitrogen can be ascribed to the presence of dissolved oxygen. The cause of this enhancement is very probably to be associated with the formation of the hydroperoxide radical HO_2 in the reaction $H + O_2 \rightarrow HO_2$, which converts the reducing fragment H formed in the primary act on irradiation of water into an oxidizing agent.

I wish to express my thanks to the National Research Council of Canada and the Ministry of Supply for the use of experimental facilities, and to Dr. A. J. Cipriani, Mr. F. H. Krenz, and Prof. W. V. Mayneord for valuable discussions and assistance in connexion with dosimetry.

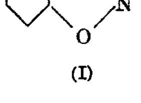
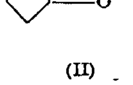
Diazo-Oxides

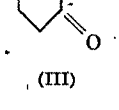
In relation to work recently summarized[1], we have under investigation a number of diazo-oxides. Certain of those theoretically derived from *o*- and *p*-aminophenols (and their derivatives) are included. Satisfactory formulations for these have been debated for



(I)



(II)

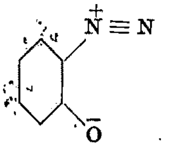


(III)

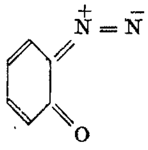
years[2,4]. Earlier writers proposed structures involving rings, such as I[3,4] or II[5], or quinonoid forms, such as III[6]. Hodgson and Marsden[2] conclude, however, that both the *o*- and the *p*- series are best regarded as resonance hybrids of the type

$$\overset{-}{O} - C_6H_4 - \overset{+}{N} \equiv N \longleftrightarrow O = C_6H_4 = \overset{+}{N} = \overset{-}{N}.$$

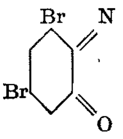
If such a view were correct, it is obvious from IV and V qualitatively that, while the polarity of a *p*-diazo-oxide *could* be small, that of its *o*-isomer should be large, and—in proportion as the ionized form predominates—approach that of a true 'zwitterionic' molecule[7]. Thus the dipole moment of IV is unlikely to be less than *c*. $10D$, while V, on reasonable analogies, might be so low as $4D$.



(IV)



(V)



(VI)

Although we have not been able to prepare the unsubstituted parents IV or V, dipole moment determinations on representative derived members of both the *o*- and the *p*-series are now nearing completion. Results are proving close to those expected for V (that is, also III); for example, μ (found) for VI is $2{\cdot}9D$ (calculated, about $3D$). Ultra-violet spectroscopic evidence is in the same direction.

Very little contribution from fully dipolar forms seems, therefore, to be occurring. We make this preliminary communication because we note that dipolar structures for the *o*-diazo-oxides have been adopted recently by Vaughan and Phillips[8] to explain stability measurements.

Preparation of Nitrogen-free Sulphuric Acid

OF the various methods suggested for the preparation of sulphuric acid suitable for use in nitrate estimations, the method of Atkins[1] is perhaps the most suitable. There is, however, one disadvantage in this method, namely, the precipitation of sulphur if a slight excess of hydrogen sulphide is added. This not only takes a long time to settle, but also interferes with the estimation, often giving lower values due to the presence of traces of sulphur dioxide.

Various alternative methods were tried in this laboratory for the preparation of a suitable sample of sulphuric acid for the estimation of nitrates in sea-water by the reduced strychnine method of Denigès. A good procedure seems to be to treat about 250 ml. of concentrated sulphuric acid (ordinary quality) with 6–10 drops of 40 per cent formalin solution in a 500 ml. Kjeldahl flask, and to boil the mixture until it is decolorized. It is possible to prepare about a litre of good acid in the course of a couple of hours by using a series of flasks. The acid so prepared gives an almost colourless reagent with reduced strychnine.

This method is, therefore, suggested as an alternative where difficulty is experienced in the preparation of acid according to Atkins' method.

Decay and Capture of Slow Mesons in Dielectrics

Conversi, Pancini and Piccioni[1], and others[2], observed decay electrons from positive mesons coming to rest in solids of either light or heavy elements. For negative mesons, however, decay electrons were found in light elements only; for heavy elements it is generally assumed that negative mesons are captured by atomic nuclei before they can decay. The absence of capture of positive mesons can be understood as being due to the influence of Coulomb repulsion[3]; its absence for negative mesons in light nuclei has led Fermi, Teller and Weisskopf[4] to the conclusion that the interaction between nuclei and mesons is much weaker than was assumed hitherto. These authors show that it takes less than 10^{-13} sec. for a meson to reach an energy of about 1,000 eV., where its velocity is about equal to that of electrons in outer orbits, that is, 10^{8} cm./sec. They then consider that the meson quickly loses its remaining energy, reaching the K-orbit of an atomic nucleus in about 10^{-12} sec. It should then be captured by the nucleus in about 10^{-18} sec. if current ideas of interaction between mesons and nuclei are correct. In doing so they have, however, considerably overestimated the energy transfer from slow mesons to electrons[5]. In the present communication reasons are given for believing that in dielectrics the time required by a meson to reach a K-orbit is longer than estimated by Fermi *et al.*, but that it would be very difficult to decide from theoretical considerations whether this time may be of the same order as the decay time ($\sim 2 \times 10^{-6}$ sec.).

Mesons with a velocity less than about 10^{8} cm./sec. (kinetic energy $< 1{,}000$ eV.) transfer energy to electrons (the velocity of which is greater than 10^{8} cm./sec.) at a very low rate (at least in non-metals) because the electrons can follow nearly adiabatically. (This would not hold for free electrons. Even metal electrons are not entirely free, and it seems, indeed, that their deviation from free electrons largely determines inelastic scattering. For, in view of the screening of the meson charge, the collision is of very short duration; development of the effective meson field into a Fourier series will lead mainly to high-frequency terms. The electrons then behave as bound, as for their optical properties.) However, in this region, down to an energy of about $0{\cdot}1$ eV., the rate B of loss of energy to the lattice vibrations is considerable. In ionic crystals, in particular, with residual frequency $\omega_i/2\pi$, it has been shown[6] that:

$$B = C\,\frac{e^2\omega_i^2}{v}\log(v/\omega_i a),$$

where $C \sim 1$, v is velocity of mesons and $a \sim 10^{-8}$ cm. In other types of solids a similar order of magnitude may be expected. Hence the time to slow down a meson from an initial velocity $v_i \sim 10^8$ cm./sec. to a final velocity $v_f \ll v_i$ is

$$\int_{v_f}^{v_i} \frac{\mu v\,dv}{B} \sim \frac{\mu}{10}\,\frac{v_i^3 - v_f^3}{e^2\omega_i^2}$$

(μ is mass of a meson), which is about 10^{-11} sec. if $\omega_i \sim 10^{14}$ sec.$^{-1}$. The above formula holds practically throughout the whole continuous spectrum of the meson. As soon as the discrete spectrum has been reached, with a distance of more than $\hbar\omega_i$ between energy-levels (or rather energy-bands), energy transfer to the lattice vibrations becomes very improbable, because it would involve simultaneous emission of many quanta, $\hbar\omega_i$. In this range either radiative loss or loss due to the Auger effect should be predominant.

The latter was estimated[7] on the assumption that the highest discrete levels should have large quantum numbers and high angular momentum corresponding to nearly circular orbits with radius of about half a lattice distance. Larger orbits would lead to a continuous energy spectrum, whereas penetrating orbits (low angular momentum) would lead to much stronger binding. On the above assumption, emission of an electron (in dielectrics) must be connected with a considerable transfer of angular momentum, which leads to very much smaller transition probabilities than in the ordinary electronic Auger effect. An estimate of the time t_A required for emission of an electron[7] (whereby the reaction on the meson was neglected) gives

$$t_A \sim 10^{-18}\frac{r}{r_e}\left(\frac{v_e}{v}\right)^3 \exp\left(\frac{r}{r_e}\left(\alpha\frac{v_e}{v} + 2\right)\right)\text{ sec.}$$

Here r and r_e are the radii of the mesonic and electronic orbits, v and v_e are the respective velocities and $\alpha \sim 3$. One would expect $v_e/v \sim (\mu/m)^{1/2}$ to be approximately 15.

Although the above formula is based on a simplified model, it serves to show the extreme sensitivity of t_A to the exact value of $rv_e/r_e v$. Thus if, for example, $r = r_e$ and $v_e/v = 6$, then $t_A \sim 10^{-8}$ sec. If, however, $v_e/v = 8$, then $t_A \sim 10^{-4}$ sec.

To estimate the radiative loss it should be possible to treat the meson on a classical basis. Then the rate of loss of energy is approximately $e^2r^2\omega^4/c^3$. Assuming the meson to move in a Coulomb field with effective charge $\bar{Z}e$, it is found that $r^2\omega^4 = e^4\bar{Z}^2/\mu^2r^4$. Hence the time required by the meson to reach an orbit with radius r_f—starting with an initial radius r_i—is approximately

$$\frac{\mu^2c^3}{\bar{Z}e^4}\,(r_i^3 - r_f^3) \sim \frac{\mu^2c^3r_i^3}{\bar{Z}e^4}$$

if $r_f^3 \ll r_i^3$. Assuming $r_i \sim 10^{-8}$ cm. $\sim h^2/me^2$, the time for radiation loss is about

$$t_R \sim \frac{1}{\bar{Z}}\left(\frac{\mu}{m}\right)^2\left(\frac{hc}{e^2}\right)^3\frac{h^3}{me^4} \sim \frac{10^{-6}}{\bar{Z}}\text{ sec.}$$

It thus appears that energy loss due to the Auger effect is extremely sensitive to the properties of the highest bound meson orbit. In contrast to the assumptions made by others[4], it cannot be excluded that in dielectrics it plays only a negligible part compared with radiative loss, which leads to times of the same order as the natural decay time.

Relation between the Masses of Mesons

STARTING from Jeannine Viard's results[1] based on the notion of 'solide principal' in wave-mechanics, and from Eddington's considerations on fundamental frames, we are in agreement with Mme. P. Destouches-Février's principle[2] called the 'principle of respective frames': "All that concerns the actions of observers must be linked to a mean frame; all that concerns the objective properties of particles must be linked to a geometrical frame". It results that the laws of direct action between electrons and photons or between nucleons and mesons, which are actions of contact according to Dirac's δ-function, appear for the observers to obey a Gaussian distribution law with standard deviation σ; the self-energy of one particle in a field is then finite. σ is determined by the assumption that the mass of the electron originates entirely from an electromagnetic energy; thence

$$\sigma = \sqrt{\frac{2}{\pi}}\,\frac{e^2}{m_ec^2} = 5{\cdot}627 \times 10^{-14}\text{ cm.}$$

The self-energy of a nucleon in a mesonic field depends on the mass of mesons. For a given value of this self-energy, there are generally several values of masses. Mme. P. Destouches-Février[3] has proposed a 'principle of associated particles': "Each type of interaction between the particles of a C-kind being expressed by means of particles of spin 1 or 0, is such that one particle of C-kind has a well-determined self-energy $\mathfrak{E}_C$, in the field associated with particles of spin 1 or 0. When, for a given value $\mathfrak{E}_C$, there are several values of masses μ for the particles associated with the field such that $\mathfrak{E}(\mu) = \mathfrak{E}_C$, then the different particles are existing and playing a part in the suitable description of the interaction under consideration; in addition, the existing values of μ are in the neighbourhood of a minimum of the function $\mathfrak{E}(\mu)$".

If we study the function $y(\mu) = \mathfrak{E}(\mu)e^2/g^2$ (where g is the mesonic charge), as M. Cazin[4] has done, we find that $y(\mu)$, for μ increasing from 0, starts from the value m_ec^2 of the self-energy of the electron, and decreases to a minimum at approximately $0{\cdot}365\ m_ec^2$ reached for $\mu \cong 255\ m_e$, then increases to a maximum at about $6\ m_ec^2$ reached for μ slightly less than $800\ m_e$, then decreases to a minimum at about $1{\cdot}8\ m_ec^2$ reached for $\mu \cong 1{,}000\ m_e$.

Admitting the principle of the associated particles, two mesons play a part in the nuclear forces of masses m_μ and m_π, corresponding to the same $\mathfrak{E}_C$-value of the self-energy of a nucleon in the mesonic field; and we have $m_\mu < 255\ m_e$, $m_\pi > 255\ m_e$.

From the $y(\mu)$-function, we can draw the curve giving m_μ as a function of m_π (see accompanying table).

m_μ/m_e	m_π/m_e	m_π/m_μ	$y(\mu)/m_ec^2$
0	407	∞	1
100	364	3·64	0·657
108	360	3·33	0·631
127	350	2·75	0·578
158	331	2·09	0·500
164	329	2·06	0·489
176	320	1·82	0·46
180	318	1·76	0·447
188	313	1·66	0·434
189	312	1·65	0·432
192	310	1·61	0·427
200	305	1·525	0·412
202	304	1·5	0·408
207	300	1·45	0·401
212	297	1·40	0·395
225	284	1·26	0·377
240	270	1·125	0·368
250	260	1·04	0·367
255	255	1	0·365

According to the experimental results reported by Occhialini and Powell[5], Gardner and Lattes[6] obtain $m_\pi = (313 \pm 16)\ m_e$. From the above table, we derive $m_\mu = (188 \pm 24)\, m_e$ and $m_\pi/m_\mu = 1{\cdot}66 \pm 0{\cdot}26$. From the results of Goldschmidt, King, Muirhead and Ritson[7], $m_\pi = (270 \pm 40)\ m_e$; we derive from our table $255\ m_e < m_\pi < 310\ m_e$; $192\ m_e < m_\mu < 255\ m_e$; $1 < m_\pi/m_\mu < 1{\cdot}61$. From the results of Lattes, Occhialini and Powell[8] $m_\pi/m_\mu = 1{\cdot}65 \pm 0{\cdot}15$; we derive from our table $m_\pi = (312 \pm 8)\ m_e$ and $m_\mu = (189 \pm 13)\ m_e$.

These three experimental results agree with the relation between the masses m_μ and m_π given by the principle of the associated particles. The value m_π for the artificial mesons obtained by Gardner and Lattes agrees perfectly with the experimental value of m_π/m_μ for the cosmic mesons obtained by Lattes, Occhialini and Powell; this last determination gives the most accurate results.

So it seems that the nuclear forces may be interpreted as due to mutual exchanges of mesons of the two types. Their spins would be 1 or 0. No arbitrary constant has been introduced and the difficulties of divergence have been removed. Finally, the $y(\mu)$-curve and the principle of the associated particles leads to the possibility of the existence of two particles of spin 1 or 0 and of masses more than 900 m_e; one of these particles may be identified with that found by Leprince-Ringuet; these particles correspond with forces of a type different from ordinary nuclear forces.

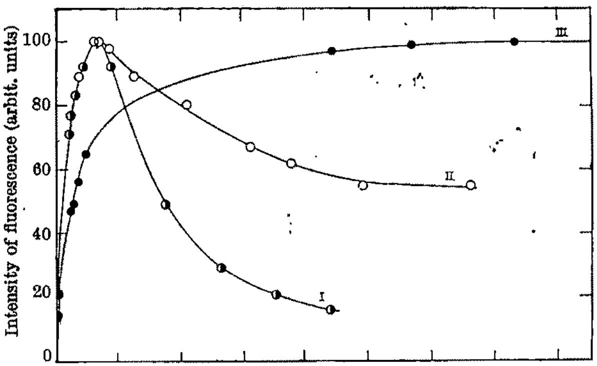
Concentration Quenching of Fluorescence in Chlorophyll Solutions

IN a paper concerned chiefly with the results of measurements of the self-quenching of the fluorescence of solutions of aromatic hydrocarbons[1], Weiss and Weil-Malherbe report a few measurements on the self-quenching of ethyl chlorophyllide solutions. They conclude from these latter results that it is unnecessary to postulate the existence of a long-lived form of excited chlorophyll. This conclusion has been shown by E. Rabinowitch[2] to be inconsistent with the observed[3] high quantum yields for chlorophyll-sensitized photo-oxidation. More recently, the same author[4] has pointed out that the value of the quenching constant obtained by Weiss and Weil-Malherbe is too large to be consistent with the number of encounters between chlorophyll molecules as calculated from kinetic theory.



Curve I: (moles/l.) × 4·75 × 10^4; curves II and III: (moles/l.) × 10^4

A comparison of the quantitative data[5] on the absorption and fluorescence spectra of chlorophyll solutions indicates that the mistake in the work of Weiss and Weil-Malherbe is their disregard of the reabsorption of the fluorescent light. Unfortunately, their report does not contain sufficient experimental detail to permit a computation of the effect of reabsorption upon their results. In particular, they do not specify the nature of the colour filter used in front of their photocell, the wave-lengths present in the incident light, or the ratio of the concentrations of chlorophyllides *a* and *b* present in their sample. For these reasons and because their claims have a direct bearing upon possible mechanisms for photosynthesis, it seemed worth while to repeat their measurements[1] under controlled conditions.

The accompanying graph shows the Weiss and Weil-Malherbe data for ethyl chlorophyllide (curve I) and our data for the fluorescence intensity, obtained by two different methods, of chlorophyll *a* in ether. Since the fluorescence intensities are expressed in arbitrary units, these have been adjusted to make all three maxima identical. For convenience in plotting, the concentration scale for curve I differs from that used for curves II and III.

In the experiments corresponding to these latter curves, the incident light was monochromatic, of λ 4358 A., and the intensity of the fluorescent light was measured with a photocell (Photovolt Corp. Mod. 500). The solutions were made up from freshly prepared chlorophyll *a* and dry ether, and were evacuated to remove oxygen.

The data plotted as curve III were obtained by a method which was designed to eliminate the effect of the reabsorption of the fluorescent light. A colour filter (Wratten Infra-red 88), transmitting only that wave-length region of the fluorescent light which is not detectably absorbed by chlorophyll *a* solutions, was placed in front of the photocell. To minimize further spurious effects of changing concentration, a thin layer (2 mm.) of solution was used, and the photocell faced the side of the cuvette upon which the exciting light was incident. The results obtained under these conditions demonstrate that the self-quenching of the fluorescence of chlorophyll is negligible at all concentrations up to 10^{-3} *M* (a concentration ten-fold greater than the highest value published by Weiss and Weil-Malherbe). Similar results were obtained with chlorophyll *b* and with solutions in acetone and in methanol.

In an attempt to duplicate the results of Weiss and Weil-Malherbe, the Wratten infra-red filter in front of the photocell was replaced with one (Corning 246) which is transparent to the fluorescent light of all wave-lengths but which absorbs λ 4358 A. The photocell was placed "in line with the light source", that is, behind the cuvette. Curve II represents the measurements made in this manner. The measured intensities show the expected effect of reabsorption of the fluorescent radiation by the chlorophyll solution. The reabsorption is not so great in this case as in the measurements of Weiss and Weil-Malherbe, the difference most probably being due chiefly to the different thicknesses of the cuvettes used, and to the fact that solutions of pure chlorophyll *a* (or *b*) were used in our experiments.

We may conclude, therefore, that the effect of self-quenching of the fluorescence (as distinct from possible self-quenching of long-lived excited states) of chlorophyll (and presumably chlorophyllide) solutions is negligible under conditions in which photochemical and optical measurements have been made on these solutions.

The present experiments were made possible by the support of the U.S. Office of Naval Research (Contract Noori-212, T.O. 1).

Polarization of the Raman Line of the Totally Symmetric Vibration of Stannic Chloride

It is well known that the depolarization factors of the Raman lines produced by the totally symmetric vibrations of the XCl_4 molecules of the tetrahedral type are not zero[1]. Recently in this laboratory, it has been shown that the depolarization factors are smaller than the results given by many investigators; but they definitely are not zero[2].

Cabannes and Rousset[3] have pointed out the fact that this residual depolarization could be caused by the isotopes of chlorine, and that a measurement of the depolarization factors of the individual lines due to the various isotopic molecules would decide this point. Welsh, Crawford and Scott[4] have shown that the intensity of the Raman line due to totally symmetric vibration of stannic chloride ($SnCl_4$) is about six times greater than that of the corresponding line of carbon tetrachloride (CCl_4); Langseth[5] has shown that the former gives the same type of isotopic structure as the latter.

Development of the method of polarized incident light[2] for determining depolarization factors, plus availability of a spectrograph suitable for fine-structure investigations[6] along with a newly developed powerful light source having suitable spectral characteristics[7], have made the above-mentioned fine-structure investigation a practical possibility for stannic chloride.

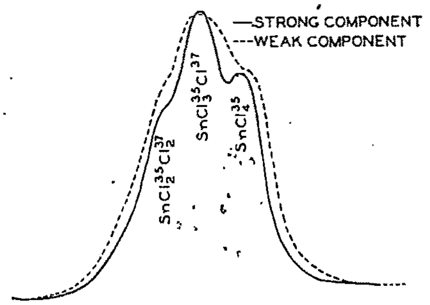
The 'weak' and 'strong' polarized components of the totally symmetric vibration of stannic chloride have been photographed using this high-dispersion spectrograph. The exposure time for the 'weak' component was 48 hr. and for the 'strong' component about 10 min. Microphotometer curves for the two components are reproduced herewith. From inspection of the microphotometer curves it is at once apparent that there is no sensible change in the relative intensities of the isotopic components in the two traces. It is also apparent that the fine structure is almost obliterated in the weak trace due to a broadening of the fine-structure components. The cause of the broadening is definitely not instrumental; since grating ghosts are equally sharp on the 'weak' and the 'strong' plates.

The 'weak' component of the Raman line due to the totally symmetric vibration of carbon tetrachloride is not sufficiently strong to be photographed on the high-dispersion spectrograph. However, if the lack of symmetry of the isotopic molecules is the cause of the residual depolarization, the centre of gravity of the line should be appreciably shifted on a photograph made with the 'strong' and 'weak' components in juxtaposition. This experiment was performed with carbon tetrachloride, using a fast prism spectrograph with excellent defining power (dispersion 30 A./mm.). No noticeable shift of the centre of gravity was observed. The results of these experiments show the following:

(1) The depolarization factors in the three isotopic molecules of stannic chloride are identical within the precision of measurement (better than 0·002). There is reasonable evidence to suggest that the same is true for carbon tetrachloride.

(2) A considerable part of the observed depolarization arises from a small fraction of the total intensity of the line; this small fraction has an intensity distribution different from that of the strong polarized component.

Apart from these experiments, there is evidence to suggest that the isotopes of chlorine cannot cause the finite depolarization factor. When one chlorine atom is replaced by an atom as heavy as bromine or as light as hydrogen, the depolarization factor of the corresponding vibration remains very small. Therefore, judging purely on the basis of the masses involved, the effect of a chlorine isotope should be negligibly small.



Microphotometer traces of the 'strong' and the 'weak' polarized components of the Raman line due to the totally symmetric vibration of $SnCl_4$

One can find at least two possible causes for the small residual depolarization. First, the interaction between the molecules in the liquid may be sufficient to cause both the residual depolarization and the observed broadening of the weak component. Secondly, in the XCl_4 type of molecules, at room temperature a large fraction of the molecules are not in the ground-state but in the degenerate vibrational levels. It is possible that some slight interaction between these modes of vibration may cause the residual depolarization.

This research was carried out on Contract *N60nr-269* Task V of the Office of Naval Research.

Tilted-Plate Compensators

W. A. P. FISHER has recently described[1] a tilted-plate compensator which employed a plate of *CR* 39 resin in place of the usual calcite or quartz. This substitution permitted the development of apparatus of large aperture, although the material is not quite uniform and needs to be rather thick, so that the possible effect of lateral displacement must be considered.

I wish to direct attention to the suitability of lepidolite for the construction of tilted-plate compensators of large field. This material, which is a uniaxial variety of mica, cleaves at right angles to the optic axis and is practically colourless in the thicknesses needed for the production of convenient retardations. The use of such cleavage plates avoids the grinding and polishing required in the case of calcite or quartz and also the difficulties associated with the employment of *CR* 39 resin, including that of the possible variation of calibration with time. The axis about which the lepidolite is tilted lies in the plane containing the leading direction for the magnetic vector.

The following experimental results were obtained with white light using a plate of lepidolite the thickness of which was 0·245 mm. The angle of tilt was observed on a dial graduated in units of 1·8° and the readings have been converted to degrees. Values calculated by means of an approximate theoretical formula are included in the table.

Observed path-difference (λ)	0·5	1·0	1·5	2·0	2·5	3·0	3·5	4·0
Angle of tilt (°)	19·31	27·18	33·93	39·87	45·00	50·04	54·18	58·86
Calculated path-difference (λ)	0·50	0·98	1·50	2·03	2·52	3·04	3·47	3·95

For a plate of thickness t tilted through an angle θ in air, the length of the light path is $t/\cos\varphi$, where $\mu\sin\varphi = \sin\theta$, μ being the refractive index of the material and φ the angle of refraction.

The equivalent path-difference is $(\mu_1-\mu_2)t/\cos\varphi$, μ_1 and μ_2 being the two refractive indices.

$\mu_1^2-\mu_2^2 = K\sin^2\varphi$, K being a constant[2],

$\therefore \mu_1-\mu_2 = (K/2\mu)\sin^2\varphi$. $\mu_1+\mu_2 = 2\mu$, very nearly.

The equivalent path-difference

$$= (K/2\mu)(t\sin^2\varphi)/\cos\varphi$$
$$= (K/2\mu)\,\{(t\sin^2\theta)/\mu^2\}\,\{\mu/(\mu^2-\sin^2\theta)^{1/2}\}$$
$$= (At\sin^2\theta)/(\mu^2-\sin^2\theta)^{1/2},\ A \text{ being } K/2\mu^2.$$

Application of the method of least squares to the experimental results above shows that $At = 6{\cdot}939$ or $A = 28{\cdot}32$, and that $\mu^2 = 2{\cdot}389$. These values were used in calculating the results given in the last line of the table.

Muscovite may also be used in the construction of a tilted-plate compensator of limited range. Tilting about the trace of the plane containing the optic axes causes the retardation to increase until it reaches four times the normal value at an inclination of about 70°. Tilting about a perpendicular axis causes a decrease to zero at an inclination of about 35°.

Thorium and Uranium Content of the Velence Mountains, Hungary

THERE are few areas in Hungary where the occurrence of thorium and uranium minerals is theoretically possible. We investigated during the summer of 1947 the mountains near Lake Velence near the town of Székesfehérvár in Hungary.

Portable battery-operated Geiger–Müller counting equipments have been constructed at this Institute. One of them served in connexion with headphones for a qualitative search only. It was easily portable in a small case and weighed (including built-in batteries suitable for 400 counting hours, high-voltage supply and headphones) less than 5 kgm. The other counter-set possessed an electromagnetic impulse-counter, a more powerful amplifier, and was supplied by a motor-car starter battery (12 volts, 70 ampere-hours) by means of vibrating alternators. The Geiger–Müller counters were of brass, 45 mm. outer diameter, 1·8 mm. wall thickness and 88 mm. length, and were of the self-quenching type, filled with argon and alcohol vapour.

We observed a considerable γ-activity everywhere in the acid eruptive rocks of the area investigated over an area of about 30 km.², which exceeded the intensity of the cosmic radiation (40 impulses per min.) by a factor of 2–3, when the counter was placed immediately on the rocks.

In one case we drove in a boring about 50 cm. deep into the granite wall. We observed an activity of 260 impulses per min., with the counter in the boring. We evaluated this result quantitatively, taking into account the self-absorption of the γ-radiation within the rock, by calibrating the counter with the γ-radiation of thorium in radioactive equilibrium with its decay-bodies. To do this we placed a known amount of thorium (in equilibrium) at a measured distance from the counter and determined the number of impulses per min. The soft components of the γ-radiation were retarded by the thick wall of the counter and by 2 mm. of lead. Calculation shows that the concentration (c) of the radioactive material per gram rock substance, expressed in 'thorium-γ-equivalents', can be calculated from the following expression, approximately :

$$c \approx \frac{\mu J}{A.4\pi.\rho},$$

where μ is the coefficient of the self-absorption per cm. in the rocks, J is the number of impulses counted per min., A is the rate of counting per min. when 1 gm. of thorium is at 1 cm. distance from the counter (as determined above), ρ is the specific density of the rock.

We obtained in this way an approximate value for the concentration in thorium-γ-equivalents, $c = 0{\cdot}12 \times 10^{-3}$ gm. thorium equiv. per gm. rock. About the same order of magnitude of activity was observed everywhere in the acid eruptive rocks (granite, aplite, granitporphyre, etc.). On the other hand, basic eruptive rocks (andesite) and rocks of hydrothermic origin (quartzite) were found to be practically inactive.

Typical samples of the rocks mentioned were removed and tested carefully in the laboratory of the Institute. We checked at first the share of potassium in the γ-counting-rate. The potassium content of the rocks amounted to 3–4 per cent K_2O [1]. We mixed potassium nitrate to an inactive quartz powder in amount equivalent to 4 per cent K_2O content and found that the observed activity remained at about the level of statistical errors, and could be made responsible for no more than 10–15 per cent of the activity of the investigated eruptive rocks.

For the determination of the origin of the activity, Dr. M. Vogl-Földvári brought samples of the rocks into complete solution, and we determined the equilibrium radon content of the solutions by means of a calibrated emanometer. The equilibrium thoron content was determined under steady gas circulation, because of its short half-life. The calibration of the emanometer for thoron was carried out exactly in the same way, with the same velocity of gas circulation, using a small known dissolved amount of very old thorium nitrate. The accompanying table shows the results.

Rock sample, place	gm. U/gm. rock	gm. Th/gm. rock
Granite from Velence	$0{\cdot}87 \times 10^{-5}$	$4{\cdot}2 \times 10^{-5}$
Granite from Nadap (rich in biotite)	$0{\cdot}86 \times 10^{-5}$	$4{\cdot}0 \times 10^{-5}$
Aplite from Nadap	$0{\cdot}80 \times 10^{-5}$	$5{\cdot}6 \times 10^{-5}$

The acid eruptive rocks of the Velence Mountains everywhere contain similar concentrations of thorium and uranium, namely, about 8–9 gm. uranium per thousand kgm. rock and 40–60 gm. thorium per thousand kgm. rock. It seems doubtful whether so small a concentration will be of any use, unless very cheap concentrating processes should be found. It is of importance, however, that this thorium and uranium content makes possible the exact determination of the age of the rocks.

No concentrated deposits or ores were found during this preliminary survey.

A detailed publication (also in English) will appear in the *Transactions of the Hungarian National Geological Institution*, Budapest. I am indebted to the Hungarian National Geological Institution and to the Hungarian Ministry of Industry and Mining for supporting this investigation, and to Dr. A. Földvári, chief geologist of the Institution, for geological advice during this survey.

Maxwell's 'Fish Eye' as an Ideal Electron Lens

THE most famous optical medium furnishing a perfect optical image formation is the well-known 'fish eye' of Maxwell[1], the refractive index of which $n(r)$ is given by the spherical distribution

$$n(r) = A/(a^2 + r^2), \qquad (1)$$

where A and a are constants. The trajectories are circles. Other media with ideal image formation have been found by W. Lenz[2], and they are of the form

$$n(r) = A/r\left[\left(\frac{r}{a}\right)^p + \left(\frac{q}{r}\right)^p\right] \quad (p = 1, 3, 5, \ldots). \qquad (2)$$

The most obvious way of analogous construction of an ideal electron lens would be the realization of the corresponding potential

$$V(r) = \frac{A^2}{(q^2 + r^2)^2}, \text{ or } V(r) = \frac{A^2}{r^2\left[\left(\frac{q}{r}\right)^p + \left(\frac{q}{r}\right)^p\right]^2},$$
$$(p = 1, 3, 5, \ldots), \qquad (3 \text{ and } 4)$$

by a spherical or axial symmetrical distribution of space charge[3]. This method is technically impossible, however, in the present state of development.

But limiting ourselves to plane image formation, an ideal electron lens could be constructed by a set of axially symmetrical metallic electrodes without space charge, which in a plane $z = z_0$ perpendicular to the axis must produce the potential distribution (3) or (4). We shall show in the following that such an electron lens can be constructed.

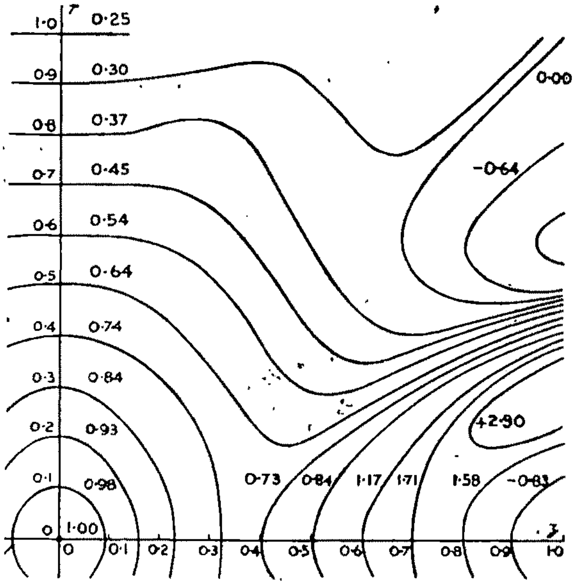
The general solution of the differential equation for an axially symmetrical potential is

$$\varphi(r,z) = \int_0^\infty C(k) J_0(ikr)\,(c_1 e^{ikz} + c_2 e^{-ikz})\,dk. \qquad (5)$$

The function $C(k)$ can be determined by means of Hankel's integral theorem[4] in such a way that for $z = z_0$ (for example, $z_0 = 0$) the potential will be $V(r) = A/(a^2 + r^2)$. We get

$$\varphi(r,z) = -\frac{iA^2}{2a}\int_0^\infty J_0(irk)\,K_1(iak)\cos kz\,.\,k^2dk, \qquad (6)$$

where $J(irk)$ is the Bessel function of the order zero, and $K_1(iak)$ the so-called Macdonald function of the



first order (see, for example, G. N. Watson, l.c, p. 78). Since one finds,

$$\int_0^\infty J_0\,(ikr)\,K_1\,(ika)\,k^2dk \;=\; \frac{2ia}{(q^2+r^2)^2}, \qquad (7)$$

it can be easily shown that (6) is indeed that solution of $\Delta\varphi = 0$, which has for $z = 0$ the form (3). The shape of the electrodes might be calculated from $\varphi(r,z) = \text{const.}$

But more important than these formulæ of the potentials required is development in series, by means of which we are able to calculate them numerically. One finds for the general form of the potential having the required distribution in the plane $z = 0$ the expression

$$\varphi(0,r) \;=\; V(r) \qquad (8)$$

$$\varphi(r,z) = \sum_{\nu=0}^{\infty}\,(-1)^\nu\,\frac{(\nu\,!)^2\,2^{2\nu}}{(2\nu)\,!}\,z^{2\nu}\,\sum_{\mu=0}^{\nu}\,\frac{V^{(\nu+\mu)}_{(r^2)}}{(\mu\,!)^2\,(\nu-\mu)}r^{2\mu}, \qquad (9)$$

and this becomes in our case (3)

$$\varphi(r,z) = \frac{1}{(1+r^2)^2}\,\sum_{\nu=0}^{\infty}\,(-1)^\nu\,b_{2\nu}\left(\frac{2z}{(1+r_2)}\right)^{2\nu}, \qquad (10)$$

in which the $b_{2\nu}$ are the following polynomials

$$b_{2\nu} \;=\; \frac{(\nu\,!)^2\,(\nu+1)}{(2\nu)\,!}\,\sum_{k=0}^{\nu}{}'\,(-1)^k\binom{\nu}{k}\binom{\nu+1}{k}r^{2k}. \qquad (11)$$

Since for (9), $\left(\frac{\partial\varphi}{\partial z}\right)_{z=0} = 0$, the force on the electron perpendicular to the plane $z=0$ vanishes, that is, the electron having the initial velocity in the plane $z=0$ stays in this plane. My collaborator, H. Robl, has worked out these formulæ, and the surfaces $\varphi(r,z) = \text{const.}$ are represented in the accompanying graph. It is imagined to be rotated about the z-axis. It is only necessary to imitate two of the equipotential surfaces at the top and below and on the sides by metallic electrodes in order to have the required potential distribution in the plane $z = 0$, where all (circular) trajectories from a point are exactly focused to an image point. It is possible to show by means of Larmor's theorem that a uniform magnetic field can also be combined with the electric field. Such a perfect cylindrical lens might be especially useful for a velocity-spectrometer, since only particles of the same velocity are focused to the same point; and perhaps (combined with a magnetic field) it might also be applied in mass-spectrography. In order to improve the stability of the electron trajectories in the plane $z = 0$ it will be necessary to investigate also the other potentials of the type (4) found by Lenz, for a suitable exponent p.

A discussion of this subject will be given shortly in the *Acta Physica Austriaca.*

[3] Gabor, D., *Nature*, 150, 650 (1942); *Electronic Eng.*, 15, 295, 328 and 372 (1942–43). See also Cosslett, V. E., "Introduction to Electron Optics", 142 (Oxford, 1946). Gabor maintains in the above-mentioned papers that the ideal electron lens of Maxwell type (3) is unique in the three-dimensional case; this is in contradiction with the result (4) of Lenz. For the two-dimensional case, however, Gabor states that the solution (3) is not unique.

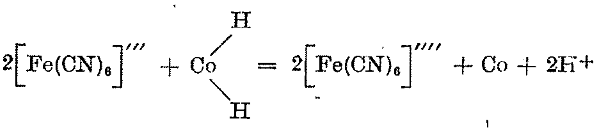
Source of the Hydrogen Ions in Gastric Juice

A FLOW of water from the oxyntic cells through a membrane permeable to chlorine ions and limited in its cation permeability to hydrogen ions should result in a secretion of hydrochloric acid in accordance with the view of Hollander[1]. It can be shown, however, that under such conditions the concentration of hydrogen and chlorine ions in the secretion would be of the order of 10^{-3}–$10^{-4}\,N$, and unless we add further hypotheses, including relatively very large water reabsorption, it would seem necessary to suppose a primary concentrating of hydrogen ions within the cell. It would appear that the simplest manner in which this could be achieved is by way of an organic acid produced metabolically or in relation to metabolic activities, hydrolysis of esters and the like. From the data of Davies *et al.*[4] showing that under their conditions Q_{HCl} can be greater than Q_{O_2}, the view was entertained that the organic acid might be cyclically reformed or restored[3].

From our studies with yeast[5] and the high acidic formation resulting from exchanges of potassium and hydrogen ions, a further stepping up of the hydrogen ion concentration could occur by exchange of hydrogen ion for an inorganic cation.

It may be pointed out that one of the catalysts involved in the passage of metabolic hydrogen to oxygen could conceivably function as such an acid, and the purpose of the present communication is merely to indicate such a possibility, which further exemplifies our previous hypothesis in which phosphoglyceric acid was used as an illustration.

It may be noted that in the metabolism of 1 molecule of glucose, 24 hydrogen atoms pass to oxygen, 12 from the original carbohydrate molecule and 12 from water incorporated at various stages. The metabolic hydrogens can be regarded as converted at some stage into electrons and free hydrogen ions. This does not happen at the stage of the pyridine nucleotides, but appears to happen at or before the stage of the cytochromes. It is of interest to note that Quastel[6] has used the reaction:



$$2\left[\text{Fe(CN)}_6\right]''' + \text{Co}\begin{matrix}\diagup \text{H}\\ \diagdown \text{H}\end{matrix} = 2\left[\text{Fe(CN)}_6\right]'''' + \text{Co} + 2\text{H}^+$$

to determine the concentration of cozymase, by measuring the acidity produced, through its effect on bicarbonate.

If all the metabolic hydrogens were utilized to supply the hydrogen ions of the gastric juice, the upper limit of the ratio $Q_{\text{HCl}}/Q_{\text{O}_2}$, from this source alone, would be 4.

When the electrons pass to oxygen, hydrogen ions are in turn withdrawn from the cell. Ordinarily the addition and withdrawal quantitatively balance without alteration of pH from such exchanges; but it may be possible that the stage of hydrogen ion formation can be effectively separated in the oxyntic cell from the stage of withdrawal. Such might occur, for example, if the donation of hydrogen atoms and conversion to hydrogen ions and electrons took place at a surface with fixed enzyme units of the donator and free diffusion back, through the cell, of the electron carriers.

Such amplifications of our earlier view had been entertained here prior to the appearance of a communication to the Biochemical Society (April 1948) of Davies and co-workers, in which they refer to a hypothesis of Crane, Davies and Longmuir (to be published), and which "requires that H atom transport by dehydrogenating enzymes is part of the mechanism by which H ions are secreted".

Upon inquiry, it would appear that this hypothesis does not include the supposition that the metabolic hydrogen atoms supply directly the hydrogen ions of the gastric juice in the manner indicated above, and which is an extension of a possible mechanism we had previously put forward[3]. Such would largely simulate the production by the yeast cell of a pH as low as 1·5 in the suspending fluid, and due to free hydrochloric acid.

An Antigen Related to the *ABO* System

WE have studied a serum containing an agglutinin, provisionally named 'anti-Ken' after the patient's name. This agglutinin was formed by a Polish patient, aged twenty-four, in response to pregnancies: the first ended in a stillborn macerated fœtus at term, the second was successfully interrupted by Cæsarean section during the thirty-seventh week. The patient was group A_2 *M CDe CDe Ken-* and her husband *B MN cDE cDE* (or *cDE cde*); we could not distinguish between these genotypes owing to the lack of anti-*d* and anti-*e* sera. The baby proved to be group *O MN CDe cDE Ken+*.

During the second pregnancy, as there were many possibilities of immunization, abnormal anti-*B*, *N*,*c*(*Hr'*), *d*(*Hr*) or *E*(*Rh''*) antibodies were searched thoroughly. The characters of the anti-*B* agglutinin remained normal: titre, 1 : 512, thermal optimum at 4° C., no exaltation by human serum or 30 per cent bovine albumin. At the thirty-second week an agglutinin was found active at 37° C. on certain *O* and *A* cells. It did not correspond to one of the *Rh* antigens mentioned above, nor to the *N* antigen.

Ten days after delivery a suitable amount of serum was obtained. It reacted strongly with the baby's cells and certain *A* and *O* bloods, giving a visual agglutination up to 1 : 4 and a final titre of 1 : 32 (in saline) at 37° C. Its activity was markedly increased when 30 per cent bovine albumin was used as diluent.

Testing with *A* and *O* cells of known *D* (*Rh*) type gave the following results:

Reaction with anti-*Ken*		+	—
248 unselected *A* and *O* bloods	*A* cells	46	45
	O cells	102	55
	D+ cells	132	83
	D− cells	16	17

There is at first sight an evident discrepancy in the distribution of *Ken*+ and *Ken*− cells among *A* and *O* groups, and, in a minor way, among *D*+ and *D*− cells. The latter does not appear to be significant whereas the former indicates a true difference between the *A* and *O* cell-groups. The χ^2 and p values are given in the following table. Owing to the small number of samples, the Yates adjustment was applied.

	χ^2	p
A–O distribution	4·396	0·036
D+ *D*− distribution	1·4814	0·224

The observed difference would appear by chance in only 1 in 30 trials for the *A–O* distribution and about 1 in 5 for the *D* distribution. Therefore the *Ken* antigen is found with a significantly higher frequency in the *O* group and is probably related to the *ABO* system. Its genetical transmission is being studied and will be described later.

We are indebted to Pr. Olbrechts and Mrs. Olbrechts-Tyteca for advice in the statistical work, to Drs. R. R. Race and A. E. Mourant for the sera used in genotype determinations, and to J. Snoeck for permission to publish the case.

Error in Counting Reticulocytes

WHEN immature mammalian red cells, or reticulocytes, are stained with brilliant Cresyl Blue they may be differentiated from adult red cells and enumerated in a sample as a percentage. If these cells were scattered according to chance, reticulocyte counts would be expected to follow the binomial distribution. In a recent paper, however, Jacobsen, Plum and Rasch[1] have shown that, in their laboratory, reticulocytes appear to be more regularly arranged than this when present in a proportion greater than 10 per cent. They are therefore able to make counts on one sample with remarkably close agreement. Much of the important work on reticulocyte maturation carried out in their laboratory depends on the great accuracy with which this technique is used. It was therefore thought that an independent attempt to confirm this deviation from the binomial distribution would be of interest.

Replicate counts were made on a human case of pernicious anæmia with 13 per cent and on an anæmic rabbit with 20 per cent of reticulocytes. In all, 66,000 red cells were counted. In the human case the counts corresponded fairly well with the binomial distribution; but in the rabbit the counts were less regular.

These results differ markedly from those of Jacobsen, Plum and Rasch, who record increasing accuracy with the higher counts. The discrepancy may have been due to inferior skill both in making the preparations and in counting, for clearly a laboratory worker whose whole time is occupied in counting reticulocytes will attain an unusual ability. On the other hand, this technique gives great scope for unconscious bias. Reticulocytes cannot be distinguished from adult red cells as black from white. The maturation of a red cell is a gradual process, and reticulocytes merge imperceptibly into mature red cells. The difficulty is demonstrated in the photographs from which some of the counts made by Jacobsen, Plum and Rasch were taken. In the two examples published in their paper are six cells which we would consider mature reticulocytes, but only one of these is so classed by them.

In the simple enumeration of red cells, it is the highly skilled worker who can obtain closer agreement between replicate counts than the Poisson distribution will allow. Similarly, in counting reticulocytes, the highly skilled technician might be liable to bias in favour of excessive accuracy. Despite the care taken to avoid bias, it is therefore possible that the extreme accuracy of these authors may be due to the unconscious adjustment of counts by the inclusion or exclusion of the more mature reticulocytes. This possible source of bias could be eliminated if counts were made by a number of competent and independent hæmatologists from unmarked and unselected photographs made by Jacobsen, Plum and Rasch.

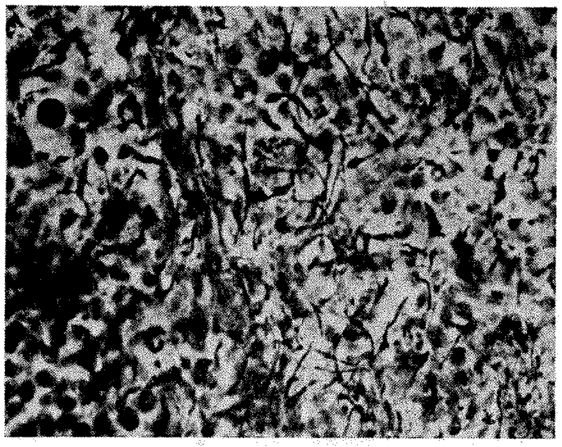
Innervation of the Adenohypophysis

THERE is strong evidence that the nervous system controls the pituitary gland and its secretions; but the exact nature of the control is undecided. General agreement exists about the importance of the nerve connexions for the normal functioning of the pars nervosa of the posterior lobe. The influence of the nerve supply on the adenohypophysis is, however, still under discussion and has been denied altogether. Experimental sections of the hypophyseal stalk and related hypothalamic structures have produced conflicting results; but no alternative way of nerve supply has been established, and the stalk is still considered the most probable link between the pituitary body and the central nervous system.

The morphological descriptions of the gland provide many references to the presence of nerve fibres in the glandular hypophysis; but few complete and detailed descriptions of the origin and endings of such fibres. Perhaps for this reason the evidence in favour of the abundant nerve supply of the gland has been usually under-estimated.



In a study of the rabbit's pituitary gland, using Cajal's method on frozen sections, I have been able to show the rich innervation of the glandular parts (intermedia, tuberalis and distalis). The nerve fibres come from the hypothalamic-hypophyseal tract. They appear mostly as isolated elements, passing directly from the stalk and from the pars nervosa (infundibular process) to the pars tuberalis and intermedia. They are particularly abundant at the junction of the pars tuberalis and pars distalis, a region named the 'zona tuberalis', which Harris[1] has recently studied. Individually or in small bundles, these fibres follow the general direction of the portal vessels and thus reach the pars distalis. Other fibres reach the pars distalis after crossing the pars intermedia, especially at its caudal end, where they are very numerous. In some cases the fibres leaving the hypothalamic-hypophyseal tract form a thick bundle which, before entering the zona tuberalis, runs along the stalk for a short distance quite separate from the main tract directed to the pars nervosa. This is particularly clear in new-born and very young animals.

The nerve fibres of the adenohypophysis seem to have an almost uniform type of ending as small clubs or knob-like formations applied to the cells. From the relative numbers of endings and cellular nuclei visible, there seems to be only one of these formations for each cell. Even when the fibres remain unstained, it is often possible to see clearly the nerve endings as black knobs or disks in almost equal numbers to the nuclei.

The accompanying reproduction shows some fibres in the pars distalis of the adult rabbit, and the small club-like endings are also visible in parts of the field. This type of nerve-ending was described and illustrated by Croll[2] also in the adenohypophysis of the rabbit, and by several authors in other species.

A full description of this work will be published elsewhere.

Occurrence of Thin Membranes in the Structure of Wool

WOOL keratin is considered to be completely soluble in sodium sulphide. 30 ml. of 0·3 *M* sodium sulphide was added to 1 gm. carefully purified wool, and this mixture was allowed to stand for about a month. After this time a light green solution was obtained, but the solution showed a slight opalescence. The particles causing this opalescence (estimated to be not more than 0·1 per cent of the wool) could be separated from the solution by centrifuging. After separating and washing with water, the solid matter was examined under the electron microscope. The specimen was mounted on collodion and observed directly. The solids proved to consist mainly of thin membranes, mostly rolled or folded, as is seen in Fig. 1. In order to determine the thickness of the membrane itself a collodion replica was made and gold-shadowed at a declination of 1 : 10. Fig. 2 shows how the thin membranes are rolled and the rolls flattened, probably by the surface tension during the drying. From the length of the shadows the thickness is calculated to be something between 50 and 100 A. Fig. 3 is a shadow-cast replica, where part of the wool membrane has stuck to the collodion. In part it shows both the membrane and the corresponding impression and is in that way interesting purely from the electron-micrograph point of view.

As these thin membranes are resistant to sodium sulphide, we think it justified to assume them to have a chemical composition different from the ordinary wool keratin.

It would be of great interest, of course, to know where the membranes are located in the wool fibre. It is also essential to know the chemical structure of the membranes and their behaviour towards chemical agents and enzymes. A chemical analysis is being carried out.

A sample of wool was strongly chlorinated and the excess chlorine afterwards removed by a solution of sodium bisulphite. The sample was then repeatedly treated by supersonics and the water dispersion from each treatment was examined under the electron-microscope. In the first suspension there were numerous fragments from membranes similar to those mentioned above. In the second and following suspensions the occurrence of the membranes was more and more rare, but the wool still had the fibre character and even partly a scale structure. This can be taken as an indication that the membranes are located in the surface layer of the wool. Further investigations are necessary before more definite conclusions can be drawn.

If it be a fact that these membranes are located at the surface or in the outer layers of the wool and do not dissolve in an alkaline and reducing agent like sodium sulphide, it may have an important bearing on surface phenomena such as the frictional properties of the fibres and the diffusion of dyes into the fibres.

Action of Streptomycin on Plant Tumours

In previous reports on the effect of streptomycin on plant tumours produced by *Phytomonas tumefaciens*, it was stated that this antibiotic substance would 'cure' a variety of plants of crown-gall[1], and that it killed tumour tissue in these galls without influencing normal cells[2]. To obtain more information about the action of this agent, experiments were performed using *in vitro* methods which made possible more exact control of dosage and closer observation of effects.

Cylinders of sterile carrot tissue 10 mm. diameter × 6 mm. high were placed on sucrose mineral agar. The upper surface of these fragments was covered with a suspension of fully virulent crown-gall organisms. About 15×10^8 viable organisms were applied to each fragment in this way. After 1, 2, 6 and 8 days, the fragments were transferred to sucrose mineral agar containing $50\,\gamma$ per ml. streptomycin, and their upper surfaces were covered with 0·06 ml. of a solution containing $500\,\gamma$ per ml. streptomycin. One group was left on streptomycin-free agar as a control.

After three weeks incubation in light at 25° C., the distribution of tumours in the variously treated groups was found to be as shown in the table :

Frequency of tumour formation in fragments of carrot tissue treated with streptomycin

Interval between inoculation and streptomycin treatment	Number of fragments showing tumours (out of 10)
1 day	1
2 days	3
6 days	10
8 days	10
Untreated control	10

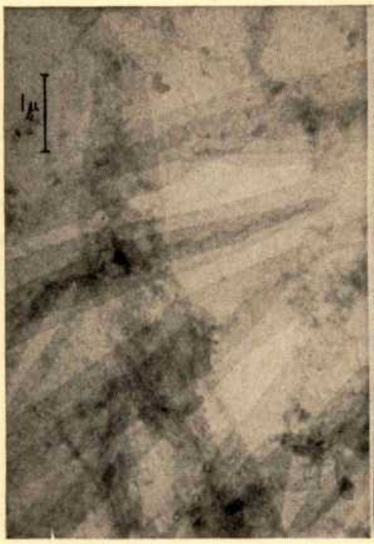

Fig. 1

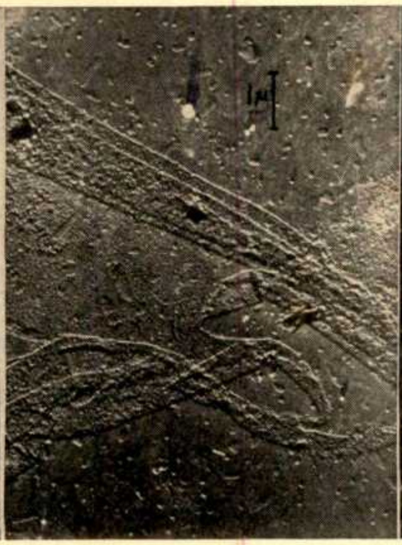

Fig. 2

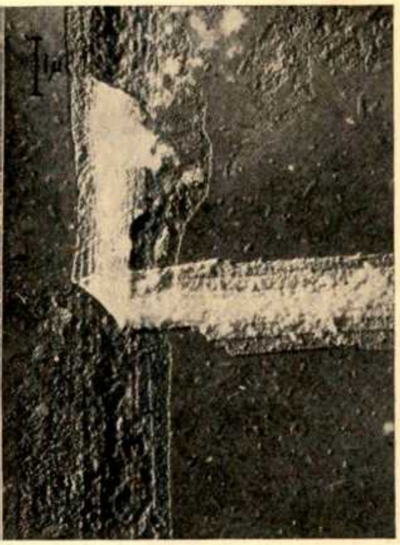

Fig. 3

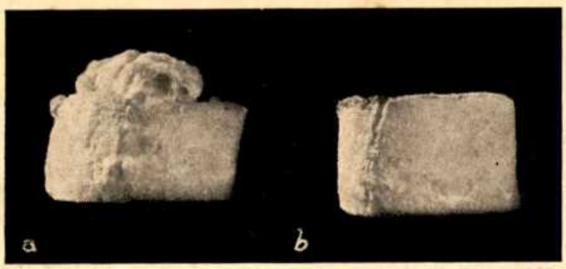
Fig. 1. Electron micrograph of membranes from wool. Fig. 2. Collodion replica of the membranes on glass ; gold-shadowed. Fig. 3. Collodion replica as Fig. 2 ; part of the membrane has stuck to the collodion



(*a*) Cylinder of carrot tissue treated with crown-gall bacteria and cultured for 3 weeks *in vitro*. A large green tumour has formed on the upper surface. (*b*) Cylinder of tissue treated as (*a*) but with 0·03 ml. of a solution of 500 γ per ml. streptomycin applied to the upper surface one day after inoculation. No trace of tumour formation was visible on this fragment

Where streptomycin was applied one or two days after inoculation, almost complete inhibition of tumour formation occurred. The tumours which did develop were very small. At six days, tumefaction had already started. Application of streptomycin at this time slightly reduced the growth of the tumours and changed their appearance, untreated tumours being green, treated ones white. The accompanying reproduction shows the difference in appearance between a fragment of carrot tissue on which the tumour developed and one on which it was inhibited by streptomycin.

When bacteria-free sunflower tumour tissue was cultured on sucrose agar containing 50 γ per ml. streptomycin, growth was only 65 per cent of that made by tissue on streptomycin-free agar. It was also found that 50 γ per ml. of streptomycin would completely inhibit the growth of roots on sunflower stem fragments treated with indole acetic acid, though it did not inhibit their initiation. It seems more probable that streptomycin is a general inhibitor of the growth of embryonic plant tissue than a specific inhibitor of tumour tissue. Its inhibiting effect on tumour formation is probably due to its action on the bacterial inciting agent.

This work was done in part on an American Cancer Society grant recommended by the National Research Council Committee on Growth.

Antigenic Components of *Psittacosis* Virus

THERE is much evidence that viruses of the *Psittacosis-Lymphogranuloma* group are antigenically related. Some of the most active reagents for use in diagnosis by the complement-fixation reaction are virus suspensions which have been boiled[1]. It has also been found that treatment of egg-grown *Lymphogranuloma* by phenol and boiling, by urea or by extraction with ether yield products of enhanced activity which, however, will react with antibodies evoked by the heterologous as well as the homologous species[2,3]. Many observations, recently reviewed by Cox[4], indicate the frequency of serological cross-reactions between various members of this group, and the production of specifically reacting antigens is clearly of importance.

Complement-fixation studies with hyper-immune guinea pig sera absorbed with unheated or boiled *Psittacosis* suspensions have led to the conclusion that this virus possesses at least two antigens, one destroyed by heat, the other resistant[5]. Evidence, not yet published, that specificity is a property of the labile antigen has also been obtained[6].

In other instances the serological activity of a specific antigen has been demonstrated, and the toxin neutralization experiments of Rake and Jones[7] suggest that this may be identified with the specific toxic factor which they describe. Mammalian sera may often be relatively deficient in specific antibody and there is evidence from infection neutralization[8] and complement-fixation tests[9] that avian sera are more potent in this respect. Virus agglutination methods may also be of value in detecting specific reactions[10].

In the course of an investigation into the antigenic properties of *Psittacosis* and related viruses, two types of antisera were prepared in the guinea pig: one designated 'complete' by the injection of *Psittacosis* in the fresh state, the other designated 'group' against the virus heated in a boiling water-bath. These suspensions were made from yolk-sac material, and the sera were tested by complement fixation against similar antigens from mouse spleen.

It was found that unheated antigens, rich in virus, gave variable results in that they might fail altogether to fix complement in the presence of either antiserum, but more often preparations of this sort gave good fixation with the 'complete' serum and very much less or no fixation with comparable dilutions of the 'group' serum. Regardless of its initial behaviour in the fresh state, heating the suspension consistently altered it, so that it reacted fully with both types of serum. The same effect was produced by treatment with papain or with dilute mineral acid.

As was expected, after absorption with the heated virus, the 'complete' serum retained reactivity only with the unheated preparation: similar treatment of the 'group' serum removed its fixing powers with the heated antigen as well as the small degree of reaction sometimes apparent with the unheated material. These findings confirm Bedson's previous observations on the complex antigenic nature of *Psittacosis*, and suggest that, in the living virus, the heat-stable factor is largely or, less commonly, entirely masked by one or more heat-sensitive components.

Attempts were made to improve the specificity of active, unheated suspensions with various reagents which might preserve and enhance the combining power of the labile antigen or suppress that of the group antigen. At the same time it was hoped that the effects of such treatment might yield further information about the composition of the virus particle.

The heat stability of one factor is very marked, and it was found to resist autoclaving for thirty minutes at 135° C. This property and its lack of sensitivity to a proteolytic enzyme suggest that it may be composed largely or entirely of carbohydrate. Conversely, the other reactive fraction might well be protein in nature.

The serological activity of heated *Psittacosis* was destroyed by 0·001 molar potassium periodate in thirty minutes at 37° C.; the minimal exposure required has yet to be determined. Unheated antigens treated in a similar manner with 0·002 molar solution reacted well with the 'complete' serum; to obtain this effect an increased concentration of virus was required in the test but, even at this strength, no reaction took place between the treated material and the 'group' serum. It would thus appear to have acquired a uniformly specific character.

It has been shown recently[11] that, in addition to its effect on carbohydrates, periodate may alter or inactivate biologically active proteins. Nevertheless, it seems likely that critical dilutions of this reagent may be helpful in the identification of some carbohydrate substrates. The inactivation of the heat-stable *Psittacosis* antigen by periodate is regarded as confirmatory evidence that the group component is, at any rate in part, carbohydrate.

A report giving full details of these and other observations bearing on the antigenic behaviour of *Psittacosis* is being prepared.

Æcidia of Barley Rust in Britain

THE æcidium on *Ornithogalum* species in Europe has an interesting nomenclatorial history. At first attributed to *Puccinia liliacearum* Duby, it was recognized by Bubak[1] as belonging to a separate heterœcious rust and named by him *Æcidium ornithogaleum*. Then, in 1914, Tranzschel[2] demonstrated in both directions its connexion with the common brown rust of barley, *Puccinia hordei* Otth. (syn. *P. anomala* Rostr.). This connexion has been confirmed by Mains and Jackson[3] in the United States of America; but, so far as we are aware, the æcidium has not hitherto been found in Britain. According to Sydow[4], it is known to occur in Germany, Austria and Hungary. D'Oliveira[5], who repeated Tranzschel's experiments and produced æcidia on *Ornithogalum* by inoculation from barley, was unable to find the æcidia in the field in England and concluded that barley rust survives the English winter in the uredo state on barley tillers and seedlings.

On March 14, 1948, one of us (N. Y. S.) collected spermogonia on a leaf of *Ornithogalum pyrenaicum* L. in Inwood Copse near Ham Spray, below Inkpen Beacon, on the borders of Berkshire and Wiltshire within the last-named county. These may have belonged to *P. hordei* or to *P. liliacearum*; but their occurrence stimulated our interest and led to our asking Mrs. F. Partridge, who lives at Ham Spray House and was present when the leaf was collected, to keep a watch for æcidia. Two æcidia were found on April 2, and on April 15 we received from her a consignment of thirty-two infected leaves. Twenty-seven of these bore spermogonia associated with teleutosori of *P. liliacearum*, five bore spermogonia and æcidia but no teleutospores. From the latter, inoculations were made at once to seedlings of common barley (unnamed hybrid seed); and on April 23, uredo pustules were visible on the inoculated leaves. They became erumpent on the following day.

Subsequent careful search of the copse at Ham Spray has shown that *O. pyrenaicum* occurs there in two distinct patches. One adjoins the corner of an arable field which carried barley in 1947; the other lies between fields which carried wheat and oats respectively. The æcidia were found only in the former patch; *P. liliacearum* occurred in both, but mainly in the latter.

While it appears probable that persistence of the uredo stage is the chief method by which barley rust overwinters in Britain, the æcidia may be important in two ways. In the first place, *O. pyrenaicum* is locally abundant (with a discontinuous distribution) in certain parts of the south and west of England and may be responsible for initiating local outbreaks of brown rust. The plant occurs in north Somerset, west Gloucestershire, Wiltshire, Berkshire, Bedfordshire, Norfolk and Sussex. Secondly, presence of the æcidial stage affords opportunity for hybridization between existing physiological races of barley rust and for the production of new ones. D'Oliveira was able to distinguish five races of this rust in England. We suggest that it may be desirable to survey the known stations of *O. pyrenaicum* next April to ascertain to what extent æcidia are normally produced in Britain. Other species of *Ornithogalum*, especially *O. umbellatum* L., should also be examined for this purpose.

We are indebted to Dr. G. R. Bisby for help with the inoculations, and to Mrs. Partridge for her observations and for sending us material.

Velocity of Photons

MR. H. FLETCHER MOULTON'S paradox[1] is ingenious, but easily resolved. The energies of two photons emitted at the same place are *not* equal if each energy is measured in the co-ordinate system of the moving body at which it is absorbed. Each observer measures wave-length and velocity in his own co-ordinate system, and deduces the frequency and energy to correspond. The same remark elucidates the 'mystery' of the Doppler effect; but it must be remembered here that each photon does not show this effect. If one single photon could be received, it would presumably show no Doppler effect (or, indeed, wave-length at all—this is the classical deduction from photo-electric phenomena); the wave decides the probability of the photon being found at any given point, or the distribution of the photons if they are present in sufficient numbers.

DR. GEORGE NOVELLO COPLEY, City Technical College, Liverpool, states that answers to Mr. Fletcher Moulton's questions are given in "A Textbook of Physics", by E. Grimsehl, vol. 5, "Physics of the Atom", p. 240 (Blackie, 1945), where the corpuscular interpretation of the Doppler effect is seen to be analogous to that of the Compton effect.

A NEW INTENSE SOURCE OF RADIO-FREQUENCY RADIATION IN THE CONSTELLATION OF CASSIOPEIA

By M. RYLE and F. G. SMITH
Cavendish Laboratory, Cambridge

THE discovery by Hey, Parsons and Phillips[1,2] of a variable source of radio-frequency radiation in the constellation of Cygnus suggested that at least part of the galactic radiation was due to very intense discrete sources. Afterwards a detailed study of this region was made by Bolton and Stanley[3], using an interference system of greater resolving power; their results showed that the angular diameter of the source was smaller than the resolving power of their apparatus (8 minutes of arc), and the more precise determination of its position enabled them to show that the source does not coincide with any outstanding star. In a more recent note Bolton[4] describes the extension of this work and the discovery of other discrete sources.

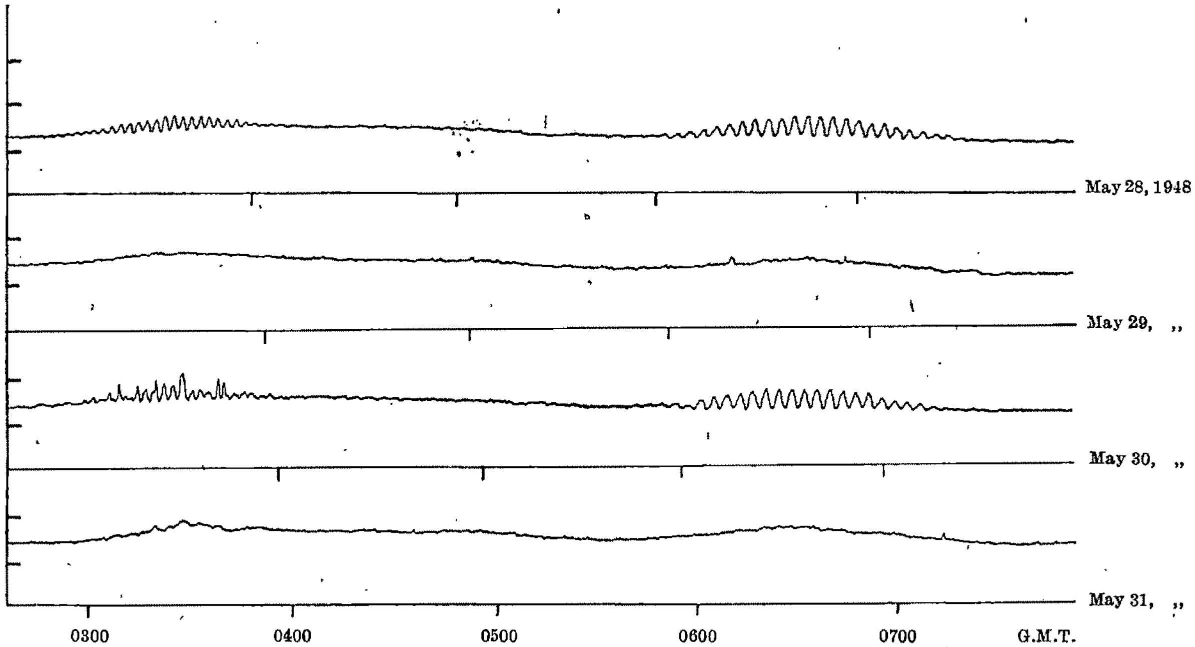
The similarity between the fluctuations observed from the source in Cygnus and from the disturbed sun has suggested to both teams that the mechanism for the emission of intense radiation from discrete galactic sources is likely to be the same as that of sunspot emission. The results obtained by many workers have shown that sunspot radiation is circularly polarized, and it is therefore of importance to measure the polarization of the radiation emitted by discrete galactic sources.

Recently we have carried out a series of experiments on a frequency of 80 Mc./s. to determine the polarization of the radiation from the source in Cygnus. During the course of this work we have found a new and more intense source situated in the constellation of Cassiopeia, as well as several minor sources having a smaller intensity than Cygnus.

In our experiments we have used the radio version of Michelson's stellar interferometer which we have previously described[5,6]. When making observations with a large resolving power, this type of interferometer has advantages over the method used by Bolton and Stanley, since no corrections are necessary for refraction in the troposphere or ionosphere. In order to identify the central maximum on the record we have limited the total width of the interference pattern by using two aerials of considerable directivity. By noting the times of the adjacent minima it is then possible to determine the Right Ascension of the source.

It can be shown that the periodicity of the interference pattern produced on the record by such a system depends on the declination (δ) of the source, and is given by $t_0 \sec \delta$, where t_0 represents the period of the central interference pattern for a source in the equatorial plane. It may therefore be seen that by measuring the period of the interference pattern the declination of the source may be found from the same record, without the need for an aerial system having a large resolving power in a north-south plane.

If the two halves of the aerial system are now mounted with mutually perpendicular planes of polarization, the system may be used to determine the polarization of the radiation from a galactic source. For a wave which is circularly polarized, the amplitude of the interference pattern produced will be the same as with the aerials parallel, but the phase of the pattern will be displaced by a quarter period. If the radiation is only partially polarized, the amplitude of the interference pattern will be reduced, and by comparing the amplitudes obtained with the two aerials parallel and perpendicular to one another, it is possible to determine the degree of polarization. (The full analysis of a complex wave is possible by this method, as has already been mentioned[6].)



Records of galactic radiation using the spaced aerial system (units of intensity are 5×10^{-23} watts/m.^{2}/(c./s.)). May 28, aerials parallel; (2) May 29, aerials mutually perpendicular; (3) May 30, aerials parallel; (4) May 31, aerials mutually perpendicular

We have used an aerial spacing of about 0·5 km. at a frequency of 80 Mc./s. An accuracy in Right Ascension of ± 10 sec. should be possible with this system for sources as intense as that in Cygnus, although our accuracy has been limited by the accuracy of time calibration to ± 20 sec. The determination of declination (δ) becomes inaccurate for small values of δ, but for δ greater than 30° an accuracy of ± 20′ becomes possible.

Observations have been made between declinations of 0° and + 75°. In addition to the source in Cygnus, a more intense source was located in Cassiopeia, the radiation from which has been notable for showing considerably smaller fluctuations than that from the source in Cygnus.

Some typical records are shown in the accompanying figure (curves 1 and 3), in which the interference patterns produced by the sources in Cygnus (0335) and Cassiopeia (0640) can be seen.

The source in Cassiopeia has been found from these records to have a Right Ascension of 23 hr. 17 min. 50 sec. and a declination of 58° 0′ (1948 co-ordinates). The total intensity (twice the value obtained with aerials which accept only one component of polarization) has been found to be 23×10^{-23} watts/m.^{2}/(c./s.), with 'bursts' of radiation having an intensity of up to 6×10^{-23} watts/m.^{2}/(c./s.). The intensity of the source in Cygnus has been found to be 14×10^{-23} watts/m.^{2}/(c./s.) with 'bursts' of intensity up to 20×10^{-23} watts/m.^{2}/(c./s.). The aerial system has not yet been fully calibrated, but although the absolute values of intensity may be in error by as much as ± 30 per cent, the relative values are reliable.

A less intense but more variable source in Ursa Major (R.A. 12 hr. 20 min., declination 58°) has been found to give a maximum intensity of 5×10^{-23} watts/m.^{2}/(c./s.).

The angular diameters of all the sources which have so far been observed are less than the resolving power of the apparatus (about 6 minutes of arc for the two intense sources). The observation of 'bursts' of duration less than 20 sec. coming from the source in Cygnus has shown that the linear dimensions of the source of the variable component cannot greatly exceed the distance travelled by electromagnetic waves in 20 sec. If a source of this diameter (about 10^7 km.) is situated at the distance of the nearest fixed star, the observed intensity would correspond to radiation from a black-body source at a temperature greater than 10^{14} °K.

Observations made with the two halves of the aerial system mutually perpendicular have given records in which the amplitude of the interference pattern is less than 5 per cent of that with the aerials parallel. Some typical records are shown in curves 2 and 4. The results show that, within the limits of experimental error, the steady component of the radiation from both sources is randomly polarized. The determination of the polarization of the variable component of the radiation (see curve 4) is difficult, since the 'bursts' last for a time comparable with the period of the interference pattern, but a study of such records suggests that this component is also randomly polarized.

The detection of intense radiation from discrete galactic bodies has suggested that the radiation is due to processes similar to those occurring in sunspots. The observation that the radiation is not circularly polarized, however, suggests that the mechanism is somewhat different, and may not involve an appreciable magnetic field in the emitting region. The mechanism may possibly be more nearly analogous to the radiation from the undisturbed sun.

VARIATION IN MORPHOLOGICAL AND BIOCHEMICAL CHARACTERISTICS OF ANAEROBIC BUTYRIC ACID BACTERIA

By DR. OTTO RICHARD

Department of Agricultural Bacteriology and Fermentation Biology, Swiss Federal Institute of Technology, Zurich

IN attempts to identify the butyric acid bacilli not liquefying gelatin present in silage-fodder, cow fæces, milk and cheese, we generally found it very difficult or even impossible to determine the exact species of the organisms isolated. In most cases our freshly isolated pure cultures differed, in morphological and biochemical properties, from the species described in literature. Furthermore, one and the same strain, when repeatedly examined, frequently showed great variations with time; a certain strain, which behaved as a representative of the species *a* at one time, later showed the characteristics of the species *b*.

In order to get an idea of the variability of butyric acid bacteria, a great number of strains were isolated from various biotopes and investigated repeatedly. The 260 pure cultures thus examined were isolated from soil, green plants, silage-fodder, fæces of cow and sheep, spoiled process cheese, green cheese of Glaris, Emmentaler cheese, potato-, corn-, rye-, chestnut-mash, and polluted water. Direct isolations by means of smear-cultures on glucose – yeast extract – meat infusion – agar and glucose – yeast water – agar of various hydrogen-ion concentrations were made. In addition, enrichment media were employed, namely skim milk, glucose – skim milk, Winogradsky's solution, glucose – meat – peptone-broth, corn-broth, corn-liver-broth, and pea-broth.

So far the isolated strains have been examined for the following properties: (i) macroscopical appearance of the colonies on the agar media mentioned above; (ii) shape and size of cells and spores grown in various substrates; (iii) Gram-staining and formation of iodophilic substance; (iv) growth and liquefying power on gelatin medium; (v) changes brought about in litmus-skim milk with and without glucose; (vi) ability to ferment sodium lactate; (vii) formation of gas and acid from different carbon sources, namely glycerol, sorbitol, mannitol, xylose, arabinose, rhamnose, fructose, glucose, mannose, galactose, sucrose, maltose, lactose, raffinose, inulin, dextrin, starch, and salicin; (viii) changes brought about in corn-broth; (ix) fixation of atmospheric nitrogen. The results of the present investigation are summarized below.

In young cultures grown under strictly anaerobic conditions several types of colonies can be distinguished. There are colonies with entire margin and those with crenated margin. Frequently root- and hair-shaped projections are formed. Some colonies belong to the flat type, other colonies to the raised type. The colonies of young cultures are generally milky to dirty white, those of old cultures often yellowish or violet. Of special interest is the observation that the ability to form slimy colonies is of erratic nature. On the whole, the variability appearing within one and the same strain in characteristics of the colonies is striking.

Inconstancy also appears in the shape of cells and spores. Thus the different colonies of a strain may contain unswollen as well as more or less distinct *Clostridium*- or *Plectridium*-like rods. Even within one and the same colony, these more or less pronounced types of cells may be found in varying numbers. Young organisms always show motility. The spores are always oval and may have a central to subterminal location, the latter being predominant. In several strains free spores with a brush-like capsule as described by Winogradsky[1] for *Clostridium pasteurianum* were observed in the phase-contrast microscope. Spores possessing such appendages are, however, developed also by strains which have nothing to do with Winogradsky's organism. Special attention may be directed to the fact that the differences observed in appearance of colonies, cells and spores between various strains are not greater than those found, on repeated examination, within one and the same strain.

Young cells are throughout Gram-positive.

According to Svartz[2], the formation of iodophilic substance by butyric acid bacteria under certain conditions is to be considered a property of taxonomical value. The results of the present investigation do not support this view, the appearance of iodophilic substance in the cells being of the same irregularity as that observed in the properties described above. Two strains of *Clostridium butyricum iodophilum* Svartz kindly supplied by him could not be identified by means of the iodine reaction after having been mixed with our freshly isolated strains. Moreover, it was impossible to identify the two strains as a species on the basis of the properties dealt with in the present communication.

All strains show excellent growth but no liquefying power on gelatin medium. The same was the case with a strain of *Clostridium pasteurianum* Winogradsky kindly supplied by Prof. Kluyver, Delft (Holland).

All strains reduced litmus added to glucose – skim milk, generally within 24 hours. At the same time or a little later, a turbulent fermentation, that is, production of acid and gas, started in all cultures. In skim milk without addition of glucose, however, quite different results were obtained. The results of a typical test are seen in Table 1.

Table 1. Effects produced upon skim milk by freshly isolated strains of butyric acid bacilli

Number of strains	Effects
119	Turbulent gas evolution and strong acid production (coagulation)
10	Slight production of gas and acid (no coagulation)
12	Only slight production of acid
27	Slight production of gas without change of acidity
92	No change

Of particular interest is the fact that the activity shown by the butyric acid bacteria in skim milk is very inconstant, the results obtained with one and the same strain at different times, and even with one and the same cell suspension under identical conditions, varying considerably. Further, it is worth noting that there exists no obligate parallelism between the ability of the pure cultures to ferment lactose in milk and the ability to attack this carbohydrate in peptone – meat-broth. On this point our results do not agree with those obtained by van Beynum and Pette[3], who state that strains incapable of producing fermentation in milk do not attack lactose. The same authors state that the butyric acid bacilli may be divided into two distinct groups on the basis of their different ability to ferment lactose and lactate. Thus *Clostridium tyrobutyricum* van Beynum et Pette includes the strains capable of fermenting lactate but incapable of attacking lactose, whereas *Clostridium saccharobutyricum* Beijerinck is supposed to ferment lactose but not lactate. In view of the fact that lactate fermentation is of great importance in cheese- and silage-making, it seemed of interest to test our 260 strains for lactose- and lactate-fermenting power. The method employed was that introduced by van Beynum and Pette[3]. The results may be seen in Table 2.

Table 2. Fermentation of lactose and sodium lactate by butyric acid bacilli

Total number of strains tested	Number of strains fermenting				Total number of strains attacking lactate
	Lactate, not lactose	Lactate and lactose	Lactose, not lactate	Not lactose, not lactate	
260	48 (18·5%)	195 (75·0%)	15 (5·8%)	2 (0·8%)	243 (93·4%)

From the results given in Table 2 it is evident that most strains of butyric acid bacilli ferment lactate as well as lactose. A rather small number of the pure cultures examined attack only lactate, and a very small number only lactose, the former strains thus belonging to *Cl. tyrobutyricum* van Beynum et Pette, and the latter strains to *Cl. saccharobutyricum* Beijerinck. On further investigation, however, it was found that the specificity for lactate and lactose, respectively, is a highly variable property. Thus it could be demonstrated that strains, apparently attacking only lactate, in reality possess a latent power to dissimilate also lactose, and vice versa. Obviously there is no reason for maintaining the species *Cl. tyrobutyricum* van Beynum et Pette. This statement was further confirmed on examining two pure cultures of this organism and two pure cultures of *Cl. saccharobutyricum* Beijerinck kindly supplied by Prof. van Beynum, Hoorn (Holland). Of the former, one strain showed specificity for lactate. The other strain, however, was found to cause a vigorous fermentation of lactose as well as lactate. Both strains of *Cl. saccharobutyricum* attacked lactate.

As mentioned above, the ability of the isolated strains to ferment carbohydrates, higher alcohols, etc., has been studied, this ability often being supposed to be of great importance for the classification of butyric acid bacilli. The results of these tests are shown in Table 3.

It appears that, of the compounds tested, only fructose and glucose are fermented by all strains with simultaneous production of acid and gas. In the medium containing mannose, only one strain failed to induce fermentation. As to the ability to attack the other carbon sources examined, the strains showed great variation, some pure cultures attacking all or most of the compounds, other strains attacking only a few of them. Furthermore, it was found, on repeated investigation, that most of the strains, as regards fermenting power, showed an irregularity of

Table 3. Fermentation of various carbohydrates, alcohols and glucosides by butyric acid bacilli

Carbon source	Number of strains forming	
	Acid	Gas
Glycerol	121	120
Sorbitol	179	187
Mannitol	235	230
Xylose	212	195
Arabinose	221	186
Rhamnose	97	58
Fructose	260	260
Glucose	260	260
Mannose	259	259
Galactose	241	228
Sucrose	224	215
Maltose	229	202
Lactose	211	186
Raffinose	197	195
Inulin	179	173
Dextrin	185	205
Starch	166	172
Salicin	197	163

the same type and the same extent as that found for the other properties examined. For example, one and the same strain on repeated examination of one and the same carbon source may show no attack, attack with production of acid only, attack with evolution of gas only, and finally, attack with formation of both acid and gas.

We therefore agree with McCoy *et al.*[4], that it is impossible to use the fermenting power for the classification of butyric acid bacteria not liquefying gelatin.

According to McCoy *et al.*[4] the butyric acid bacilli not liquefying gelatin may be divided into two groups, called *Bacillus saccharobutyricus*-type and *Clostridium pasteurianum*-type, respectively. Strains belonging to the former group liquefy the starch gel of corn-broth, whereas those of the latter group do not. The results obtained in examining our 260 freshly isolated strains by means of the method described by the authors mentioned may be summarized as follows. Between absolutely inactive strains on one side, and strongly active strains on the other side, there are intermediate types attacking the gel only partially. No obligate parallelism could be demonstrated between starch dissimilation in corn-broth and the breakdown of this polysaccharide in peptone-meat-broth. Furthermore, the power of attacking starch showed the same variability as that observed in the other properties of the strains examined. Thus our results do not support a classification of the butyric acid bacteria not liquefying gelatin on the basis of the changes brought about in corn-broth.

On examination for nitrogen-fixing power in Winogradsky's solution, our pure cultures were found to vary considerably, qualitatively as well as quantitatively. A large number of strains which in their properties, for example, growth on gelatin medium, fermentation of carbohydrates, higher alcohols, etc., are not identical with Winogradsky's organism, induce a turbulent fermentation in the solution without nitrogen compounds.

From the results discussed above the conclusion may be drawn that it is impossible to base a reasonable classification of the butyric acid bacilli not liquefying gelatin on differences in the properties dealt with in the present investigation.

RADIO COMMUNICATION AND THE IONOSPHERE

THE great strides made in the development of long-distance radio communication and broadcasting in the past ten years or so have involved the combined efforts of a large number of scientific workers, engineers and operators. These and older students of the subject have become aware of the fact that the transmission of radio waves to distances beyond the horizon and even right round the earth is only possible because of the existence of the ionosphere, which is that portion of the earth's atmosphere which becomes electrically conducting by ionization chiefly under the influence of ultra-violet radiation from the sun. But while this conducting region reflects radio waves and so returns them to the earth at a distant point, it does not behave as a simple metallic reflecting sheet in the same position at all times and seasons. It is rather in the nature of a series of partially conducting layers, one above the other, each varying in height and conductivity with time, and the lower ones sometimes shielding the upper ones from radio waves transmitted upwards from the earth's surface.

On account of the somewhat complicated nature of this subject, it was found necessary during the War to provide, in a suitable booklet, a background knowledge of the fundamental principles of the transmission of radio waves through the ionosphere for those interested in short-wave communication. Such a book was written by Mr. G. Millington of the Marconi Wireless Telegraph Company on behalf of the Inter-service Ionosphere Bureau and at the suggestion of the Admiralty. It was extensively used by Service Departments during the War, and it seemed to the Admiralty and the Department of Scientific and Industrial Research that the information it contained should be made more widely available for radio technical workers and students. It has therefore now been reprinted with only slight modification as "Radio Research Special Report No. 17—Fundamental Principles of Ionospheric Transmission" (published for the Department of Scientific and Industrial Research by H.M. Stationery Office, 1*s.* 6*d.* (U.S.A., 55 cents), by post 1*s.* 8*d.*).

This report describes the main properties of the ionosphere as a medium in which radio waves from a transmitting station are bent or reflected back to a distant receiving station. The effect of the angle at which the waves are projected from the earth toward the ionosphere is described, together with the influence of sunlight on the transmission, with its resulting possibilities for communication. The text is of a descriptive theoretical nature, and the use of mathematics has been kept to a minimum so that the treatment can be followed by as wide a circle as possible of those interested in this subject.

The book is primarily meant for those who can supplement the reading of it by attending a training course, and perhaps even more for those whose task it is in these days to conduct such courses, and who until now have been handicapped by the lack of any book of the scope of the present one. No reference is made to actual experimental results, such as the values of the heights and critical frequencies of the ionospheric layers, and the diurnal and seasonal variations of these values. The publication admirably fulfils, however, its intended purpose of providing a basis for appreciating and understanding the practical results that can be found elsewhere.

SOCIAL MEDICINE OF OLD AGE

THE Trustees of the Nuffield Foundation have published a report on the social medicine of old age prepared by Dr. J. H. Sheldon in a survey of a random sample of 477 old people*. His object was "to discover the medical and mental condition of old people living at home, and the stresses and strains to which both they and the younger people caring for them may be subject". The survey forms an appendix to the report entitled "Old Age", published by a Survey Committee under the chairmanship of Mr. Seebohm Rowntree. Wolverhampton was one of the towns covered by the Rowntree Report, and the same sample of people has provided the material for the new survey. The town, which has a population of 150,000, was selected because it was large enough to ensure a fair mixture of all income classes and sufficiently compact to enable the compiler to undertake the amount of visiting involved. Old age for the purposes of the survey has been taken to begin at sixty for women and sixty-five for men. The sample was obtained from the register of ration cards, every thirtieth name in the selected age group being included in the survey.

The earlier chapters of the report deal with what the author describes as the natural history of old age, and cover an assessment of the old person's health, ability to move about, the nature and extent of any illness, susceptibility to loneliness, extent of dependence on others for nursing care, shopping, housework and cooking, difficulties in climbing stairs, queueing, moving among traffic or in the dark and liability to fall. The analysis of the physical state of the subjects was based on a case-history supplied by the subjects themselves and by relatives, or in some cases by their general practitioners. No clinical examination of the subjects was possible, and for this reason the data permit no very accurate estimate of the nature of any existing disability. In particular, no precise evaluation can be made of the diseases and functional impairments which are specific to old age, or of the contributory factors involved in the phenomenon of senescence. The remainder of the report makes a valuable analysis of the ecology of old age; that is, its relation with the rest of the community, and the mutual stresses and strains set up.

One of the important points which emerges is the fundamental importance of the family in the social biology of old age. The problems of old people in the mass are domestic rather than institutional. The author favours the provision of temporary hostel accommodation which would enable those normally responsible for their care to obtain occasional relief. Another aspect which is referred to is the provision of old people's dwellings specially designed and carefully sited in building schemes of the future. The possibility of living in the environment to which they are accustomed, of having something to do, and of being still able to feel necessary to the world are of the greatest importance to old people, and may help to explain why the mental level of old people living in their homes appears to be so much better than that of those living in institutions. The sense of loneliness of old people and the disabilities which are inherent in old age are most successfully mitigated where children or relatives live in close proximity. This mode of life seems most satisfactory to both generations since it enables the old people to preserve their independence and the married children to live a separate life, while at the same time ensuring that help is at hand in time of need. There is, however, a darker side to the picture. Many old people, especially women, were found to be carrying a burden in the management of the home, and in some cases in the nursing of a sick husband, which was clearly beyond their capacity. In other cases the care of aged parents imposes a strain on the younger generation which is almost intolerable.

The findings of the report are not necessarily applicable to other towns, and no final conclusions can be drawn from the data which have been obtained. Nevertheless, the report is of value in directing attention to the kind of problems which besets old age and in indicating some of the ways in which these problems can be met. In a population such as that of Great Britain, where the age distribution is moving upwards, there is a clear need for further study of old age.

---

RECENT RESEARCHES ON FOOD

THE first report of the Food Investigation Board since 1938 has only recently appeared*; but readers of scientific journals have been able to follow the work that has been done through the publication of separate papers on particular aspects of the work. The public in general has had a close acquaintance with the results of the work—if not of the work itself—in the war-time dehydrated foods and the special packagings that were adopted. Probably, however, few of those who complained about their dried egg and their household milk realized the amount of work that had gone into making it possible for us to have these foods at all. Here now is a chance for them to learn something of what was done on their behalf, for the successful application of the research findings was the result of close co-operation between the Board and the Ministry of Food.

The present report includes a summary of the work done during the years 1940–45 and a more detailed report for 1946, when the urgency of the war years had lessened and it was possible to resume "a more balanced and diversified programme of research which includes a fair proportion of longer range and more fundamental studies". This year also saw the reopening of the two 'market' laboratories, at Smithfield and at Covent Garden. The Torry Fisheries Research Station had been active throughout.

During the war years problems connected with the dehydration of foodstuffs and their subsequent use took first place—of necessity, since smallness of bulk was of particular importance in transport and storage. Now, however, there is opportunity once again to study such matters as the ripening and storage of fresh fruit and vegetables, the smoking and salting of fresh fish, freezing techniques and the composition of fresh carcases.

The work of the Food Investigation Board covers a multitude of problems arising from the processing, packaging, transport and storage of foodstuffs. Already we are a far cry from the primitive producer-consumer community whose diet is subject to very marked seasonal variations and shortages. All the work described in this report exemplifies man's increasing control over his environment and heralds a time when all foods will be available at all times and always in their most palatable and nutritional forms. (It will make life easy for the dietitians, but I wonder if it may not prove a little dull !)

---

* Food Investigation, 1940–46. Department of Scientific and Industrial Research. Pp. 42. (London: H.M.S.O., 1948.)

However, that time is not yet, and meanwhile much of importance is being discovered. It is only to be expected, in view of the variety of problems that have to be tackled, that progress towards their solution is sometimes held up by lack of data on some fundamental issue. But a glance over the titles of the papers which have been published shows that even under war-time conditions these additional problems were tackled as they came, and in many cases a considerable advance was made in our understanding of the chemistry and physics of biological processes.

One of the most interesting points of advance—and the one which seems to have attracted most attention from other workers—was "the discovery of the reversible formation of starch from glucose-1-phosphate". A preliminary report on this work appeared in *Nature* of March 23, 1940, p. 451. No less important, however, are the contributions in other fields : the study of mucoproteins, of the chemical changes accompanying the development of rigor mortis, the general problem of the denaturation of proteins, the characterization of the components of connective tissue, the cause and cure of the lessening in biological value of milk powder stored with too high a moisture content.

None of this work is reported in full in this publication. For details the reader must refer to individual papers published in various scientific journals (references are given in full). This report is merely the outline picture ; but worthy of attention at that. It is a good example of science applied for the benefit of mankind and of the value of close co-operation between the scientific worker in the laboratory and the trader and administrator in the field. This co-operation was largely brought about by the urgent needs imposed by war-time conditions ; it is to be hoped that it may still be maintained now that the need is less obvious than it was.

M. W. Grant

WORLD ECONOMIC SURVEY

THE broadsheet "World Economic Survey", issued as No. 283 by Political and Economic Planning, gives a very useful and concise summary of two large and valuable reports produced by the Department of Economic Affairs of the United Nations Organisation. This Department is carrying on the essential functions of the Economic, Financial and Transit Department of the League of Nations, which issued almost as its swan song the "World Economic Survey, 1942–44". The comprehensive picture which that report gave of the world economic situation on the eve of victory was supplemented by two other reports, "Commercial Policy in the Post-war World" and "The Cause and Control of Inflation", the former reviewing the problem of post-war trade policies and trade relationships and the latter monetary experience in Europe after the First World War, which especially for their review of the inter-war years are almost equally valuable in providing the background for the discussions of the Economic and Social Council and the Economic Commission for Europe, which it is the prime purpose of the two new reports to provide. These reports, "Economic Report : Salient Features of the World Economic Situation 1945–1947", with a subsequent supplement, and "A Survey of the Economic Situation and Prospects of Europe", are also intended to find their way into the universities and libraries, and the summary provided by P.E.P. will indicate to the industrialist the extent of the assistance they can give them as well as the economist and research worker.

The European survey provides the more precise and detailed body of information ; the most notable feature of the industrial progress of the European countries is the extent to which recovery was retarded in 1947. Agricultural recovery since 1945 has been less satisfactory than in the corresponding period after the First World War, and the volume of food imports into Europe was running in 1947 at about 10 per cent below the pre-war level. The scanty evidence available suggests that, in Europe as a whole, industrial output per man-hour was lower than before the War. The foreign trade of European countries expanded only moderately in 1947 after a rapid recovery in 1946, and an unsatisfactory feature was the sharp decline in intra-European exchanges of food, coal and other essential goods, while trade in luxury products increased. Little hope is entertained that imports of foodstuffs and raw materials can be reduced below pre-war levels, and restoration of equilibrium in Europe's external balance of payments will require a concentrated effort over a period of years. Success depends on the conquest of open or suppressed inflation, the restoration of trade within Europe to pre-war levels and a further expansion of production of the right kind of goods. The survey concludes that, given the continuation of the present high levels of employment, the prospects of attaining the existing production targets for the early 1950's are not unpromising, provided that intra-European trade and credit arrangements can be developed sufficiently to permit a more rational utilization of European resources, and that financial difficulties do not interrupt the flow of overseas supplies.

As regards the rest of the world, while the population is almost 10 per cent greater than ten years ago, food production is still well below pre-war levels, and even if the high hopes for harvests in 1948 are realized, serious deficiencies will remain. Reduction in livestock population is adversely affecting soil fertility and crop yields. Latin-American countries have all suffered from inflation, and the high prices of foodstuffs have lowered the standards of living of many of the inhabitants. Prospects for output and exports of primary commodities other than food in Asia and the Far East are still not very bright, and production, transport and administration will have to be improved greatly before Far Eastern foreign trade is likely to meet the needs of the situation. Areas of Africa which suffered heavily during the War have made marked recoveries, although agricultural output has tended to lag behind the increases in population. Apart from cereal shortages, Africa's most serious problem is the shortage of textiles. The level of industrial production in Australia and New Zealand has been high, but both countries are suffering from shortage of dollars. Both are anxious to continue industrialization, but to do this must promote a high level of immigration. The survey also throws a little light on the disruption of Soviet economy by the War, and the extent of its recovery.

FORTHCOMING EVENTS

Tuesday, September 21—Thursday, September 23

Institution of Civil Engineers (at Great George Street, London, S.W.1).—Conference on "Biology and Civil Engineering".

Institute of Petroleum (joint meeting with the Institute of Fuel, at the University, Edgbaston, Birmingham).—Conference on "Modern Applications of Liquid Fuels".

Tuesday, September 21—Friday, September 24

Institution of Naval Architects (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2).—London Autumn Meeting.

Thursday, September 23

Royal Institute of Chemistry (at the Technical Institute, Darnley Road, Gravesend), at 8 p.m.—Dr. T. W. Parker: "Estimation of Durability of Building Materials".

Thursday, September 23—Saturday, September 25

Faraday Society (at Ashorne Hill, near Leamington Spa).—General Discussion on "The Physical Chemistry of Process Metallurgy".

Friday, September 24

Department of Scientific and Industrial Research, Road Research Laboratory (in association with the Glasgow and District Association of the Institution of Civil Engineers, the Scottish Branches of the Institution of Municipal Engineers and the County Surveyors' Society, and the Scottish Accident Prevention Council, at the Royal Technical College, Glasgow), at 10 a.m.—Conference on "Road Research".

Biochemical Society (in the Department of Biochemistry, The University, Sheffield), at 11.30 a.m.—Scientific Papers.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturers (2) in Engineering—The Registrar, The University, Manchester 13 (September 24).

Senior Technician in the Department of Pathology—The Secretary, Marischal College, Aberdeen (September 30).

Assistant to the Chief Officer of the Official Seed Testing Station for England and Wales, and a Crop Recorder—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge (September 30).

Chair of Pathology in the University of Adelaide—The Secretary, Universities Bureau of the British Empire, 32 Woburn Square, London, W.C.1 (September 30).

Principal Scientific Officer or Senior Scientific Officer (Mathematician) in the Department of Atomic Energy, Risley, Lancs.—The Ministry of Labour and National Service, Technical and Scientific Register, K Section, York House, Kingsway, London, W.C.2, quoting A.312/48A (September 30).

Assistant Lecturer in Biochemistry—The Registrar, King's College, Strand, London, W.C.2 (September 30).

Lecturer in Biochemistry in the Technical Education Branch of the Department of Public Instruction of New South Wales—The Agent-General for New South Wales, 56 Strand, London, W.C.2 (September 30).

Senior Lecturer in Physics in the Leeds College of Technology—The Director of Education, Education Department, Leeds 1 (October 2).

Senior Scientific Officers (with sound knowledge of emission spectroscopy or electronics, or radiation chemistry), and Senior Experimental Officers (well experienced in spectro-chemical or other modern methods of analysis), in the Chemical Inspectorate (Atomic Energy), Ministry of Supply, for analytical work involving modern physico-chemical methods—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, S.W.1, quoting No. 2281 (October 7).

Senior Organic Chemist, Junior Research Chemists (3), and a Chemical Engineer, for the British West Indies Sugar Research Scheme—The Secretary, Imperial College of Tropical Agriculture, Grand Buildings, Trafalgar Square, London, W.C.2 (October 9).

Lecturer in Agricultural Bacteriology, and a Lecturer in Agricultural Zoology—The Secretary, Seale-Hayne Agricultural College, Newton Abbot, Devon (October 16).

Psychologist (non-medical)—The Establishment Officer, Prison Commission, Horseferry House, Dean Ryle Street, London, S.W.1 (October 16).

Chair of Zoology, the Chair of Botany, and a Lectureship in Physics, at Raffles College, Singapore (University of Malaya)—The Secretary, Inter-University Council for Higher Education in the Colonies, 8 Park Street, London, W.1 (October 30).

Senior Lecturer in Botany at the New England University College (University of Sydney), Armidale, N.S.W.—The Secretary, Universities Bureau of the British Empire, 32 Woburn Square, London, W.C.1 (October 31).

Readership in Chemistry at the Royal Cancer Hospital—The Academic Registrar, University of London, Senate House, London, W.C.1 (November 3).

Tutor in Social Case Work in the Department of Social Studies, University of Sydney—The Secretary, Universities Bureau of the British Empire, 32 Woburn Square, London, W.C.1 (November 30).

Chair of Natural History in the United College, St. Andrews—The Secretary, The University, St. Andrews (January 31).

Graduate (young, preferably with honours in chemistry) to join a small research team working on an industrial problem—The Registrar, Loughborough College, Loughborough.

Analyst to take charge of analytical laboratory—The Director, British Paper and Board Industry Research Association, St. Winifred's Laboratories, Welcomes Road, Kenley, Surrey.

Glassblower–Instrument Maker as technical research assistant in physical chemical laboratories, and a Bacteriological Technician for biological section of department of chemistry—The Steward, Chemistry Department, The University, Edgbaston, Birmingham 15.

Research Physicist or Engineer experienced in vacuum and high voltage work, to rebuild and operate a 400-kv. neutron generator and co-operate in biophysical research—The Secretary and House Governor, Mount Vernon Hospital and the Radium Institute, Northwood, Middx.

Geologists and Geophysicists in the Australian Bureau of Mineral Resources, Geology and Geophysics—The Australian Scientific Research Liaison Office, Africa House, Kingsway, London, W.C.2.

Research Chemist for biochemical work on fundamental problems related to the nervous system—The Director, Neuro-Psychiatric Research Centre, Whitchurch Hospital, Cardiff.

Nutritional Adviser for service with the Control Commission in Germany—The London Appointments Officer, 1–6 Tavistock Square, London, W.C.1, quoting F.B.76.

Lecturer in Agriculture—The Secretary, Seale-Hayne Agricultural College, Newton Abbot, Devon.

Associate Professor of Electrical Engineering—The Electrical Engineering Department, College of Engineering, University of Tennessee, Knoxville, 16, Tenn., U.S.A.

Lecturer or Assistant Lecturer in Botany, with special qualifications in Cytology—The Registrar, University College, Exeter.

Assistant Government Chemist in Nigeria, for duties in connexion with water supply investigation—The Director of Recruitment (Colonial Service), Sanctuary Buildings, Great Smith Street, London, S.W.1.

SCIENTIFIC AND TECHNICAL MAN-POWER IN BRITAIN

AMONG the specific issues of policy on which the Advisory Council on Scientific Policy was asked to make recommendations shortly after its first meeting in March 1947 were the arrangements for securing an adequate flow of scientific man-power to meet the needs both of Government and of industry. One section of the Advisory Council's first annual report deals with this problem in some detail, and may well be regarded as the most important section of the report. Since the Barlow Committee recommended in May 1946 that the output of scientific workers should be doubled so as to provide about five thousand every year, it has become apparent that attainment of this expansion within the immediate future is improbable, if not impracticable under present conditions. Furthermore, while on one hand the desirability of an expansion at the recommended rate has been challenged on the ground of the probability of the supply exceeding demand, on the other, fears have been expressed that too large a proportion of the available new scientific talent is being attracted to the Government services and that industry is not obtaining the recruits it requires.

In dealing with this task of keeping under review the probable demand for scientific man-power and the measures being taken to meet it, the Advisory Council on Scientific Policy investigated four primary questions: the number of scientific workers and technologists already available; whether the prospective supply of such men and women in the coming decade is likely to meet the expected demand, and, if not, what further steps should be taken to increase the output; and whether the present distribution of scientific man-power between defence and civil requirements is satisfactory. The last of these is clearly the most important question at the present time; but the answer we give to it must depend partly on the situation revealed by the examination of the first three questions. In regard to the first of these, the Advisory Council has discussed with the Ministry of Labour and National Service the possibility of arriving at a more accurate estimate of the existing number of qualified men of science and technologists than the rough calculation of 55,000 given by the Barlow Committee in 1946. The Ministry doubts whether the Central (Technical and Scientific) Register ever included more than about 85 per cent of the qualified scientific man-power in Great Britain, and the Advisory Council accordingly asked the Ministry to make a new survey with the view of ascertaining the numbers available at the present time.

A large number of replies have now been received to the questionnaire issued at the end of October 1947, and analysis of the results is expected to provide a very useful picture of the scientific man-power now available in Great Britain, with full details of the experience, qualifications and occupations of those covered. Further detailed reviews of the man-power position in particular fields of science are being carried out by the Ministry of Labour, and these reviews should also contribute to the more difficult question of estimating the prospective demand for scientific workers. Some of the recent inquiries, such as that carried out by the Industrial Research Committee of the Federation of British Industries, are admittedly inadequate, and the figure of 70,000 given by the Barlow Committee as the minimum demand for scientific men in the United Kingdom and in the Colonial Service has since been questioned, as well as the further estimate that the effect of raising the school-leaving age and the increasing need for qualified workers in Government service and industry would raise this figure to 90,000 by 1955.

The Barlow Committee estimated that unless the output of newly qualified scientific workers was raised from its pre-war level of about 2,500 per annum to 5,000 we could not expect more than 64,000 to be available by 1955. According to the Advisory Council, the latest figures which have been obtained from the universities indicate that this level has almost been reached and that the present output, if maintained, is therefore likely to meet the anticipated demand. Against this view, it has been stated that the Universities of Oxford and Cambridge will only be able to admit about one in twelve of the student applicants for the academic year beginning this autumn. The Vice-Chancellor of the University of Manchester, Sir John Stopford, has spoken of intolerable overcrowding there, and has told the University Court that the number of students, at present 5,460, might reach 6,000 in October, but after that would have to be kept appreciably below 5,000 until the building programme was under way.

The shortage of accommodation, which has existed since the end of the War, for entrants from school has been due essentially to the policy of giving preference to ex-Service men; but the procedure has naturally reacted harshly on members of the younger generation too young to be called up for several years service in the Armed Forces. The waiting list of ex-Service men with a claim for preference is not yet exhausted, and the majority of those already admitted have still to complete their courses. While this position obtains, even if the standard of acceptances from school reaches a much more satisfactory level than one in twelve, not only must many young aspirants to a university education be disappointed, but also, and equally important for the assumptions of the Barlow Report, the age structure of the intake of scientific workers will be affected adversely, and a longer time will be required before the level is stabilized at whatever figure, whether double or treble the pre-war, for example, may be deemed desirable.

This factor may, however, prove of minor importance compared with the others, such as building extensions and the assembling and training of the teaching and research staff to deal with the increased number of students, which are involved in implementing such a long-term policy as that recommended in the Barlow Report. A Committee appointed by Nuffield College, in its report "The Problem facing British Universities"*, is of the firm opinion that, until additional financial resources can be translated into buildings and equipment, and additional staff collected, the doubling of the university population contemplated by the Barlow Committee is not possible, and even the present increase of a half over pre-war figures is excessive. The provision which the universities can make for other needs—extra-mural teaching, intra-mural part-time teaching, advanced research, and the wide range of advisory work exacted by the Government from university staffs to-day—is stretched to the utmost.

The Nuffield Committee statement casts a very critical eye over the demands for university expansion, and although the Committee appears to be sceptical as to the justification for doubling or trebling the university population, it is unfair to suggest that it is opposed to expansion. It is concerned rather with the best way of dealing with an increased demand in the immediate future, and with the dangers which may result from allowing limited and sectional pressures to distort the balance and scale of university provision. It casts few doubts on the employability of more graduates in the national life; but it is concerned as to the maintenance of the sanctity of university life.

The significant factors with reference to the report of the Advisory Council on Scientific Policy which are stressed by the Nuffield Committee are that the present demands for university expansion represent many conflicting and unco-ordinated pressures. In the aggregate, the estimated requirements of the professions, Government departments and industry for graduates represent a 60 per cent increase on the 1938 numbers. What does not appear to have been considered is how all these demands can be met without fundamentally altering the character and purposes of university education, particularly during the next ten years, when the shortage of teaching staffs is the most critical factor.

It is with this danger in university expansion that the Nuffield statement is fundamentally concerned. It admits the need for expansion, although it reserves judgment as to the magnitude required. It calls for better planning of existing resources, and for more thought about the aims and fruits of a university education. It suggests that before deciding when and how to meet some of the sectional demands for expansion, we should first consider those demands in the light of the fundamental purpose of the university. We may need a re-statement of the principles that should govern the life and work of a university if the demand for training for a career is not to be allowed to distort both the development and the functions of the universities.

The Nuffield statement puts these questions; but it does not attempt to indicate the answers. Its constructive suggestions are designed rather to ease the immediate pressure on the teaching staffs, and two of these are open to serious objection. The proposal to push back to the secondary schools a good deal of the instruction which is at present given in universities runs counter to a fairly general complaint that the schools are already giving much specialized instruction that should properly be given in the university. Certainly any increase in the influence of the university on the content of the school curriculum cannot be viewed without some concern that it may be detrimental to the interests of the many scholars who do not proceed to a university at all.

---

* Nuffield College. The Problem facing British Universities. Pp. 131. (London: Oxford University Press, 1948.) 5s. net.

The second proposal is that universities in Britain should leave to the specialized institutions and technical colleges a good deal of the higher professional training that in the United States is undertaken by the universities. The Nuffield College Committee has in mind particularly the development of advanced schools for the study and teaching of engineering and other technological subjects and for the professional preparation of teachers, clergy and possibly others. The development in the United States as well as in Germany and some other European countries of such specialized institutions for advanced study and research is *prima facie* evidence that the suggestion deserves to be examined carefully. The Massachusetts and California Institutes of Technology and the *Handelshochschulen* of Berlin and Stockholm have assembled staffs and made contributions to research and teaching which few universities surpass. What chiefly distinguishes a university from them is a wider range of studies and a less specialized purpose.

Nevertheless, the separation of the study of engineering and other technological subjects from the universities and concentration in special schools, however closely located to the universities or friendly the association with them, has real dangers. In the first place, segregation of engineering and technological students in this way deprives them of the great benefit of a life shared with students in other fields, and may well encourage the narrowness of outlook so often condemned in the specialist. Conversely, not only have the students of engineering and other branches of technology a contribution to make to the corporate life of the university, sometimes out of proportion to their numbers, but also the teacher and investigator in these fields would, by such segregation, be deprived of the fertilizing and stimulating influence of close contact with colleagues working in such fields as mathematics, physics, chemistry and geology.

The first need, as the Nuffield College Committee rightly points out, is to define the specific function of the university and relate it to the functions of other institutions. In this matter of technical training, too, we need not only to be clear as to the justification for university facilities for any particular branch of professional or technological training, but also we need to recognize much more frankly that most occupations involve so restricted a range of theoretical or scientific knowledge that their technique can be acquired just as effectively and much more economically in the occupation than in a university. That is a consideration which bears closely on the correct distribution of scientific man-power, with which the Advisory Council on Scientific Policy is concerned.

A second conclusion reached by the Nuffield College Committee also touches that problem. Whatever the demands made on the universities, there is no possibility of meeting them unless the universities can draw from the schools a sufficient supply of undergraduates to be trained in accordance with those demands. Earlier in its report, the Committee endorses the view of the Barlow Report that in the present phase of expansion the universities must, so far as they are able, give the first priority to increasing the supply of university teachers and research workers. It then points out in this connexion that the fulfilment of even the sectional professional demands that are being pressed depends on the maintenance or improvement and extension of the general education given in secondary schools, and in particular that the universities must do all in their power to ensure that the schools can secure a regular supply of mathematicians, graduates in English and other languages, the classics and in science.

Complaints have been voiced that just as an excessive proportion of our scientific man-power is entering Government service rather than productive industry, so the staffing of schools with honours graduates in science of high ability is becoming increasingly difficult because of the more attractive and remunerative conditions in industry.

That is clearly a matter to which the Advisory Council cannot be altogether indifferent, although in its present report it merely considers the distribution of scientific man-power between defence and civil requirements. The question of higher technological training has been reserved for discussion in a separate report, and the survey of higher technical and other specialized institutions included in the Nuffield statement should prove a useful contribution to that discussion. The Advisory Council takes up the query raised by the Select Committee on Estimates as to the justification for the present distribution of Government research funds between civil research and defence research, and gives the estimate of about 13,700 scientific workers engaged in civil research as against 5,500 in defence research. The former figure includes 10,000 in industry, 2,500 in civil Departments of State and 1,200 in the research associations. The Advisory Council comments that much defence research and development is carried out by industry, while many scientific workers employed by the Government are concerned with subjects such as aeronautics and radar which have important civil applications, even when research and development are undertaken purely for defence purposes. The comparatively high Government expenditure on defence research as compared with civil research is due partly to the fact that the Government has to undertake directly or by contract all research or development for defence, whereas the main effort on the civil side comes from industry, and partly to the high cost of provision for development, design and prototype production in the defence field.

The Advisory Council has thus only touched the fringe of the general problem of scientific man-power, and in particular the question of distribution deserves rather fuller examination. The estimates of distribution in themselves merit analysis: on the figures quoted, qualified scientific workers employed by the research associations represented roughly some ten per cent of those engaged in Great Britain's total research effort, a proportion sufficiently high to warrant some examination of the question whether it yields a sufficient return in comparison with other forms of research effort. The whole question has a close bearing on the prospective supply, and it may well be found that the promised report on higher technological training will provide the occasion for a more adequate discussion of some of these issues, which require to be resolved before the form of university expansion over the next few decades is finally moulded.

CHRISTIAN HUYGENS

Christian Huygens and the Development of Science in the Seventeenth Century

By Dr. A. E. Bell. Pp. 220 + 7 plates. (London: Edward Arnold and Co., 1947.) 18s. net.

FOR many the most fascinating period in the history of science is the second half of the seventeenth century, the time when the foundations for the vast structures of to-day were laid with extraordinary sureness, solidity and speed. Newton, of course, was the supreme figure, a genius whose pre-eminence has been emphatically avowed by all men of science who have closely studied his achievement. The age was, however, rich in figures of outstanding gifts and accomplishment, and among them Christian Huygens holds a foremost place. He was, incidentally, one of the few to whom Newton paid generous tribute. Pemberton records: "But Sir Isaac Newton has several times particularly recommended to me Huygens's stile and manner. He thought him the most elegant of any mathematical writer of modern times, and the most just imitator of the antients . . .", the "antients" for whom Newton always expressed the greatest admiration. In the "Principia" he refers to "Sir Christopher Wren, Dr. Wallis and Mr. Huygens, the greatest Geometers of our time", and, acknowledging the gift of a copy of the "Horologium Oscillatorium", he writes ". . . Mr. Huygens's kind present, which I viewed with great satisfaction, finding it full of very subtle and useful speculations very worthy of the author. I am glad, that we are to expect another discourse of the Vis Centrifuga." Dr. A. E. Bell, whose book is before us, quotes the familiar "What Mr. Huygens has published since about centrifugal force I suppose he had before me", and adds "wrote Newton with some chagrin", which seems to be a quite unjustifiable comment.

That Newton had a just appreciation of the work of Huygens and fully understood it is significant, because Huygens signally failed to comprehend Newton's full achievement, although he realized Newton's greatness as a mathematician and as an experimenter. He criticized Newton's fundamental work on colour because it did not explain the ultimate nature of colour—"Besides, if it should be true that the rays of light, in their original state, were some red, others blue, etc., there would still remain the great difficulty of explaining, by mechanical principles, in what consists this diversity of colours". He did not understand Newton's "But to examine how Colors may be explained hypothetically is beyond my purpose". Huygens himself wrote little about colour, since the problem as he conceived it, to find a mechanical explanation, seemed to him intractable: "I do not think", he wrote, "that it would be easy to show what makes red or blue colours, nor am I much impressed in this matter by the Cartesian proofs. Certainly it has little or nothing to do with the geometrical method of reasoning."* He may not have been impressed by Descartes' particular views on colour, but nevertheless he himself was seeking a Cartesian type of 'explanation'. Again, he could not accept Newton's gravitating forces acting at a distance; but, although he rejected Descartes' particular way of explaining gravity by swarms of subtle particles, he himself published as late as 1690 a scheme which accounted for terrestrial gravity by a shell of particles round the earth behaving in a somewhat different way from that devised by Descartes. He never, apparently, really understood the essential nature of the advance made by Newton in his great hypothesis of universal gravitation.

To say this is not to disparage Huygens, whose fundamental achievements make a formidable list. His pendulum clock was the first accurate timepiece, and was based upon a thorough mathematical study of the compound pendulum and of oscillations in general; his discussion of centrifugal force constituted a fundamental advance in mechanics; his discovery of the rings of Saturn, a brilliant piece of observation, was conditioned by the great advance which he made in the construction of the telescope; his construction for the wave front by what is known as Huygens' principle is fundamental to physical optics and his treatment of double refraction showed the way for subsequent advances in crystal optics. This, which is only part of his record, is a sufficient performance, without crediting him with the wave theory of light, for which, in the ordinary sense, he can scarcely be held responsible. He is one of the really great figures in physics, and it is quite time that there was a book on him in English.

Dr. Bell's book is divided into two roughly equal parts, the first dealing with Huygens' life and the second specifically with his scientific work. This arrangement has the disadvantage that it leads to a certain amount of repetition, which even extends to a double use of the same phrases and quotations. The biography is simply set down, with a good discussion of the Cartesian influence, which, in spite of the fact that Huygens often disagreed with Descartes on mechanistic details, always remained strong. There is the usual denigration of Hooke: it is, of course, perfectly clear and just that Hooke was incapable of the beautiful mathematical development in which Huygens excelled; but it is not correct to say, as the author does, that Huygens showed as wide a range of activity. I can only suppose that he has forgotten Hooke's work in geology, physiology and architecture, as well as the extraordinary scope of his invention.

The matter of aerial, or tubeless, telescopes is not very clearly handled: the original suggestion came from Auzout, and, so far as I know, no successful use was ever made of them, as anybody who has tried to set up even a model can readily understand. Huygens presented to the Royal Society in 1691 an object glass of 121 ft. focal length, with eyepiece and subsidiary equipment for an aerial telescope. Somewhere about 1844 Admiral Smyth thought of trying to erect it; "the trouble, however, promised to be so much greater than the object appeared to justify that I laid the project aside". The impracticability of the device is not made clear in the book: a plate of the proposed instrument would have helped, and might have replaced, say, that of the Sebastian le Clerc engraving showing Louis XIV visiting the Académie des Sciences, of which the small half-tone reproduction gives little notion. Huygens' philosophical outlook receives some attention. There are many points, such as Huygens' visits to England, on which one would have liked a little more information; but naturally not much detail is possible in the hundred-odd pages devoted to general biography.

---

* "Colores autem quid puniceos faciat aut ceruleos non facile ostendi posse existimo; neque hic multum Cartesianis demonstrationibus permoveor. Certe ad Geometricas rationes minime pertinet."

The chapter that introduces the treatment of Huygens' scientific work contains the remarkable statement: "The history of this mathematical treatment of phenomena is usually somewhat briefly dismissed, as if it all resulted from the insight of Galileo and Newton—and all the rest were fools". I wonder what writers Dr. Bell had in mind when he wrote this and the sentence ". . . it is simply not true that the dawn of the seventeenth century brought a universal belief in the operation of physical law and a discredit of magic and mystical agents". Did anybody ever suggest that it did? Huygens' work on impact is well summarized in one chapter. Very properly, a relatively considerable space is devoted to the "Horologium Oscillatorium", a book which contains, besides a detailed description of the pendulum clock, the fundamental work on oscillation in a cycloidal arc, on evolutes—which stresses the interest of the cycloid—and on the compound pendulum, the researches that established the centres of oscillation and of percussion. As Dr. Bell justly says, the fact that Huygens used geometrical methods instead of calculus for finding the moment of inertia makes this troublesome matter for the average reader of to-day. Incidentally, it has been suggested of Huygens, as it has of Newton, that he himself used analytical methods and afterwards threw the work into geometrical form, as being the gentlemanly way to do things. "Quoiqu'elle y soit exposée en grande partie suivant le style de l'ancienne Géométrie, on ne peut douter que l'analyse de *Descartes* ne soit le principal instrument dont il s'est servi", says Montucla. Dr. Bell also directs attention to Huygens' proposal to use the length of the seconds pendulum as a standard of length. It is not, of course, suitable, depending as it does on g, but it is the first indication of a search for a not completely arbitrary unit. The "Traité de la Lumière" is well handled in a chapter headed "The Wave Theory of Light", although the author properly points out that it is not really a wave theory in the modern sense but rather a pulse theory and that the conception of periodicity is nowhere introduced. The construction for the wave front and the wonderful treatment of double refraction are the fundamental advances made by Huygens. The work on geometrical optics that enabled Huygens to make good—and short, manageable—telescopes is briefly described, as are the Saturnian discoveries and the attempts to 'explain' the earth's gravitational field. A separate chapter is devoted to the posthumous publication, "Cosmotheoros", in which Huygens argued that the planets are probably inhabited. This little book achieved some popularity; it appeared in several languages and an edition of the English translation was published as late as 1757. It is, however, strange that Dr. Bell says nothing of "De Ratiociniis in Ludo Aleæ", a little work on probability of which Todhunter records, "This treatise of Huygens continued to form the best account of the subject until it was superseded by the more elaborate works of James Bernoulli, Montmort and De Moivre", nor of the work on coronæ and parhelia. They are surely worthy of mention, at least.

It is, of course, poor criticism to reproach an author for not having done what he has not attempted, and to many criticisms that might be made Dr. Bell would probably reply that he had not written a book for experienced students of the history of science, but for average readers. This, for example, would excuse the omission of any attempt at a bibliography of Huygens' books. It is, however, scarcely an excuse for the almost complete lack of references to sources or, still more, for the great carelessness shown as to names and dates. In the preface Thomas Power is cited when Henry Power is meant; the letter quoted on p. 45 was written by Sprat and not by Bishop Wren; on a single page the titles of two books by Kepler and one by Bartholinus are misspelt. These are but examples. Every author knows that a certain number of typographical errors are unavoidable, and there is no point in citing the number that this book contains. There are, however, too many bibliographical errors—Schott's "Mechanica Hydraulico Pneumatica" is not mainly about perpetual motion; at one place we are told "In 1674 appeared Hook's *Micrographia* with its astonishing mixture of skilful observation, pregnant intuition and mathematical insufficiency", although the correct date, 1665, is given elsewhere; the date cited for Kepler's "Epitome Astronomiæ Copernicæ" (1635) would make it a posthumous work, the true date of the first edition being round about 1620, and so on. These points are not mentioned in a carping spirit, but as indicating that the serious reader must be careful in taking facts from this book without verification. There is much, in fact, to indicate that Dr. Bell has not spent too much time with the books with which a writer on Huygens should be familiar. The "Short Bibliography" given at the end of the book "limited to comparatively modern publications" is also disturbing. It makes no mention of Bosscha's book on Huygens; the German history of physics that it quotes is one of the oldest and least informative; there are no references given for Huygens' mathematical work; if Delambre's history of astronomy is allowed in as a "comparatively modern" work, then Montucla's history of mathematics undoubtedly earns a place. Incidentally, the issue of Newton's "Principia" quoted as "English translation by F. Cajori 1934" was a re-issue of Motte's translation of 1729, although anyone might be pardoned for overlooking the fact. Complaints about the index are a failing of reviewers; but the index here is really deficient. I have noted well over fifty names that are mentioned in the text, many of them more than once, that are not indexed, and under the names indexed only about half the references that actually occur in the book are cited. Subjects are treated in the same perfunctory manner.

The reviewer would not be thought ungracious. He is grateful to Dr. Bell for having produced a book on Huygens and for having sent him for many hours back to the original sources. The book will be useful as giving a brief and readable account of the work of that great pioneer, and, no doubt, widely read. It does, however, require a thorough revision, however modest its aim may be, and it is to be hoped that, by the time that a second edition is called for, the author will have extended his researches.

E. N. DA C. ANDRADE

SPOT TESTS

Qualitative Analysis by Spot Tests, Inorganic and Organic Applications

By Dr. Fritz Feigl. Third completely revised English edition, translated by Prof. Ralph E. Oesper. Pp. xvi + 574. (New York and Amsterdam: Elsevier Publishing Co., Inc.; London: Cleaver-Hume Press, Ltd., 1947.) 43*s*. net.

ONE of the most striking features of recent developments in qualitative and quantitative analysis has been the increasing use made of micro- or semimicro-methods. This is not, indeed, a modern branch of analysis; some of the old masters worked with very small quantities of materials. Wollaston's laboratory, we are told, consisted at one time of a tray containing watch-glasses, a blowpipe, and similar unimpressive objects, and when he had occasion to need a little calcium phosphate for a blowpipe test, he supplied it by scrapings of an ivory paper-knife. Berzelius created nearly all the chemistry of vanadium with a few grams of material. The so-called spot test, with which the present treatise deals, is also an old friend to most chemists; the use of test-papers and of an external indicator in titrations are examples of its early use.

There comes a time in the history of most branches of science, however, when some enthusiast sees the possibility of large extensions of a method, and by devoted and single-purposed work enlarges the field of some modest plot of knowledge until it becomes an imposing park, stocked with the most bewildering variety of forms. This task has been well performed for the spot test by Prof. Feigl, formerly of the University of Vienna and now in the Ministry of Agriculture Laboratory, Rio de Janeiro, who is well known to all chemists as the leading authority in this branch of analysis.

The book is a complete monograph. It deals with apparatus and technique, with methods, reagents, the exact details of procedure, and the results which may be expected. The field of application embraces metals, acid radicals, free elements, mixtures, organic compounds, and technical materials and minerals. In all cases, the most careful attention to detail is given, so that no user of the book who wishes to carry out any test described in it can have any doubt as to what he must do. Very full references to the literature are given (very few after 1939, and these mostly to the author's own papers), and there is a tabular summary and full indexes.

The reviewer looked up several examples of what might be expected to be found in the book, and was disappointed only once (salicylic acid). In his opinion, the book will find a welcome in all chemical laboratories. The use of spot tests in teaching is a matter on which divergent views will be held, and the reviewer does not think the present book is suitable for general use by students. A separate book, "Laboratory Manual of Spot Tests" (New York, 1943), has been written by Prof. Feigl for this purpose. A feature which struck the reviewer is the extending use which can be made of spot tests in organic analysis; according to the author, this branch of the subject dates only from 1928, and the extensive use of organic reagents in inorganic chemical analysis is also a newer development. Although the remark is not relevant to the present book, the reviewer would like to suggest that more attention should be given in teaching to the reduction in the quantities of materials used in organic preparations by students. There is little point in the teacher in the inorganic laboratory training a student to work with very small amounts of material and with small apparatus when the student, on entering on his training in organic chemistry, is encouraged to work with hundreds of grams and with large bolt-head flasks, as is too often the case because the laboratory manuals specify these quantities. Not only is unnecessary expense incurred, but also the student grows up with an increasing inability to work with the small amounts of material he will normally have available in research work. It has been the reviewer's experience that much of what the student has been taught in the course of quantitative inorganic analysis is undone in subsequent work in the organic chemistry laboratory, where the dirty bench and abundance of material are too often the rule. A short course of work on the lines of Prof. Feigl's manual would do much to restore a sense of proportion.

J. R. PARTINGTON

'HILLBILLY' FOLK-LORE

Ozark Superstitions

By Vance Randolph. Pp. ix + 367. (New York: Columbia University Press; London: Oxford University Press, 1947.) 21*s*. net.

THE Ozark country, or Ozarkland as it is sometimes called, covers some fifty or sixty thousand square miles and extends over the southern half of Missouri, the north-west of Arkansas and a few counties in Oklahoma. Although it is often considered to be a mountainous country, the hills are scarcely more than about two thousand feet, and the country consists of wooded land, gorges and ravines.

The name was first applied to this region by French-Canadian trappers, and the origin of the word is still in dispute, some maintaining that it is derived from Aux Arcs (*bois aux arcs*, wood for bows) and others thinking that it is connected with Azoic Arc. However that may be, the highland country was first settled early in the nineteenth century, and since then, largely owing to the bad soil and poor communications, the region has been to a certain extent isolated, and so has preserved many of the old folk beliefs and customs.

In the present volume Mr. Vance Randolph, who has already written a study of the Ozarks in which he deals with what he calls an "American survival of primitive society", has collected a number of the popular beliefs and practices which are still to be found by the field worker in this region. He attributes the survival of many of these beliefs to the fact that the people made little contact with the outside world since the pioneers came west from the Southern Appalachians. Although many Americans regard these 'hillbilly' people almost as foreigners, the fact is that many of them are of British stock and have been in America since colonial days.

In his discussion of Ozark folk-lore, Mr. Randolph has divided his material into subjects, and the book is really a collection of articles in which the beliefs and superstitious practices of the people are merely assembled without any analysis. In effect, the volume is little more than a catalogue in narrative form, and as such is certainly a useful compilation in view of the well-arranged index. Passing from beliefs on weather signs, the author goes on to discuss matters connected with crops, domestic management and water finders. These water witches or 'witch wigglers' are clearly ordinary water diviners or dowsers, although Mr. Randolph gives no indication that he is aware of these widespread beliefs. Moreover, it is a little difficult to understand why, when seeing one of these dowsers at work, the author should have "shivered" and felt as if the hair was rising on the back of his neck, a fact which he himself explains by maintaining that there was something "uncanny and obscene" about the divining rod.

Much of the folk-medicine and folk-beliefs concerning pregnancy and childbirth could be paralleled elsewhere, and it would be an interesting study to see how far these could be traced to early British sources. Although from what Mr. Randolph has said it would seem that Ozark superstitions are commonly held and of great variety, it would be a mistake to suppose that similar collections could not be made for other regions in which the population has not been cut off to the same extent as those living in Ozarkland. It is true that the superstitions of these less isolated communities would differ radically from those held in the Ozark highlands, but anyone who receives the lavishly produced catalogues of talismans, amulets and charms which circulate in the United States and who reads the advertisements in the newspapers of California and the Middle-West, will conclude that a study of these superstitions would be as entertaining and informative as those of the Ozark country here so assiduously collected by Mr. Randolph.

E. J. Dingwall

RECLAMATION OF THE LAND

Land Reclamation

By P. J. O. Trist. Pp. 178 + 15 plates. (London: Faber and Faber, Ltd., 1948.) 15*s.* net.

THIS book gives an excellent account of problems facing the officers of the war agricultural executive committees in their task of increasing food production during the War. It was essential national policy that as much food as possible should be grown at home, and that so far as possible every acre of potentially good land should be cultivated. But several decades of agricultural depression had left their mark in thousands of acres of land being abandoned or being so badly farmed that in 1939 they made no worthwhile contribution to the national larder. Much of this land was potentially fertile; it was merely costly and difficult to keep in good heart and in many areas it had broken most of the farmers who were trying to get a living off it.

Mr. Trist confines himself to the problems facing the Essex Committee, of which he was first a district officer and then the cultivations officer, in deciding which under-farmed or derelict areas should be reclaimed, and the method of reclamation to be used. The soils involved were mainly heavy clays, either in derelict pasture or thorn scrub, and the work involved included clearing hedges, cleaning out ditches, seeing to the drainage system, and discovering the best methods of doing the critical cultivations before a crop was sown on most of the land. On some, however, the far more difficult problems of bush and scrub clearing had to be undertaken. All the multitude of problems arising from lack of experience, shortage of the proper tools and of suitable foremen for the large unskilled and often unwilling labour force that had to be drafted on to the land are dealt with clearly and at sufficient length for the intelligent general reader to appreciate the difficulties that had to be overcome in successfully carrying out these reclamations.

The book has also a great historical value, for it gives a very good account of the workings of many war organisations, such as the set-up of the county war committees, the difficulties of employing and limitations in using the various types of labour that had to be drafted on to the land, and many other of the day-to-day problems that arise when a great effort is needed to increase food production. Let us hope that the agricultural policy of Great Britain will continue to encourage the farming community to keep all their land at a high level of productivity, so that the lessons learnt during the War will not have to be slowly re-learnt if a future emergency arises.

E. W. Russell

EGG-LAYING BATTERY MANAGEMENT

Eggs from Every Cage

Describing Laying Battery Management. By H. E. Swepstone. Pp. 83. (Worcester: Littlebury and Co., Ltd., n.d.) 7*s.* 6*d.* net.

MR. SWEPSTONE has written a book on laying batteries which should be of great value to the large number of beginners who are interested in this latest system of commercial egg production. The battery system is equally suitable for the domestic poultry-keeper with half-a-dozen birds, the commercial poultry-keeper and the general farmer, so that this useful little book should have a very wide reading public. The author has had twenty years experience of poultry-keeping, and after trying several methods he states that the best of all is the single hen laying battery. In fact, he would rather give up than attempt commercial egg production on any other lines. Surely this is ample testimony of the efficiency of this system.

This book is written by a practical man who has made a success of the battery system, and it provides all the information that the beginner is likely to require. There are excellent chapters and diagrams on the construction of houses and cages, the best way to start and the right management to get satisfactory results. The arguments in favour of starting with day-old pullets, or partly grown birds, are fully explored, and the man wishing to rear his own replacement stock will find the chapter on intensive rearing very helpful.

The method of accounting is well explained; but the figures of costs and returns would be very much more helpful to the beginner if they could have been converted to present-day values rather than pre-war. In his foreword, Mr. Swepstone asks the reader to substitute current prices for those given, and although this may present no difficulty to the experienced poultry-keeper familiar with the trend of prices, it is not so easy for the beginner, to whom the book will have the greatest appeal. Nevertheless, this handy little volume is well written in practical language and should be on the bookshelf of every poultry-keeper.

T. E. Whittle

SOME BIOLOGICAL ASPECTS OF COLONIAL DEVELOPMENT*

By SIR FRANK STOCKDALE, G.C.M.G., C.B.E.
Colonial Development Corporation

CONSIDERABLE interest is being taken by the people of Britain in Colonial development at the present time, and great importance is attached to the further development of Colonial territories in the interests of their inhabitants, the Commonwealth and the world.

In some quarters, extravagant views have been expressed as to the extent and the speed at which deficiencies of foodstuffs and raw materials in Europe can be met from the Colonies; but such views display ignorance of Colonial food requirements, social customs and habits, the poverty of their soils, the vagaries of rainfall, and the hazards from pests and diseases of crops, animals and men. Many of the Colonial peoples themselves are anxious to see the execution of projects which will develop the natural resources and provide them with a wider field of occupation and standards of living; but the road to achievement will only be traversed successfully if there is careful and sympathetic planning and persistent efforts to overcome difficulties.

Government Policy

Government policy is designed to improve and extend the public services and encourage economic progress so far as natural conditions and resources permit. Twenty years ago, a Colonial territory could only obtain financial assistance for active development through a guaranteed loan, but the Colonial Development Act of 1929 and the subsequent Colonial Development and Welfare Acts of 1940 and 1945 provided increasing State help for Colonial territories for post-war plans and centrally administered schemes of research, education and training, and these plans were designed to lead to better nutrition, water supplies, housing and communications, and in turn to better methods of production and higher standards of life.

To secure expanded economic development, the Overseas Resources Development Act was passed in 1948 establishing the Colonial Development Corporation with a capital limit of £110 million, and the Overseas Food Corporation, capital £55 million. The latter is charged with the execution of the East African Groundnut Scheme, and the former is to undertake projects to aid Colonial development generally, its activities covering agricultural, fishing, forestry and mining enterprises as well as industrial, processing and manufacturing undertakings. All projects must be financially sound, and it is the Corporation's intention to supplement, not supplant, private enterprise. It has already a considerable number of projects under consideration, and several have been investigated on the spot. It will start some projects this year, although shortages of basic materials must involve some delays.

Biological Factors

Biological factors have to be taken into account in Colonial development—particularly in Africa.

Population Issues. The increasing populations, their irregular distribution and the drift to the urban areas, emphasize the need for increased production of foodstuffs for local use; and greater occupational diversification is necessary in order to secure a more balanced economy.

Tsetse. Several species of tsetse flies occur on the African Continent and are responsible for the transmission of diseases to man, game, and domestic stock—accounting to some extent for the uneven distribution of populations and domestic animals. The area in which tsetse occurs is estimated to be seventy-five times the size of the United Kingdom. Tsetse flies are found in more than two-thirds of Tanganyika, and outbreaks of trypanosomiasis still occur. Whereas trypanosomiasis is under better control, thanks to increased knowledge and the production of better organic compounds with prophylactic and curative properties, the movement and resettlement of villages is still necessary. Tsetse research work of the past twenty years, including the study of the bionomics of the species and the ecological factors governing their control, has gradually built up a mass of information of the greatest value. It has been established that tsetse flies are susceptible to changes in environment brought about by clearing or thinning the bush, and successful reclamations of areas from tsetse have been achieved by bush clearing, provided that the subsequent tree-growths in the areas so dealt with have been kept in check. Progress, however, is slow, and large-scale clearing operations, such as those being undertaken by the East African Groundnut Scheme, may show the way to bring tsetse-infested country more rapidly into economic production; but no one can be satisfied about the present position. This is recognized by the authorities. Steps have recently been taken to place tsetse research under central direction, and international collaboration is also being secured on trypanosomiasis. Plans are also well advanced for insecticide dissemination by aircraft and helicopters, though the wholesale use of the new insecticides is not without danger, as many useful insects may be eliminated.

Livestock Diseases. In many parts of Africa these remain a factor which controls the development of animal industries and more satisfactory systems of agricultural husbandry. Rinderpest, the most serious of cattle diseases, still occurs in several territories; and although it had been hoped that in East Africa a check had been made on the disease, there have been recent outbreaks in Tanganyika, all the more serious because of the small number of veterinarians at work in the field.

Locusts. Crop losses of considerable magnitude have been experienced in the past in Africa from swarming locusts; but the extensive campaigns for the control of the desert locust in East Africa, and the successful control of the red locust in Tanganyika, have established the fact that locust plagues can be checked before they assume dangerous proportions provided the outbreak areas are supervised and timely action taken against incipient swarms. Spraying from aircraft can be applied effectively, and it has been clearly established that the results of the patient research work of the last twenty years, which are now being applied, are paying dividends.

Termites. Termites still remain unchecked and cause heavy unrecorded losses throughout the Colonial Empire. There is no British authority in the United Kingdom who has specialized in termites and their control, and it does seem high time to provide for a survey of the termite position in

---

* Substance of a paper read before Section D (Zoology) of the British Association on September 10.

Colonial territories and for planned research. The establishment of a post at the British Museum (Natural History) for the specialized study of termites has been recommended; but a team for the scientific study of termites and the evolution of satisfactory control measures is warranted. A considerable amount of local knowledge is available in the Colonies about termite damage and the resistance of certain hard-wood timbers to attack. This knowledge requires to be collated and expanded by scientific research, and control measures need to be more generally adopted.

Pests and Diseases. Pests and diseases of plants and animals are also factors which have to be kept in mind. In addition to rinderpest, I need only mention certain virus and fungus diseases, such as the 'swollen shoot' of cacao in the Gold Coast, the 'sudden death' of cloves in Zanzibar and Pemba, the witches' broom disease of cacao in Trinidad, the Panama and leaf-spot disease of bananas, and then pass on to the pests of cotton.

The need for increased supplies of cotton from within the sterling area is great, especially at the present time. Owing to the research work of the Empire Cotton Growing Corporation and other specialists, many new types of cotton suitable to different areas and resistant to some pests and diseases have been evolved. Crop losses from jassids and other pests and certain virus diseases have been checked by breeding new resistant types. 'Stainers' are troublesome but not limiting; but the red boll worm (*Diparopsis castanea*) is the most limiting, and definitely controls expansion of cotton growing in large areas of Central, East and West Africa where the climatic regime consists of a single rainy season followed by a long severe dry period. Effective agronomic methods have been devised; but the use of insecticides may be necessary before cultivation can be expanded without undue risks in large sections of the continent.

Importance of Food Supplies

We in Britain are well aware of the shortages of food supplies; and in certain Colonial territories the people have not enough for satisfactory nutrition. Insufficiency of the B-vitamins, hungry periods between the seasons, serious shortages when the rains fail, definite protein starvation—particularly in the southern parts of the West African territories—all exist. Throughout the Colonial Empire there is a great need for wider variety in diet and a much greater consumption of protein foods if extra effort is to be expected in developmental projects. In Africa, it is probable that the growing populations will absorb the bulk of meat supplies available in the near future, and Colonial Governments must give the highest priority to the food needs of their people and to the stimulation of increased local production of crop and animal products.

Fishing. The fishery resources in the waters of Colonial territories have been neglected too long, and a wide field is open for development by the application of modern technology. The first stage is to establish a measure of the availability of fish in terms of the yield per unit of human and material effort expended in their capture and distribution, and then determine the level to which exploitation can safely be developed. Practical tests are an urgent need.

At a later stage it will be necessary to build up a body of basic scientific knowledge of the fisheries so that the level to which exploitation can safely be developed can be determined.

An ambitious programme of research has been planned, including the development of freshwater fisheries and the establishment of fish farming in several areas. There are obviously vast possibilities of increasing fish supplies by fish farming, and a Government training and research centre is to be established in Malaya.

The whaling industry has been developed largely as the result of the whale fishery investigations of the "Discovery" Committee of the Colonial Office. This industry is an example of complete dependence on fundamental oceanography and marine biology. Through this work the vast biological productivity of the southern oceans is made available for human needs, with a reasonable assurance of a maximum sustained production.

Mechanical Aids to Colonial Agriculture

Colonial agriculture is dependent largely upon peasant producers—many of whom grow their crops on small areas for subsistence purposes. In the main, their husbandry methods and animal industries can be greatly improved, though with the existing tools and the methods in vogue increased productivity is difficult to achieve. The requirements at present are to secure better organisation of farming operations and to test the value of fertilizers and mechanical aids. The effects of the introduction of mechanical implements on the farming economy and the social organisation of the people will require careful study and investigation, as their introduction will necessitate farming units of a larger size, whether cultivated individually or communally. The possibilities of increased soil erosion and dangers from pests and diseases must not be overlooked. Useful lessons will doubtless be learned from the East African Groundnut Scheme.

The East African Groundnut Scheme

There is no doubt that the world shortage of edible oils made it essential that this project should be undertaken. It will have an important influence on the agriculture of Tanganyika and on Colonial development generally. I have recently had an opportunity of paying a short visit to the Kongwa area, where the speed at which equipment could be assembled for bush clearing, cultivation and harvesting has been much slower than had been anticipated. Much of the equipment had to be reconditioned or modified and some new implements evolved; but many of the technical difficulties on the mechanical side have now been overcome, and those responsible are to be congratulated on their achievements. Unforeseen difficulties had to be expected and allowed for—this is always the case in pioneering ventures—but the groundnuts and other crops this year have been free from any serious attacks from pests in the Kongwa area, except for damage to the sorghums in the experimental area. There has been some loss of certain groundnut varieties from wild pig; but no occurrence of the virus disease, rosette, which is capable of causing serious losses, has, so far, been detected. It is very necessary, however, that the research work undertaken by the scheme should be well in advance of requirements, so that outbreaks of rosette and of other pests and diseases can be met when they arise.

An extensive programme of field trials to investigate crop rotations, fertilizer needs, cultivation methods and groundnut varieties, as well as a large series of observation plots with a wide range of crops have been put into effect this year, and valuable lessons have already been learnt. This work has been given the highest priority, and steps have recently been taken to increase the scientific staff. It is to be hoped that arrangements will also be made for the testing of a wide range of groundnut varieties for resistance and immunity to rosette disease in an area of the territory where the disease occurs in some abundance, as in my view such work can only be regarded as a necessary insurance.

Conclusion

A considerable increase of basic knowledge is being built up as the result of Colonial research work; but there are still gaps in our knowledge. The application of the results of research work also leaves much to be desired. The strengthening of the staff of the British Museum (Natural History) appears to be desirable in the interests of Colonial biological research. Termites, in particular, require further study. It is also necessary that early steps be taken to enable Kew to produce a Flora of East Africa. Such a Flora is not at present available, and its production is essential for further ecological work in the East African territories and for the use of biologists working in these territories.

HIGHER EDUCATION IN THE COLONIES

IT was a graceful gesture by the Sixth Congress of the Universities of the British Commonwealth to devote its concluding session on July 23 at Oxford to a discussion of higher education in the Colonies, and thus to recognize and welcome the youngest members of the academic family.

The discussion, under the chairmanship of the vice-chancellor of the University of London, Prof. Hughes Parry, was opened by Sir Alexander Carr-Saunders with a sketch of the general plans for developing university institutions in the British Colonies and in the Sudan. In addition to the two existing Universities of Malta and Hong Kong, there will soon be, in Malaya, a third university if the proposals of the recent commission are adopted for the fusion of the King Edward VII College of Medicine and Raffles College. Five new university colleges are being established, two on the basis of existing institutions, Gordon Memorial College, Khartoum, and Makerere College, Kampala, serving the East African territories, and three as new foundations, University College, Ibadan in Nigeria, the University College of the Gold Coast, and the University College of the West Indies in Jamaica. These five university colleges are autonomous corporations, governed by councils the composition of which ensures that they are broadly representative of the interests concerned in their territories, including Government, and include an effective proportion of academic staff representatives. Control of all academic matters is vested in academic boards, composed wholly of members of the staff. The students at these colleges will sit for the degree examinations of the University of London, with which the colleges will be "in special relationship". By this arrangement, the University of London, while retaining complete control over the award and standards of its own degrees, is prepared to devise, in consultation with the colleges, syllabuses appropriate to the needs and opportunities of the territories and to associate the local staffs in the setting of papers and marking of scripts in the examinations. After gaining experience in constructing syllabuses for special degrees, in conducting local examinations and in establishing firm standards, the colleges will in due course seek degree-granting powers and become independent universities.

A sum of six million pounds from central funds administered on the advice of the Colonial University Grants Committee is available as a contribution towards the capital needs of this programme (excluding the developments in the Sudan). Grants for recurrent expenditure will have to come chiefly from the local governments, and arrangements are being made for such assistance to be given as block grants for quinquennial periods to ensure a proper degree of independence for the colleges. Academic assistance, technical advice, library services and co-operation in a variety of ways from the home universities is provided through the Inter-University Council for Higher Education in the Colonies. The critical need in the next phase of carrying through these plans for a new university and five new university colleges is for properly qualified staff. The conditions of service, the salaries, the academic freedom, the research opportunities, the responsibility of the work make service in these university institutions attractive, and every effort is being made by Inter-University Council visits and other means to overcome some of the disadvantages that formerly existed in Colonial work such as the relative isolation. Sir Alexander Carr-Saunders concluded by appealing to the Dominion universities to interest members of their staffs in serving in the Colonial institutions, either in permanent appointments or on temporary secondment.

In the discussion which followed the opening address, Mr. Lewis Wilcher, principal of Gordon Memorial College, and Dr. Kenneth Mellanby, principal of University College, Ibadan, paid tribute to the assistance given to their colleges by the Inter-University Council and by the University of London. Mr. Wilcher reported that Gordon College hoped to obtain independent university status within ten years, and emphasized the value of the services which higher education had to render to the Sudanese in their rapid progress towards self-government. Dr. Mellanby stated that University College, Ibadan, was beginning in temporary buildings near the permanent site of five square miles which the Nigerian Government had presented, in addition to making a contribution of £500,000 towards the recurrent expenditure of the College in the first quinquennium, and an initial grant of £250,000 to an endowment fund. The College would have two hundred students in residence for the session 1948–49, and expected an annual intake of a hundred. Local groups were springing up throughout Nigeria to collect funds to be placed at the disposal of the College for awarding scholarships.

Mr. H. R. Raikes, vice-chancellor of the University of the Witwatersrand, hoped that the Colonial medical schools would ensure that the students' training made full use of the special opportunities provided by the local clinical material and experience, and pleaded that dentistry should be treated as of equal importance and urgency as medicine; he suggested that external examiners going to the Witwatersrand from the

United Kingdom should be encouraged to visit the Colonial medical schools *en route*. Dr. E. G. Malherbe, principal, Natal University College, stressed the dangers of mass literacy campaigns and elementary education in Africa in exposing the peoples to irresponsible propaganda and to some of the less-desirable features of Western civilization if they were not accompanied by the parallel process of providing the enlightened leadership and critical interpretation which the Colonial university institutions would give.

Dr. J. W. Davidson (Wellington University College, New Zealand) directed attention to the danger of importing into the Colonies European standards and conceptions of university education insufficiently adapted to the conditions and interests of the local communities, and thus losing deeply rooted popular support for the new colleges. Prof. A. R. Humphreys, of Leicester, suggested that a practical step to remove one of the deterrents to recruitment, namely, fear that it would be difficult to return to home university posts, would be the prompt and systematic notification of appropriate vacancies to staffs serving overseas.

Principal H. J. Page described the activities of the Imperial College of Tropical Agriculture, Trinidad, the primary task of which is postgraduate training in tropical agriculture of students entering the Colonial agricultural services; a secondary function has been training students, chiefly from the West Indies, for a local diploma. The College hopes soon to co-operate with the University College of the West Indies in providing teaching for the London degree in agriculture. Mr. Bernard Williams, dean of the Medical School, described the plans for opening the Faculty of Medicine of the University College of the West Indies in October, the special problems created by the scattered territories of the West Indian Colonies, the assistance which the College had received not only from the Inter-University Council and University of London, but also from McGill University, and the methods by which it was hoped to overcome the technical difficulties in the secondment of clinical teachers.

Prof. W. E. Dyer, principal of Raffles College, Singapore, stressed the importance of the secondment of university teachers to the Colonial colleges as a means of reducing the isolation and fear of loss of academic status of the local staffs. Prof. F. L. Warren, Natal University College, considered that one reason why a greater number of French than British scholars had remained in service in Egypt was that staff seconded there from the Sorbonne or University of Paris were granted in two years the seniority which would accrue from three years service in France; he suggested that the overseas institutions would attract visiting specialists if they made it known that they could offer working facilities and cheap residential accommodation, such as were provided for visiting astronomers and marine biologists in Egypt.

Prof. Lillian Penson, of the University of London, in concluding the discussion, stated that every effort was made, through full consultation with local opinion and by other means, to harness the sympathy and support of the peoples to their university colleges, and that, far from any forcing of standards by the University of London or the Inter-University Council on the local communities, the demand for the highest standards and nothing less came from the peoples themselves. Secondment on temporary service to the Colonial colleges gave an opportunity of attractive work; from her knowledge of the quality of Sudanese students, she felt confident that staff need have no fear of lowering standards; and the risk of isolation or of being lost sight of was greatly diminished by the work of the Inter-University Council, particularly by its regular visits.

ROCKEFELLER INSTITUTE FOR MEDICAL RESEARCH, PRINCETON

By Dr. J. A. V. BUTLER

Many scientific workers will have heard, with regret and possibly incredulity, of the impending closing of the Princeton Laboratories of the Rockefeller Institute for Medical Research. The decision to close these Laboratories and to concentrate the work of the Institute in New York was reached in the spring of 1947. The Laboratories are to be closed by 1951; but if an acceptable offer for the site and plant is received before then it will be accepted. Any members of the staff who wish to do so may continue their work in the New York Laboratories.

It would be impertinent to question the reasons which have led to this decision; but friends of the Laboratory, as well as many who have been privileged to receive its hospitality, will be distressed that it should be necessary. The founding of the Princeton Laboratories was a logical consequence of the policy of the Rockefeller Trustees to provide facilities for the study of disease in all its manifestations, in animals and plants as well as in human beings. This policy was magnificently justified by the results achieved, and to an onlooker it seems a grievous and deplorable loss to science that it should be found necessary to reverse it.

The Rockefeller Institute began its work in a temporary building under Dr. Simon Flexner in 1904. The present New York buildings on a site overlooking the East River were begun in 1906 and have provided both a hospital for the study of special diseases and a wide range of laboratories covering all branches of biochemistry and physiology.

The policy of the Trustees to study disease in all its forms led to the establishment in 1914 of the Department of Animal Pathology with laboratories on a country site near Princeton, under Dr. Theobald Smith, who was succeeded in 1930 by Dr. Carl Ten Broeck. In 1931 the plan to provide, in one organisation, for the study of disease as it occurs in all the main orders of living things was completed by the addition to the Princeton establishment of a Laboratory of Plant Pathology. The Princeton Laboratories also housed a Laboratory of General Physiology, under Dr. J. H. Northrop, which has devoted itself to investigations of the nature of enzymes and other biologically active proteins of animal origin.

The world-wide reputation of the Princeton Laboratories was based in part on the isolation of a large number of crystalline enzymes and their precursors in Dr. Northrop's laboratory, and on Dr. W. M. Stanley's isolation of the tobacco mosaic virus and succeeding studies in the Department of Plant Pathology. Although the first isolation of a crystalline enzyme was achieved by Sumner in 1926, it is not too much to say that the work of Northrop and his colleagues, leading to the purification and crystallization of a long series of enzymes and related substances, has done more than that of any other group to open up the chemistry of enzymes; while, as is well known, Dr. Stanley's work decisively initiated the modern studies of virus particles. Numerous discoveries in animal pathology were also made within the laboratories, for example, Shope's rabbit papilloma, and many others, which the writer regrets he is unable to describe adequately.

It is most regrettable that the staff and equipment by which such results have been achieved should be dispersed. The main reason for the decision is apparently the contraction of the funds available and also a desire to concentrate the available resources on the Hospital and its auxiliary laboratories. It is understood that attempts made to enlist sufficient financial assistance to make possible the continuation of the Laboratories as a scientific unit were unsuccessful. Many of the younger members of the staff and some senior ones have already accepted posts elsewhere.

The result is the dispersion of a most valuable scientific establishment, which made a contribution to biological and medical research of unique importance. Situated a few miles from the university town of Princeton and within easy reach of New York, it was an ideal site for scientific work. The many British workers who enjoyed its hospitality will remember the efficient organisation of its well-equipped Laboratories and the friendly and agreeable atmosphere of its club-house, and will regret its passing acutely.

RADIATIONS AND HEALTH

A DOSE of radiation above the accepted tolerance limit of 0·5–1 roentgen per week presents hazards to the individual, notably those of sterility and cancer, and to his progeny—in the form of recessive mutations. The importance of the former effects has been recognized since the beginning of the century mainly as a result of the all too obvious injury to many of the early workers with radium and X-rays. The medical profession is therefore fully alive to these dangers. On the other hand, whereas the practitioner sees many examples of the effects of recessive mutations in man—the amaurotic familial idiot, the hæmophiliac, the alcaptonuric—he is seldom, if ever, able clearly to relate these to radiation effects. Thus the matter of genetic damage stands outside the field of practical medicine, and indeed so far has been largely a theoretical concern of eugenics.

Several new factors are at work which must ultimately alter this position. One is the recognition, now beyond dispute, that the genetic effects of radiation are cumulative. The increase in the mutation-rate is proportional to dose, no matter how long may be the period over which it is accumulated. It is estimated, for example, that a dose of 50 r. doubles the mutation-rate in man[1]. It will be noted that the tolerance dose, if regularly received over a reproduction life-time, represents approximately 750 r. It is in no sense a threshold value, and finds general acceptance only on the understanding that not more than 1 per cent of the population receives it regularly. In these circumstances the genetic effects are reckoned to be not more serious than other inevitable ones. The same effects would be produced by a dose of 75 r. incident on 10 per cent of the population. Another factor is a fuller realization of the high levels of radiation to which the population is being subjected as a result of the increasing popularity of X-rays and radium in a wide variety of uses. Especially is this true of the diagnostic and therapeutic uses. At one extreme, doses of the order of 10,000 r. are given in the deep X-ray treatment of malignancy, fortunately to sterile patients, and at the other a diagnostic screening after a barium meal accounts for 10–15 r. delivered directly to reproductive cells. Between the two stand a variety of conditions not in themselves fatal for which radiation is used; for example, ringworm and warts, and especially sterility in women, and on top of them come new treatments with radioactive isotopes. Finally, and most important of all, there stands in the background the sinister threat of an atomic war.

From the points of view of cancer and sterility, it is clearly in the interests of everyone to see that his accumulated radiation dosage both to tissue and reproductive cells is kept at the lowest possible level. He cannot know what the future has in store for him. From a national point of view, it is equally imperative that the level of peace-time radiation should be kept low. The people will be proportionately better able to tolerate the higher doses associated with preparation for, or the actuality of, an atomic war. The ultimate survival of a nation, if not indeed of the population of the world, may depend on just such a piece of elementary prudence as this. Peace-time levels cannot be ignored on the grounds that they are insignificant in relation to the radiation energy which may well be released in an atomic war. As Muller[2] has pointed out, much of the latter will not reach humans at all, and of the proportion which does, most of it will kill outright or sterilize. The insidious danger to the survival of the population lies in the breeding residuum, which will contribute a large number of recessive mutations to future generations. If these are already dangerously undermined in their genetic material by a wanton peace-time use of radiation by their forbears, the results will be serious.

These considerations require as a very minimum that public and scientific attention should be directed to the field of radiations and health in the broadest sense. In some measure, with this end in view, the Radiology Section of the British Medical Association at its Cambridge meeting held a symposium on the therapeutic applications of radioactive isotopes. The physical basis of the subject was presented in an opening paper by Prof. O. Frisch (Cavendish Laboratory), who dealt in particular with the various nuclear reactions which lead to the production of radioactive isotopes. Dr. A. S. McFarlane (National Institute for Medical Research) followed with a review of recent tracer applications, emphasizing the opinion that greater ultimate advantage will probably accrue from biochemical applications with the discovery of precise metabolic pathways in view, rather than from the more spectacular non-specific uses, as, for example, to measure blood-cell volumes or thyroid function.

The main contribution came from Prof. J. S. Mitchell, occupant of the newly created chair of radiotherapeutics in Cambridge. From his wide review covering all isotopes used therapeutically by external and internal administration, it is perhaps justifiable to refer in particular to his statements in relation to sodium-24, phosphorus-32, and iodine-131. These isotopes are usually administered internally, the first two being especially hazardous because, unlike most forms of therapeutic radiation, by virtue, of their widespread distribution, they affect both reproductive and somatic cells. Iodine, on the other hand, is localized to the extent of 80 per cent in the thyroid gland, and this enables doses of 5,000 r. to be given which are effective in destroying glandular tissue in hyperthyroidism. The method is not to be preferred to surgery; but has a useful field of application where other considerations preclude surgery, or in recurrences after surgery. There is a definite risk of late carcinogenesis which is generally worth taking. Few thyroid carcinomas take up useful amounts of iodine, so that isotope therapy is of little value in most malignant conditions of this gland.

Phosphorus-32 given as inorganic phosphate spreads widely throughout the body. Although it is an important constituent of nucleic acid, and practically all tumours are highly nucleated, the differential concentration never approaches that of iodine in the thyroid and generally is too low to be therapeutically useful. However, supplementary X-rays may be used. Prof. Mitchell stressed particularly the value of chemotherapeutic research directed to the synthesis of phosphorus compounds which will become localized in tumour cells. The concentration factor may be increased by local injection of the drug, and the biological half-life of the isotope may be prolonged. The latter incidentally is a composite function of the physical half-life and the excretion-rate. For phosphorus-32 it is estimated to be 11 days for body phosphorus and 6·3 days for thyroid iodine, which compares with physical half-lives of 14 and 8 days respectively.

Phosphorus finds its most effective application in generalized conditions, such as polycythæmia vera and the leukæmias. For the former it is now the treatment of choice, 6–8 millicuries being sometimes effective in a single dose. Generally, however, the disease is kept in control by repeated treatments. The isotope is easily given, the results are better than with external radiation and there are no toxic reactions. It is of interest to note from the hazard point of view that a single dose of 8 millicuries of phosphorus-32 equally distributed in a 70 kgm. adult delivers 70 r. The danger may be observed by the fact that 10 per cent of polycythæmia cases in any event develop into chronic leukæmias; but a few acute leukæmias have been observed after phosphorus treatment. Here again, in Prof. Mitchell's view, the general clinical picture usually justifies the risk.

The initial popularity which phosphorus-32 enjoyed in the treatment of myeloid leukæmia seems to be passing. The high doses used are associated with serious risk to reproductive organs, bone marrow and lymphoid tissue. Most of the isotope is ultimately excreted through the kidneys, and insufficient information is available about remote renal effects. Isotope treatment without supplementary X-rays is valueless in lymphadenoma (Hodgkin's disease), in acute leukæmias of any kind and in tumours. The same remarks apply to sodium-24.

A lively discussion followed, from which it was obvious that the audience much appreciated in particular Prof. Mitchell's survey and shared his cautious attitude in the present limited state of our knowledge. Among various hazards discussed was that arising from the inhalation of particulate radioactive matter. This is present, for example, in laboratories carrying out incinerations of carbon-14 compounds. A minute amount of isotope may ultimately exceed the carcinogenic dose at a point of focus in the lung, since the physical half-life is much longer than the life-span of the individual.

OBITUARIES

Mr. P. J. Barraud

It is with deep regret that many of his friends and colleagues will have received the news of the death on August 9, after a long illness, of Mr. P. J. Barraud, at a nursing home at Bournemouth. I first came to know Mr. Barraud, as did a number of others in the Government of India Bacteriological Service, as entomologist attached to the Central Laboratory, Busra, during the latter part of the Mesopotamian campaign in the First World War; but he had earlier in the War done valuable work in the R.A.M.C. in Salonica and Palestine, where he received his commission as captain. Later, in 1922, Barraud was appointed entomologist on special duty under the Indian Research Fund and attached to the Central Research Institute, Kasauli, to carry out research and make a comprehensive survey of the culicine mosquitoes of India, a subject which at the time was very much in need of revision.

Between 1922 and 1932 Barraud published some forty papers describing systematically group after group of mosquitoes with descriptions of large numbers of new species, the final results being published in 1934 as the volume in the Fauna of India series, "Megarrhine and Culicine Mosquitoes of India", a work which was almost unique in its scope and clarity of treatment and which still remains the most comprehensive treatise on Oriental Culicidæ yet published. From at most a few score of recognized species Barraud's work resulted in the description of the adults and early stages of nearly 250 species. At one time he had some difficulty in finding names for all the new species he was describing, and at the present time, out of about 250 total species known from India, more than sixty will be found under Barraud's name as describer.

When in 1925–27 the Kala Azar Commission was formed to investigate the method of transmission of this disease, Barraud was selected as one of its members, and during the time that the Commission was at work he contributed many papers in his own name and jointly with that of other members relating to kala azar and the sandfly *Phlebotomus argentipes*. Besides his more purely laboratory work, Barraud took a great interest, and played an active part, in the training of officers and other staff in the malaria courses held at Delhi by the then Malaria Survey of India (now Malaria Institute of India), and in this connexion he was the author of a very helpful practical entomologist's course for students of malariology (Health Bulletin Series No. 18, published by the Government of India).

After his retirement at Colehill and until his health failed, Barraud played a very active part during the Second World War in local salvage and other local war activities, and was vice-chairman of Colehill Parish Council. He was not only very highly esteemed by his colleagues in India, but also remained the friend of many of them up to the time of his death. His unassuming kindness and interest in those he came in contact with made him a general favourite socially, and he was a very fresh and companionable friend. He entered with zest into the work and interests of those whom he knew and would take endless trouble to help where his services could be brought usefully to bear. S. R. CHRISTOPHERS

Prof. C. Perrier

NEWS has been received of the death of Prof. Carlo Perrier, professor of mineralogy in the University of Genoa, Italy. Prof. Perrier was born on July 7, 1886, in Turin. He studied in that city and obtained his doctorate in chemistry at the University of Turin. Shortly thereafter he worked for some time in the laboratory of Baur in Zurich on physical chemical problems. On his return to Italy his interest turned to mineralogy, and he joined the school of F. Zambonini.

In 1926 he became professor of mineralogy in the University of Messina, and later he moved to Palermo and finally to Genoa. His work was mostly on crystallochemistry, and he brought to it a remarkable analytical skill and a deep knowledge of crystallography.

Perrier had a wide range of interests and a versatile mind, and when the occasion arose, he was quick to apply his various skills to new problems. Noteworthy among these were the study of technetium carried out by radioactive methods in Palermo in 1936–37 and the investigation by radioactive tracers of some biological and chemical problems. His merits were recognized by membership of several Italian learned societies, including the Academy of the Lincei.

He was a loyal friend and a good teacher, and his untimely death will be deeply regretted by everyone interested in the future of science in Italy.

NEWS and VIEWS

St. Anthony's College, Oxford

AN anonymous Frenchman has given £1,250,000 to the University of Oxford for the foundation at once of a new residential college, with the ordinary status of an Oxford college. Its name is to be St. Anthony's; and its head is to be called the 'warden'. It will start with seven or eight fellows and about fifty graduate and undergraduate members. It will be governed at first by the warden and fellows in conjunction with a St. Anthony Foundation, called into existence recently to carry out the benefactor's wishes. It will be accommodated in the first large house with grounds that can be secured in the vicinity of the University, so that this generous new venture may become visible in the life-time of its founder. He himself has little connexion with England and none with Oxford. His name, if disclosed, would convey nothing to the academic world; but, like Cecil Rhodes, he has admired Oxford men in positions of responsibility all over the world, and has become convinced that the British system of education has promoted initiative and strengthened the moral qualities of students better than any other. Again, like Rhodes, he is anxious that men from overseas should go to Oxford. He has asked, therefore, that in the new St. Anthony's College a substantial proportion of the places available should be kept for qualified graduates from French universities. To encourage undergraduate members to come from France in far greater numbers in the future than they have done hitherto, he has offered a further £250,000 to be divided among any existing Oxford colleges that propose to build additional sets of rooms for their men, provided that in these new sets one third of the places are kept for Frenchmen.

The new proposal was welcomed in a hastily summoned Congregation at Oxford on September 15. St. Anthony's will have the uphill task of all new educational institutions at the present time; but if it contributes something fresh and vigorous to Oxford academic life, as have all the colleges founded in the past hundred years—the five women's colleges, Keble and Nuffield Colleges and St. Peter's Hall—it will do good work. It is a mistake to think that Oxford has all the colleges it needs and that benefactors would be wiser in giving their money to the University itself for furthering teaching and research than to the colleges to strengthen their tutorial system and collegiate activities. This is exactly the time when new colleges are wanted and when some of the existing colleges need further endowment if they are to retain to the full the tutorial system that is so excellent a part of Oxford life. Relative to even the richer colleges, the University in its role of promoter of teaching and research is very well off. It has its own endowments. It has a substantial income from the colleges (which contribute anything from a few hundreds to about £30,000 yearly, according to the college's capacity to pay) and a large one from Government through the University Grants Committee. Colleges, on the other hand, get nothing from the central body of the University and nothing directly from any Government source. They have their endowments; but the increases in their incomes from these sources have, in recent years, lagged behind those of their outgoings. It is on the colleges that the main burden of catering for the large increases in the numbers of men and women in recent years has fallen. It is good, therefore, that St. Anthony's College has been founded. It is hoped that its foundation may stimulate other benefactors to help other colleges as they go forward to their post-war tasks.

Administration and Anthropology

THE Frazer Lecture in Social Anthropology delivered before the University of Liverpool on October 23, 1946, by Dr. E. W. Smith, has now been published under the title "Plans and a People—A Dynamic Science of Men in the Service of Africa" (London: Lutterworth Press, 1948. 3*s*. 6*d*. net). Dr. Smith reviews first some developments in anthropology since 1908, stressing particularly that the study of acculturation in Africa is very largely the study of a disintegrating society and that our prime purpose in social anthropology is to study African society for its own sake, to understand how its component parts function, what changes are taking place in it and in what directions it tends to develop. Delay in publication has enabled Dr. Smith, in succeeding chapters on the new dynamic Colonial policy, advances in sociological research and the place of anthropology in planning, to take account of events since the address was given, and to assess how far the purpose of government is now not merely the maintenance of security and order but also the general social betterment of the people, and the extent to which the five-year and ten-year plans which Colonial governments have drawn up in broad outline meet his criteria for success. He points out that the recent review of the Colonial Empire, 1939–47, recognizes the importance of research into the nature of native society and its institutions, and he believes that the International African Institute has not only influenced the progress of social anthropology in Great Britain but also the British Government's decision to finance scientific research in Africa. He agrees that the value of social anthropology to the arts of politics and administration depends upon its theoretical advance, but holds that there is room for anthropological study which is at once scientific in method and directed towards the solution of practical problems. While we may differ as to ultimate values, there is much common ground, and in the spheres of nutrition, education, and the improvement of economic and social conditions the anthropologist may join his efforts with those of other scientific workers.

University and Research Section of the Library Association

The University and Research Section of the Library Association held its twelfth week-end conference during September 10–13 at the University of Birmingham. It was attended by ninety members, with Dr. Arundell Esdaile in the chair, and colleagues from Australia, Denmark, India, Sweden and Venezuela were present. The conference was welcomed to Birmingham by Dr. Wilfred Bonser, University librarian, who outlined the plans for the new University Library to be erected at Edgbaston. The chief speaker at the conference was Dr. S. R. Ranganathan, president of the Indian Library Association and formerly librarian of the University of Madras. Taking as his theme "The Challenge of the Field of Knowledge", Dr. Ranganathan pointed to the declaration made at the Royal Society Scientific Information Conference that in future librarians must be regarded as equal in standing to fellow men of science employed in research, industry and administration, and that they should receive comparable training facilities, rank and emoluments, as marking a definite advance. He showed how difficult it is for the librarian to satisfy the many needs of scholars—and especially of scientific workers—as the various fields of knowledge continually expand and overlap, particularly as seen from the point of view of library classification schemes. He demonstrated the principle and practice of the scheme known as Colon Classification, of which he is the author. During the week-end, visits were paid to the various sections of the University and other libraries at Birmingham, and the information departments of the Austin Motor Works and of Imperial Chemical Industries (Metals Division). The formal business of the annual general meeting of the Section on September 12 was followed by an account by Mr. C. C. Barnard, librarian of the London School of Hygiene and Tropical Medicine, of a visit to Hanover in May of this year as a representative of the Section at a conference of German librarians. The Medical Sub-Section held a meeting devoted to a symposium on cataloguing problems in medical publications, and also visited the Birmingham Medical Institute.

Elimination of Water from Wet Crude Oil

In a paper on the "Elimination of Water from Wet Crude Oil obtained from Bituminous Sand by the Hot Water Washing Process", by K. A. Clark and D. S. Pasternack of the Research Council of Alberta, University of Alberta, Edmonton (Reprinted from *Canadian Chemistry and Process Industries*, 1947), the authors deal with this problem from two angles, by continuous settling at atmospheric pressure and settling under pressure with evaporation; they have carried out much laboratory work towards its solution. In the first case, wet crude oil from the separation plant is mixed with a diluent (either 'topped' crude oil with S.G. 0·85 or kerosene with S.G. 0·82) and subjected to continuous settling in a suitable laboratory plant (illustrated). A ratio of diluent to crude oil of 0·7 and settling temperature 180° F. results in reduction of water content from 40 to 11·5 per cent. It is found that boiling and frothing of wet diluted crude oil before feeding to the continuous settler improves settling of water by causing coalescence of finely dispensed water, hence increase in volume of water ultimately settling out. The authors emphasize that continuous settling of diluted crude oil is not the complete answer to total elimination of water and that a subsequent operation is required to reduce the amount of finely dispersed water to limits acceptable to a refinery. Concerning mineral matter normally associated with the crude oil, it is pointed out that sand and silt readily settle out; but finely divided clay matter is carried within the finely dispersed water, possibly acting as a stabilizer, and this does not settle out, presumably because the emulsion will not break down under the conditions obtaining.

In an attempt to formulate the 'subsequent operation' above, experiments were carried out with continuous settling under pressure at an elevated temperature; but it was found that heating diluted oil up to 323° F. in this way did not cause finely dispersed water to coalesce. Further, water which does settle, does so as a gelatinous emulsion which will not flow to the discharge valve unaided by mechanical means. Hot oil and water, as is well known, make an unsatisfactory mixture at all times; but it is worse than ever with bituminous sand oil. The conclusion reached is that pressure settling is not practicable, that atmospheric settling of diluted crude oil is the first step, to be followed by evaporation in a heater and steam separator; in this way a practically dry oil can be obtained from bituminous sand, one which can then be more easily refined.

An Attempt to Detect the Magnetic Field of a White Dwarf

Dr. A. D. Thackeray has now published a description of his attempts to test Blackett's prediction on the magnetic field of massive rotating bodies (*Mon. Not. Roy. Astro. Soc.*, **107**, 5 and 6; 1947). Blackett pointed out that the ratio between the magnetic moment and the angular momentum of the earth and sun was approximately the square root of the gravitational constant divided by the velocity of light, and that this also applied to 78

Virginis (*Nature*, **159**, 658; 1947). He also dealt with the application of this formula to the white dwarfs and showed that in the case of Sirius B the equatorial field might be as much as 3×10^6 gauss. Such a field should lead to Paschen–Back splitting of the hydrogen lines of the order of 50 A., and Thackeray gives a full description of his work with the 36-inch Common reflector at the Solar Physics Observatory, Cambridge, to detect this effect. Unfortunately, there is not a very wide choice of white dwarfs suitable for the experiment, and Wolf 1346, magnitude 11·3, was selected as it was attainable with a 1-prism slitless spectrograph attached to the 36-in. reflector. It was shown that Paschen–Back splitting of $H\gamma$ is unlikely to exceed 8 A. in this star, corresponding to an upper limit of 10^6 gauss. It is emphasized that there is need for greater spectral purity in a discussion of an apparent structure in the lines, which is independent of the polarizing analyser. When 40 Erid. B became accessible in September 1947 a 2-in. $f/1$ aspherical singlet, figured and lent by Dr. C. R. Burch, was attached to the Newall 25-in. refractor for an attempt with the Wood aluminized grating spectrograph. An hour's exposure without 'Polaroid' was obtained on September 25, showing $H\gamma$ only, but exposures of one hour on September 25 and 3½ hours on September 27 through the analyser failed owing to the formation of thick haze during exposure.

Recession of Glaciers

THE Royal Geographical Society has inaugurated its new *Research Series* with a paper by Prof. H. W. Ahlmann on glaciological research on the North Atlantic coasts (London: Royal Geographical Society, 1948. 7*s*. 6*d*.). Prof. Ahlmann puts together his own and other observations on glaciers in Norway, Iceland, East Greenland and Spitsbergen. All data point the same way, to a general recession, and the same is true in many other parts of the world. The present rapid shrinkage seems to be the last stage in a recession that began about two hundred years ago when the glaciers reached their maximum extension in historical, and perhaps in post-glacial, times. This recession has resulted too in a rise of sea-level, as noted by J. Thorarinsson, F. Bergsten and others. The increasing intensity of the recession is also shown by recent changes in the extension of the Arctic pack-ice, notably in the Russian Arctic and around Spitsbergen, the northward migration of fish and certain birds and the improved cereal prospects in Iceland. The phenomenon is so widespread that it would appear to be associated with climatic fluctuations. The chief meteorological cause is held to be due to increased ablation. Radiation plays a part; but conduction is more important in the smaller icefields and at lower altitudes. On the other hand, it is stated that in the high interior of the Greenland ice there has been no increased ablation or reduced thickness of the ice. The low-pressure area of the North Atlantic apparently has moved to the north in recent years, thus favouring the flow of warm air to the Arctic.

Gresham's School Natural History Society

THE twenty-sixth report of Gresham's School Natural History Society (1948) has just been received. Membership of the Society totals well over a hundred—an eminently satisfactory number for a school. The Society is divided into Archæological, Astronomical, Botanical, Entomological, Meteorological and Ornithological Sections, all of which carry out valuable field work and present reports and papers to the Society. In the present report there are: (1) a survey of the flora of Holt and district, with an exhaustive list of plants observed; (2) an account of the surrounding insect fauna, together with lists of Lepidoptera and Orthoptera; (3) a descriptive account of the birds of the area, with a very comprehensive list and a detailed study of a fulmar colony. Extracts of papers submitted for the Holland-Martin Natural History Prizes (1944–47) are appended. The boys of Gresham's School are to be congratulated on their efficient and very valuable Natural History Society, which obviously encourages practical and field work to the utmost—a fitting basis for later work in natural history, and a great asset in their general education.

Dr. Franz Weidenreich on Human Evolution

A NUMBER of interesting papers by Dr. Franz Weidenreich are to hand. "The Trend of Human Evolution" is published in *Evolution* (1, No. 4; Dec., 1947), and "Some particulars of skull and brain of early hominids and their bearing on the problem of the relationship between Man and the Anthropoids" appears in the *American Journal of Physical Anthropology*, 5 (N.S.), No. 4 (Dec., 1947). In an article in the *American Anthropologist*, 45, No. 1 (Jan.–March, 1943), Dr. Weidenreich once again affirms his belief that Neanderthal man was the ancestor of *Homo sapiens*. The majority of physical anthropologists will probably not agree with the theories set forth in "The Neanderthal Man and the ancestors of *Homo sapiens*", but nevertheless Dr. Weidenreich can never be ignored with impunity. The last article comes from the *Transactions of the New York Academy of Sciences*, Series II, 4, No. 1 (Nov., 1941). It is a lecture on the site and technique of excavation of fossil man in Choukoutien, China. No anatomical details of the finds are given; but the student will find conveniently set out the story of the discovery and the excavation.

The Sondes Place Research Institute

THE Sondes Place Research Institute, Dorking, Surrey, of MacTaggart and Evans, Ltd., industrial consultants, is described briefly in an illustrated booklet which this firm has issued. There are fifteen laboratories, besides offices, stores, dark room, library and semi-scale building and workshops. The Analytical Laboratory and the Physical Testing and Cement Laboratories are service laboratories carrying out analysis and testing for the rest of the organisation and to some extent for clients. The Spectroscopy and Microscopy Laboratories and the dark room, as well as the X-ray Analysis Laboratory, function both as service departments and as research laboratories, but the main chemical laboratory is used exclusively for research and development. The Physical Laboratory is used mainly for physico-chemical research and for determining physical constants, while the Electronics Laboratory deals with the application of electronic methods and servo-mechanisms to industry. Work is carried out either for a fixed fee, on a time basis, or for a monthly or yearly retainer; during the past few years problems relating to abrasives, adhesives, bricks, cast iron, cement and concrete, detergents, fibre boards, gelatine and glue, gypsum, lime, linoleum substitute, mineral oils, paint, plastics, printing, synthetic organic chemicals, strip steel, etc., have been handled.

Applications of Electronics to Research and Industry

A symposium on the applications of electronics to research and industry is being arranged by the Electronics Section of the Scientific Instrument Manufacturers' Association, to be held in the Caxton Hall, Westminster, S.W.1, during November 18 and 19. The subjects for discussion are: measurement of displacement by electronic methods; frequency measurement; electronics in computing; measurement of ionizing radiation; high-vacuum gauges; the *radio sonde* and its applications; industrial applications of ultrasonics; metal detection; electronic control of batching; electronics in spectroscopy and spectrophotometry; dynamic recording of mechanical strains; and picture telegraphy. There will be an exhibition of British electronic instruments in the Caxton Hall during the period of the meeting. Particulars and tickets of admission can be obtained on application to the Secretary.

Conference on Dust in Industry

The Society of Chemical Industry is arranging a Conference on Dust in Industry, which will be held in the University of Leeds during September 28–30. The papers are being arranged in four groups, dealing with physical characteristics and estimation of dust (chairman, Prof. H. V. A. Briscoe), practical aspects of the dust problem (chairmen, Mr. Julian M. Leonard and Mr. A. V. Hussey), fire and explosion hazards (Sir Reginald Thomas), and health hazards (Prof. E. C. Dodds). Further particulars can be obtained from the General Secretary of the Society, 56 Victoria Street, London, S.W.1.

Colonial Services Appointments

The following appointments in the Colonial Services have been announced: R. B. Symington, agricultural officer, Northern Rhodesia; F. W. Champion, assistant conservator of forests, Tanganyika; P. A. Daley, assistant conservator of forests, Nigeria; D. G. Ellis, assistant conservator of forests, Nigeria; M. Gane, assistant conservator of forests, Tanganyika; G. S. MacPherson, assistant conservator of forests, Gold Coast; H. Sanders, assistant conservator of forests, Nigeria; J. R. T. Hazell, geologist, Nigeria; C. V. Cutting, analytical chemist, Tung Experimental Station, Nyasaland; D. A. Donald (agricultural officer, Fiji), senior agricultural officer, British Solomon Islands Protectorate; T. G. Strangeways (agricultural officer, Northern Rhodesia), senior agricultural officer, Hong Kong; W. O. Sunman (assistant to the Director of Agriculture, Kenya), assistant director of agriculture, Kenya; G. W. Chapman (assistant conservator of forests, Cyprus), senior assistant conservator of forests, Cyprus; N. Harris (geologist, Uganda), senior geologist, Uganda; W. G. Beaton (deputy director of veterinary services, Nigeria), director of veterinary services, Nigeria.

The Night Sky in October

New moon occurs on Oct. 2d. 19h. 42m., U.T., and full moon on Oct. 18d. 02h. 23m. The following conjunctions with the moon take place: Oct. 4d. 11h., Mercury 4° S.; Oct. 5d. 18h., Mars 1° N.; Oct. 8d. 02h., Jupiter 4° N.; Oct. 27d. 17h., Saturn 4° S.; Oct. 29d. 07h., Venus 2° S.; Oct. 31d. 00h., Mercury 0·5° N. In addition to these conjunctions with the moon, Venus is in conjunction with Regulus on Oct. 5d. 21h., Venus 0·4° S., and on Oct. 8d. 20h. Venus is in conjunction with Saturn, Venus 1·1° S. Mercury, in inferior conjunction on Oct. 20 and stationary on Oct. 28, is unfavourably placed for observation during the greater portion of the month. On Oct. 31 the planet rises 1h. 40m. before the sun and can be seen in the eastern sky. Venus rises at 2h., 2h. 40m. and 3h. 15m. at the beginning, middle and end of the month, respectively, and can be seen in the morning hours, stellar magnitude −3·6, the visible illuminated portion of disk varying between 0·64 and 0·74. Mars sets a little more than an hour after the sun during October and is not well placed for observation. Jupiter sets at 20h. 36m., 19h. 50m. and 18h. 57m. on Oct. 1, 15 and 31, respectively, and is visible in the western sky (stellar magnitude −1·6) for some time after sunset. Saturn rises at 2h. 30m. and 0h. 50m. at the beginning and end of the month, and can be seen in the morning hours, stellar magnitude 0·9. Occultations of stars brighter than magnitude 6 are as follow: Oct. 14d. 21h. 47·8m., ψ^3 Aquar. (*D*); Oct. 21d. 00h. 16·0m., 32 Taur. (*R*); Oct. 25d. 03h. 47·2m., ω Canc. (*R*); *D* and *R* refer to disappearance and reappearance, respectively, and the latitude of Greenwich is assumed. The Orionid meteors are due about October 16–24, but moonlight will partly interfere with observation of this shower.

Announcements

Prof. M. G. Evans, professor of inorganic and physical chemistry in the University of Leeds, has been appointed to the chair of physical chemistry in the University of Manchester.

Mr. W. T. Cooper, for the past five years scientific editor and head of the Publications Department of the British Coal Utilisation Research Association, has been appointed assistant secretary (editorial) of the Institute of Fuel.

The third Fleming Memorial Lecture of the Television Society will be delivered by Mr. Arthur Blok, who will give some personal recollections of Sir Ambrose Fleming. The Lecture will be given at the Royal Institution, London, W.1, on September 29, at 6.30 p.m.

It is announced that, owing to lack of funds, the International Office for Nature Protection cannot continue its work in Holland, and Dr. J. H. Westermann has resigned from the post of acting director. Following the decision of the General Council, the Bureau was recently transferred from Heerengracht 540, Amsterdam, to the Royal Natural History Museum, 31 rue Fautier, Brussels, where it will be under the supervision of Prof. V. van Straelen, vice-president of the Office.

Two courses in photoelasticity are being arranged at University College, London; one will consist of twenty-eight weekly lectures, with periods of laboratory work during the second and third terms of the session; the other, ten periods (lectures and demonstrations). Full particulars can be obtained from Col. H. T. Jessop, Photoelastic Laboratory, University College, London, W.C.1.

Erratum.—Referring to the communication entitled "A Simple Result in Quadrature" (*Nature*, August 7, p. 215), Sir K. S. Krishnan states that in the last entry of column 2 of the table, the numerator should read

$$(2\cos\tfrac{1}{2}v)^{\alpha+\beta-2}\exp\{-\tfrac{1}{2}iv(\alpha-\beta)\}.$$

Lunar Tidal Oscillations in the Ionosphere

Using the well-known radio methods of upper atmospheric exploration, Appleton and Weekes[1] showed that the E-layer of the ionosphere is subject to an unexpectedly large lunar tide. The tide was found to be semi-diurnal in character, of the order of 1 km. in amplitude, the maximum heights being reached about ¾ hr. before the lunar transits.

More recently Martyn[2] has shown that the ionospheric observations made at the equatorial Huancayo station of the U.S. Department of Terrestrial Magnetism indicate a semi-diurnal lunar tide for the F_2-layer, also of very substantial magnitude, and has shown that this lunar oscillation can be observed in both the heights and critical frequencies of that layer.

Counting the magnitude and phase of the semi-diurnal tides in the E-layer as established for the location of south-east England, we have therefore examined F_2-layer ionospheric data for the same location in order to discover whether there is any variation of phase and amplitude with height. It was also considered of interest to find out whether the lunar tide in the F_2-layer could be detected for a station as far removed from the equator as latitude 51½° N.

As the material for analysis we have used the Slough hourly values of both the F_2-layer critical frequency and also of a quantity, h_m, the height of the maximum ionization level of the F_2-layer. Values of h_m were calculated by a method we have previously described[3]. Semi-diurnal lunar oscillations have been found in the values of both f_{F_2} and h_m. The amplitude of the oscillation in the case of f_{F_2} is about 0·05 Mc./s., the maximum being reached shortly before the time of lunar transit. The amplitude of the oscillations in the case of h_m is about 2 km.; but here the maximum is attained approximately mid-way between lunar transits. Thus the lunar tidal effects in f_{F_2} and in h_m are seen to be approximately out of phase, a result not unexpected from our previous study of F_2-layer phenomena generally. What is unexpected, however, is that the lunar diurnal *height* variations for the F_2-layer are found to be entirely different in phase from those previously observed for the lower level of the E-layer, indicating an alteration of phase of lunar height oscillation with change of ionospheric level. An investigation of corresponding effects in h'_{F_2} data, which relate to an intermediate level, indicate a phase maximum at a time intermediate between those found for the E-layer and for the level of h_m for the F_2-layer.

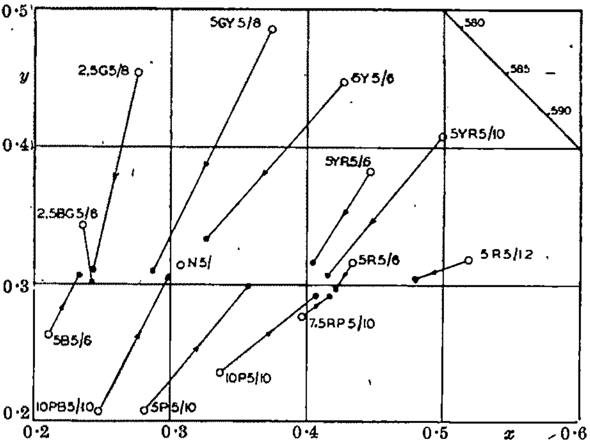
Apparent Colours of Surfaces of Small Subtense

The investigations of Hartridge[1] and others have substantiated the early conclusion of König[2] that the eye behaves as if tritanopic for coloured stimuli of small subtense, and it occurred to me that it would be of both theoretical and practical interest to determine the actual colours assumed under controlled conditions by small coloured surfaces. The first results are so striking a confirmation of König's conclusions that they are presented here as a preliminary report.

Small circular patches of a number of Munsell colours chosen from the 5-plane were presented against a black background (reflectance 2·6 per cent) singly and in random order to an observer seated at such a distance that they subtended 2 minutes of arc. The observer was provided with a chart having larger samples of all the Munsell colours in the 5-plane, systematically arranged, and a black mask with which any one colour could be isolated. The sample and the comparison chart were separately illuminated by 180 lumens m.$^{-2}$ of artificial daylight similar in colour to C.I.E. source 'C'. The observer was encouraged to be critical and to interpolate between the even values of chroma available; there was no possibility of interpolating between hues.



The figure is a portion of the C.I.E. mixture diagram showing the co-ordinates of the sample colours by open circles, and the mean location of the apparent colours at 2′ subtense by black dots. The (Munsell) neutral point is also indicated. Eight sets of observations by one observer are represented in the means.

Three main results will be noted: (1) the apparent displacements are in general directed towards or away from the short wave-length extremity of the spectrum locus ($x = 0·17$, $y = 0·01$); (2) the apparent colours lie closely about a line which if produced would cut the spectrum locus at about 491 and 630 mμ; (3) blue, green and blue-green are confused, as are also purple, red-purple, and orange; (4) yellowish-green, grey and purplish-blue are confused. The last two items, and indeed the entire picture, are in full accord with König's description of tritanopia. As an independent check of item (4), the Munsell colours lying near the straight line joining 5GY5/8 and 10PB5/10 were mounted side by side in order on the same piece of black card. At the experimental distance they appeared very nearly identical; though the extreme colours were just distinguishable. The three colours 2.5G5/8, 2.5BG5/6 and 5B5/6, similarly mounted, appeared identical.

A second observer, completely unacquainted with the Munsell colour system, obtained results similar to those shown in the figure, though with more scatter. Apparatus is being constructed to check these findings by methods less open to objection on psychophysical grounds; but of the general picture there seems no doubt.

Electronic Digital Computers

A SMALL electronic digital computing machine has been operating successfully for some weeks in the Royal Society Computing Machine Laboratory, which is at present housed in the Electrical Engineering Department of the University of Manchester. The machine is purely experimental, and is on too small a scale to be of mathematical value. It was built primarily to test the soundness of the storage principle employed and to permit experience to be gained with this type of machine before embarking on the design of a full-size machine. However, apart from its small size, the machine is, in principle, 'universal' in the sense that it can be used to solve any problem that can be reduced to a programme of elementary instructions; the programme can be changed without any mechanical or electro-mechanical circuit changes.

The essential parts of such a machine are: (1) a store for information and orders; (2) various arithmetical organs (for example, adders, multipliers); (3) a control unit[1].

The present machine contains the minimum set of facilities for a universal machine, namely: (*a*) If x is any number in the store, $-x$ can be written into a central 'accumulator' A; or x can be subtracted from what is in A. (*b*) The number A can be written in an assigned address in the store. (By means of (*a*) and (*b*) addition or direct writing into A can be programmed.) (*c*) The content of A can be tested for whether $x \geqslant 0$, or $x < 0$; if $x < 0$ the order standing next in the store is passed over. This gives the essential power of branching routines. (*d*) Control can be shifted to an assigned order in the table. (*e*) The machine can be ordered to stop.

The capacity of the store is at present only 32 'words', each of 31 binary digits, to hold instructions, data and working. Hence only simple arithmetic routines devised to test the machine can be run. Examples of problems that have been carried out are: (1) Long division by the standard process. (For $(2^{30} - 1)/31$, this took $1\frac{1}{2}$ seconds, the quotient being given to 39 significant binary figures of which the 13 least significant, to the left of the binary point, were zero, since 31 is a factor of $2^{30} - 1$.) (2) H.C.F. by the standard process. (For 314,159,265 and 271,828,183, which are co-prime, approximately 0·5 second.) (3) Factorizing an integer. For (3) the method was deliberately chosen to give a long run the result of which could be easily checked. Thus the highest proper factor of 2^{18} was found by trying in a single routine every integer from $2^{18} - 1$ downward, the necessary divisions being done not by long division, but by the primitive process of repeated subtraction of the divisor. Thus about 130,000 numbers were tested, involving some 3·5 million operations. The correct answer was obtained in a 52-minute run. The instruction table in the machine contained 17 entries.

It will, of course, be understood that it is intended to have other arithmetical facilities, as well as a much larger store, in a full-sized machine; and that even on the present machine quicker routines could have been used. At present routines are chosen with the sole object of testing the machine as thoroughly as possible.

The development of this machine has been very actively supported by the Telecommunications Research Establishment, Great Malvern.

Excitation Probability Functions of Atomic and Molecular Energy-Levels

IN the correlation of the electrical and spectroscopic properties of a glow discharge in a molecular or atomic gas, the need for a rough quantitative analysis of the kinetics of the excitation of the gas soon becomes apparent. In all but the simplest cases, no more than a rough analysis can be attempted with the present scanty experimental and theoretical knowledge of the interaction of slow electrons with atoms and molecules. It is the purpose of this communication to present an empirical form for the excitation probability functions of the atomic and molecular levels which seems to fit the few experimental curves fairly closely, and at least provides a basis for calculation where previously only generalized discussion was possible.

In principle, the excitation probability functions of atomic or molecular levels may be calculated from quantum mechanics. However, in actual fact, very few atoms and molecules have been considered[1]. In any event, serious theoretical difficulties exist in calculating the excitation probabilities for collisions with slow electrons—the interesting case from the point of view of glow discharge—where the Born approximation becomes invalid. Apart from these difficulties, it is necessary that the wave functions of the ground and excited states should be known. The wave functions of very few of the energy states of atoms and molecules have, in fact, been calculated. The quantum-mechanical method does not express the excitation probability function in a form which is readily applicable to discharge problems. Blackett[2] made an interesting semi-classical approach to the subject using the principles of conservation of energy and momentum. This, however, was limited and exploratory.

The shapes of excitation functions observed experimentally for singlet and triplet atomic levels from a singlet ground state are different[3]. The singlet excitation function rises from zero at the energy of the level concerned to a broad maximum somewhat above it, while the triplet excitation function rises from zero at the energy of the level concerned to a sharp maximum much closer to the level. The difference in shape is due to electron exchange being necessary for change of multiplicity.

An examination of the general shape of the experimental excitation functions suggests that they may be represented by:

$$s_1(V) = C(V - E_{AB})^{1/2}\exp[-L(V - E_{AB})], \quad (1)$$

where $s_1(V)$ is the excitation probability as a function of the energy V of the exciting electrons; E_{AB} is the energy separation of the ground (A) and the excited (B) states; L, an adjustable constant, controls the position and shape of the maximum ($s_{\max}$ occurs at $V = \frac{1}{2L}$); C is a scaling constant. Such a function has been fitted to the experimental curves for singlet and triplet excitation of atoms. The fit is comparable to that of the theoretical curves in cases where they have been calculated.

If (1) represents the excitation probability function for a first-kind collision between an atom and an electron, it can be applied in the relation of Klein and Rosseland[4], namely:

$$s_2(V - E_{AB}) = \frac{p_A}{p_B}\left[\frac{V}{V - E_{AB}}\right]^{1/2} s_1(V), \quad (2)$$

for the probability of the microscopically reversible case of a second-kind collision between an excited atom and an electron. p_A and p_B are the quantum weights of the states A and B respectively. From (1) and (2) we have:

$$s_2(V - E_{AB}) = C\frac{p_A}{p_B}V^{1/2}\exp[-L(V - E_{AB})]. \quad (3)$$

(1) and (3) predict the maxima of s_1 and s_2 to fall at energies which are greater by equal amounts than the energies of B and A respectively.

In the case of molecules, both experimental and theoretical knowledge is more scanty than in the case of atoms. The excitation functions of the nitrogen triplet *bands* have been investigated by numerous workers. These excitation functions are not necessarily the excitation functions of the upper levels concerned, however, as this assumes a direct excitation mechanism to these levels, and radiation as the only depopulating mechanism. As has been suggested previously[5], this assumption can by no means always be made, especially in the case of the triplet bands.

The excitations of both atomic lines and molecular band-systems are similar in that the orbital electrons in each case are the governing factor. We may therefore suppose the general shape of the excitation functions for molecular electronic levels to be the same as for atomic levels, and seek to apply the empirical function suggested above. In the molecular case, unfortunately, there are less experimental data of excitation functions (for molecular *levels*) to which the empirical equation may be fitted. Consequently, calculations must be of a more general nature than in the case of atoms. Study of the curves represented by (1) show that in cases where the experimental excitation functions are unknown, choice of $L \sim 1$ for triplet excitation functions and $L \sim 0{\cdot}1$ for singlet excitation functions enables first approximation analytical progress to be made. The postulation of a function such as (1) is necessary if any quantitative calculation is to be attempted on the excitation mechanisms in a molecular gas, when excited by electrons of an energy distribution $n(V)dV$, as exists, for example, in glow discharge. Such an analysis has been made of the excitation kinetics of nitrogen, the results of which are to be published shortly.

The choice of the suggested function has no theoretical basis. Its justification is in its fitting the experimental curves and of being of convenient analytical form. It enables some progress to be made in correlating electrical and spectroscopic data from discharge, in connexion with which this work has been done.

I should like to express my thanks to Prof. R. W. B. Pearse for valuable discussion.

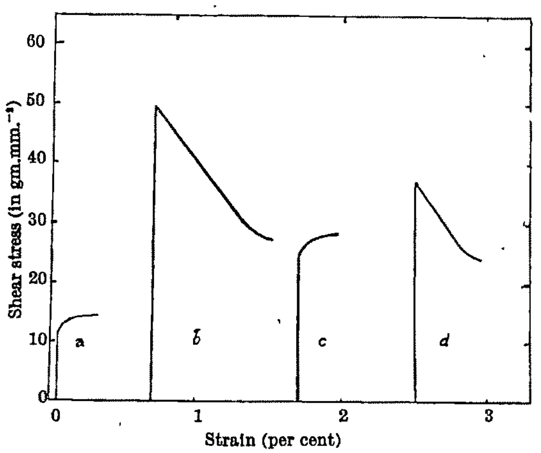
Thermal Hardening of Cadmium Crystals

BY annealing a crystal of chemically pure zinc in the temperature range 0–300° C. after a small plastic extension (~1 per cent) had been given, Orowan[1,2] found that the crystal could be made resistant to plastic deformation until a yield stress much higher than the previously determined 'normal' value was reached. The crystal would then suddenly yield and continue to extend plastically at the normal lower yield stress. On the other hand, a freshly strained crystal began to flow when retested as soon as the lower yield stress was reached. He termed the effect 'thermal hardening'. These effects remind one strongly of the yield phenomenon and strain ageing of iron, and the terms 'upper' and 'lower yield points', respectively, are suggested for the yield values belonging to the thermally hardened and freshly strained states.

Thermal hardening has been observed more recently by Smith[3] in spectroscopically pure cadmium crystals; however, whereas Orowan found the effect to be rare in zinc, Smith obtained it with every cadmium crystal he examined. We have found that cadmium crystals grown (by Andrade and Roscoe's fusion method[4]) in an atmosphere of pure argon give no sign of the effect; but marked thermal hardening could be produced consistently whenever the crystals were grown in nitrogen. It was also produced when argon contaminated by small amounts of nitrogen was used. Curve *a* shows a stress-strain curve from a crystal grown in pure argon and given a treatment designed to develop thermal hardening. The yield phenomenon, which is quite absent in this case, is clearly produced in a similarly treated crystal which has been grown in nitrogen (curve *b*); this second crystal produces the 'normal' type of curve, however, in which the yield phenomenon is absent, when it is tested in the freshly strained state (curve *c*).

Smith found that the value of the upper yield point varied markedly with λ, the angle between the axis of the applied tensile load and the glide direction, and a minimum was obtained in the range λ = 40–45°, where the upper yield point was only 5 per cent higher than the lower yield point. We have so far



Stress-strain curves of cadmium crystals. (*a*) Grown in argon; pre-strained 0·8 per cent; 40 min. at 200° C.; $\chi = 19°$, $\lambda = 30°$. (*b*) Grown in nitrogen; pre-strained 0·98 per cent; 50 min. at 200° C.; $\chi = 28°$, $\lambda = 40°$. (*c*) Immediately retested after (*b*). (*d*) Grown in nitrogen: no pre-strain; 90 min. at 200° C.; $\chi = \lambda = 56°$. (χ = angle between slip plane and tension axis.) (λ = angle between slip direction and tension axis)

failed to confirm this result; thus we have observed a difference of 70–80 per cent in the yield-points on crystals with $\lambda \sim 40°$, which is as high as can be obtained in other ranges of λ.

A difference between thermal hardening and the yield phenomenon in iron is that the characteristic yield point is produced at the first time of testing with iron, whereas with a cadmium crystal the first curve is of the type of curve *c* and the yield point type of curve is not obtained until a thermal hardening treatment has been given. The difference may be due to handling a soft crystal. To confirm this, a cadmium crystal was mounted in the testing machine and annealed *in situ* before testing. The characteristic upper yield point was developed by this treatment (curve *d*), which shows that the preliminary straining treatment is not essential and that the difference mentioned above between thermal hardening and the yielding of iron is trivial.

A subsidiary effect noticed is that, with successive annealing treatments, both the upper and lower yield points rise above their previously determined values (see table). This was found to be due to the formation of a surface film on the cadmium crystals during annealing. Roscoe[5] has shown that the presence of a thin oxide film can raise the critical shear stress of cadmium, and we have confirmed this on cadmium crystals free from nitrogen; a critical shear stress of 12 gm.mm.$^{-2}$ was obtained when the crystal surface was clean and, by a light oxidation treatment, this could be raised to 30 gm.mm.$^{-2}$.

Effect of successive annealing treatments on the yield points of a cadmium crystal ($\chi = \lambda = 56°$)

Treatment	Upper yield point, τ_1, measured as resolved shear stress in gm.mm.$^{-2}$	Lower yield point, τ_2, measured as resolved shear stress in gm.mm.$^{-2}$	$\frac{\tau_1 - \tau_2}{\tau_2} \times 100\%$
As grown	—	17·1	—
70 min. at 200° C.	33·4	20·2	65
Further 33 min. at 200° C.	32·8	20·6	59
Further 90 min. at 200° C.	41·0	21·8	88
Further 35 min. at 200° C.	42·8	23·3	83·5

A further similarity between thermal hardening and the yield phenomenon of iron is that nitrogen produces thermal hardening in cadmium, and the presence of small amounts of carbon or nitrogen in iron is associated with the yield phenomenon[6–8]. An explanation of the effects in iron, put forward recently by one of us[9], may thus be also applied to thermal hardening. It is considered that foreign atoms in solid solution migrate to dislocations, where they relieve stresses by altering locally the equilibrium lattice constants. A large force is then required to tear a dislocation from its cloud of solute atoms (upper yield point), and when a dislocation has in this way been freed it can migrate rapidly through the lattice under a smaller force (lower yield point). A freshly strained crystal contains free dislocations and shows no upper yield point; but, on annealing, the solute atoms can migrate to the free dislocations, anchoring them once more and causing the yield phenomenon to return.

We wish to thank Dr. C. L. Smith for helpful discussions, and Prof. D. Hanson and the Department of Scientific and Industrial Research for their interest and for providing facilities for this investigation.

Limiting Diffusion Currents at Wire Electrodes

THE limiting current for an electrode reaction in aqueous solution, in which diffusion of the depolarizer to the electrode surface is the rate-determining factor, is generally treated[1] by assuming there to be present adjacent to the surface a diffusion layer of fixed thickness across which a linear concentration gradient is set up. On these assumptions, the limiting current is given by the expression:

$$I = \frac{ADnFC}{\delta} \times 10^{-3}, \qquad (1)$$

where I is the limiting current (amp.), A the area of the electrode surface (cm.^{2}), D the diffusion coefficient of the depolarizing ion (cm.^{2} sec.$^{-1}$), n the number of electrons involved in the electrode reaction, F the faraday, C the bulk concentration of the depolarizer (gm. ion per litre), and δ the thickness of the diffusion layer (cm.). This expression is found to hold satisfactorily for large electrodes, and δ has a substantially constant value for different depolarizers in unstirred solutions at constant temperature. The same relation has generally been considered to hold for wire electrodes, and since such electrodes are very convenient in practice and give well-defined limiting currents, they have been much used in voltammetric work.

During an investigation of the electrolytic oxidation of potassium ferrocyanide using small vertical wire anodes of constant diameter in unstirred solutions, we found that while the ratio I/AC was satisfactorily constant over a very wide variety of conditions, as required by equation (1), its actual value of *c.* 5 × 10^{-2} (at 20° C.) was very much higher than that

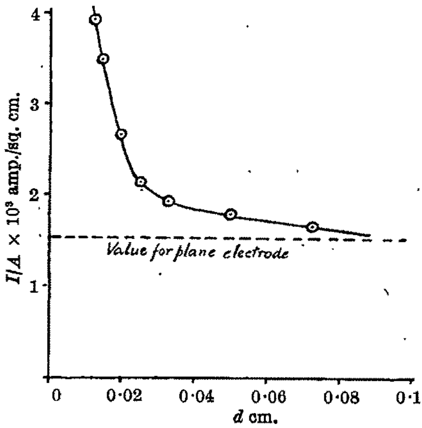

Fig. 1

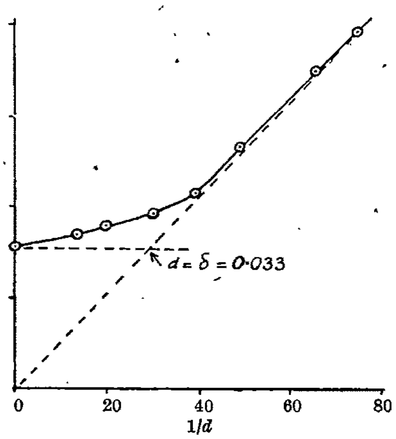

Fig. 2

of $2 \cdot 9 \times 10^{-2}$ (at 25° C.) found by Kolthoff and Laitinen[2] for the same system. In attempting to resolve this discrepancy, it was noted that these workers had used rather thicker wire electrodes than those employed in our investigation, and we have therefore made measurements with wire anodes of different diameters.

We have now found that the ratio I/AC increases rapidly with decreasing diameter when the wire becomes sufficiently thin. Some typical results are shown in Fig. 1 in which the limiting current density in amp./sq. cm. for the anodic oxidation of $0 \cdot 05M$ potassium ferrocyanide in phosphate buffer at 20° C. is plotted against the diameter d of the wire used. It may be noted that with the thickest wire used of diameter 0·0725 cm., the limiting current density is only slightly higher than that found for a plane electrode, but with decreasing diameter it increases, and below a diameter of 0·04 cm. the increase is very rapid indeed. In Fig. 2 the limiting current density is plotted against the reciprocal of the diameter, and it is seen that for very thin wires it becomes inversely proportional to the diameter; and it appears that:

$$I = \frac{ADnFC}{d} \times 10^{-3}. \qquad (2)$$

The intersection of the dotted lines representing the limiting cases (1) and (2) gives a value of δ of 0·033 cm. Other determinations of δ involve a knowledge of the diffusion coefficient of the depolarizing ion, about which there is usually considerable uncertainty. Early work[1] suggested a value of δ of about 0·05 cm., but Kolthoff and Laitinen[2] from a study of a number of reactions arrived at a value of 0·025 cm. Re-examination of their results, however, shows that their limiting current densities would be about 1·2 times the values for plane electrodes, owing to the diameter effect now reported; and if allowance is made for this, their results give a value of δ of 0·03 cm. (at 25° C.), which is in close agreement with that of 0·033 cm. (at 20° C.) obtained above.

The effect now reported appears to be a general one independent of the nature and concentration of the depolarizer used. In general, it is obvious that when the diameter of the wire approaches the thickness of the diffusion layer, equation (1) must fail, and indeed the diffusion must be of a cylindrical rather than a linear type. We have attempted to account for the experimental results by using the general equation for cylindrical diffusion (which does not of itself lead to any stationary state such as is experimentally observed) and inserting arbitrary boundary conditions; but these attempts have not led to any practically useful result. Empirically, a close fit to the experimental points can be obtained if equation (1) is formally retained and the diameter of the wire d replaced by $\sqrt{d^2 + \delta^2}$ in calculating the electrode area, and this may have some practical value for calculation purposes, although its physical significance is obscure.

The present results have two practical implications. First, in comparing results of limiting current measurements at wire electrodes, as is often done, the wires used must be fairly thick, or of the same diameter, or a correction factor must be introduced. Secondly, in designing electrodes to obtain very high limiting currents, as, for example, the platinum gauze electrodes used in electro-analysis, there is an obvious advantage in using the thinnest possible wire consistent with mechanical strength; our measurements show that the limiting current per unit length of wire becomes independent of diameter for very thin wires, and hence some saving of metal may be achieved by this procedure.

We are indebted to Mr. T. B. Grimley for much helpful discussion.

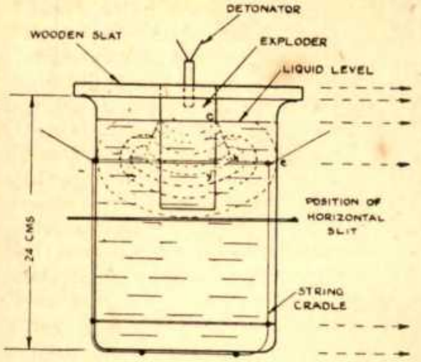
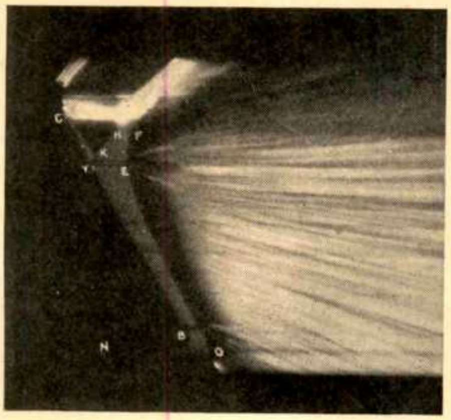
Detonation in Liquid Explosives

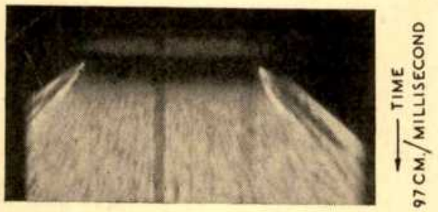
DURING the War a general investigation was commenced at the Road Research Laboratory, on the initiative of Dr. A. H. Davis, into the process of detonation in explosives, the programme including a photographic study of the detonation waves in transparent liquid explosives—the sensitivity of some of which can be varied by adjusting the constitution—and their relation to primers of different types and shapes. In the work, use was made of a new high-speed mirror camera to photograph the progress of the luminous detonation front inside transparent liquid explosives. A unique feature of the camera was the employment of two independent lens assemblies, each consisting of a telephoto field component focusing on to a spectrographic slit. The slits themselves were focused, via a four-sided rotating mirror, on to a photographic film located in cylindrical guides. The fields of the two slits were arranged to intersect at right angles in the object plane, approximately 30 ft. from the camera. Further, by means of a suitable arrangement of plane mirrors between the rear lenses and the film, images from the two slits were arranged to record on different areas





→ TIME : 97 CM/MILLISECOND

RECORD FROM VERTICAL SLIT



RECORD FOR HORIZONTAL SLIT

Crown Copyright Reserved

[*Reproduced with the permission of the Controller of H.M. Stationery Office*

of the same film. Use was made in this connexion of adjacent sides of the mirror block. In this manner it was possible to record simultaneously in two directions at right angles. The maximum recording speed was approximately 100 cm. per sec., with a time resolution of 1 microsecond.

A record obtained during the detonation of a 14-lb. charge of the transparent liquid explosive diglycol dinitrate, using a 12-oz. cylindrical tetryl primer, is reproduced herewith. The vertical slit was focused on the axis of the glass beaker used to contain the explosive, while the horizontal slit covered a section slightly below the bottom of the primer. To facilitate interpretation, the sketch of the charge is reproduced to the same linear scale as the records.

Referring to the record from the vertical slit, the flash from the detonator occurs first in time, followed by extensive luminosity from the section of the primer between the underside of the primer support and the level of the liquid. The flame front from this zone, travelling towards the camera, is later deflected upwards by the glass wall of the beaker. The boundary *CYB* on the record indicates the passage of the detonation front, first down the side of the primer and afterwards, with a slight decrease in velocity, down the axis of the beaker. During its passage from *c* to *y* along the primer, the detonation front has spread, to a limited extent only, into the liquid explosive, as sketched on the diagram. This encroachment is indicated by the boundary *CK* on the record.

On a circle concentric with the charge axis, and passing through the point *k*, a new detonation process has originated in the liquid. This has combined with the original wave to form a front of the shape sketched. The upward movement of this front is recorded as the boundary *KH*. When the detonation wave reaches the glass at *e*, luminosity ceases for a few microseconds, before the commencement of burning in air. This corresponds to point *E* on the record. As the expanding front shatters the glass, the boundary *FEG* is developed. From a mathematical analysis of this boundary the shape of the detonation wave can be derived. (The tail *NB* is due partly to reflexion from the convex base of the beaker, and partly to refraction at the curve in which the wall of the beaker meets the base.)

The horizontal slit records nothing until the detonation front in the liquid crosses its field. The curved boundary again gives a key to the shape of the wave, but in this case a correction must be made for refraction in the undetonated liquid. The record as it stands gives the impression that the detonation front has been temporarily contained by the glass !

Using this technique the critical primer/charge diameter ratio necessary to give complete detonation was investigated, and the effect of shaping the primer examined. The horizontal slit was found to be invaluable in the elucidation of the more complex detonation processes associated with shaped primers.

Some of the records obtained suggested that diglycol dinitrate has one or more low orders of detonation of the kind referred to recently by Jones and Mitchell[1]. Unfortunately, the luminosity associated with them was insufficient to record on the fastest film available, and the detonation process had to be reconstructed from the envelope of the after-burning, which was generally sufficiently luminous to record.

This communication is published by permission of the Director of Road Research and of the Chief Scientist, Ministry of Supply, for whom the work was undertaken.

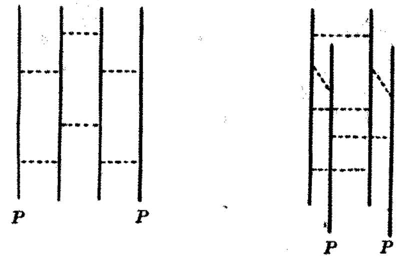
Some Peptides from Insulin

By oxidation with performic acid, the insulin molecule can be split into its separate polypeptide chains[1]. It has now been possible to prepare two fractions from the oxidized insulin : fraction *A* contains only glycine terminal residues and no arginine, histidine, lysine, phenylalanine or threonine ; fraction *B* contains 97 per cent phenylalanine terminal residues and all the amino-acids that are present in insulin. The yield of fraction *A* is more than 25 per cent of the original insulin, indicating that it represents more than one of the peptide chains of the insulin. The yield of fraction *B* is rather less.

The sulphur contents of the two fractions were kindly determined by Mr. M. W. Rees, who found



that fraction *A* contains four cysteic acid residues per molecule of molecular weight 2,900, and fraction *B* contains two per molecule of molecular weight 4,100. From these results it is possible to formulate a number of possible structures for the insulin sub-molecule. Thus, if we assume that it can be regarded as four parallel peptide chains, then only two structures are possible, as shown in the accompanying diagram, where the full lines represent the peptide chains and the broken lines the —S—S— bridges. The chains marked *G* have glycine terminal residues and those marked *P* phenylalanine terminal residues. It is assumed that the two glycyl chains have equal cysteic acid contents, which is probable from their similar properties. Other structures are possible if the chains cannot be regarded as parallel.

In order to carry further the investigation of the structure of these peptides, the products of the partial hydrolysis of their 2 : 4-dinitrophenyl-derivatives were studied. Using this method, it is possible to separate from a complex partial hydrolysate a relatively simple mixture of dinitrophenyl-peptides originating from the terminal peptides of the molecule. The isolation of a number of such peptides from an enzymic digest of insulin has already been reported by Woolley[2]. In the present work, acid hydrolysis has been used and the dinitrophenyl-peptides fractionated by partition chromatography on silica gel. The order of the amino-acids in them was determined by subsequent partial hydrolysis.

In a preliminary experiment with horse globin, the following peptides were isolated in a crystalline form and their structure determined: *H*1, 2 : 4-dinitrophenyl-valyl-leucine; *H*2, 2 : 4-dinitrophenyl-valyl-glutamyl-leucine; *H*3, the amide of *H*2.

This demonstrates that the six open peptide chains of horse globin[3] are not identical but consist of at least two different types, one with the terminal peptide valyl-leucine and one with the terminal peptide valyl-glutaminyl-leucine.

The method was then applied to the above fractions of oxidized insulin. From a partial hydrolysate of the dinitrophenyl-derivative of fraction *A* the following peptides were separated: *A*1, 2 : 4-dinitrophenyl-glycyl-isoleucine; *A*2, 2 : 4-dinitrophenyl-glycyl-isoleucyl-valine; *A*3, 2 : 4-dinitrophenyl-glycyl-isoleucyl-valyl-glutamic acid; *A*4, the peptide containing glutamic acid, leucine, serine and O-2 : 4-dinitrophenyl-tyrosine, which has been reported by Woolley[2]. Its structure has not yet been determined.

Fraction *A* thus consists of at least two separate chains with different terminal peptides. It is interesting to note that these chains, though not identical, are very similar in that they have no basic amino-acids, threonine or phenylalanine, are not easily separated from one another and have the same molecular weight and electrophoretic mobility.

Using fraction *B* the following peptides were detected: *B*1, 2 : 4-dinitrophenyl-phenylalanyl-valine; *B*2, 2 : 4-dinitrophenyl-phenylalanyl-valyl-aspartic acid; *B*3, 2 : 4-dinitrophenyl-phenylalanyl-valyl-aspartyl-glutamic acid; *B*4, ε-2 : 4-dinitrophenyl-lysyl-alanine; *B*5, threonyl-(ε-2 : 4-dinitrophenyl)-lysyl-alanine.

No evidence has yet been obtained of a second chain in this fraction.

The method of determining the structure of these peptides can be illustrated by considering the peptide *A*3. Using quantitative paper chromatography[4], it was shown that there was one molecule of isoleucine, valine and glutamic acid per molecule of 2 : 4-dinitrophenyl-glycine. While no great accuracy is claimed for this method as used here, it is sufficient to indicate without any doubt the number of residues present. On further partial hydrolysis of peptide *A*3, the peptides *A*1 and *A*2 and 2 : 4-dinitrophenyl-glycine were produced. From the composition of these peptides the order of the amino-acids could then be deduced, and it was confirmed by the identification of isoleucyl-valine in partial hydrolysate of peptide *A*2, by the method of Consden, Gordon and Martin[5].

In addition to peptide *A*4, Woolley has isolated from insulin a number of 2 : 4-dinitrophenyl-glycyl peptides in which threonine occurred not far from the terminal residue. We have not yet found evidence of these peptides in the present work in any of the main fractions of oxidized insulin; but it may be that they are not extracted under the procedure employed. It is possible, therefore, that there may be at least three different glycyl chains in insulin, though it is difficult to reconcile this with the present picture of the structure of insulin.

"17-Ketosteroid II" Isolated from Urine; its Reaction with Hydrochloric Acid

In an earlier communication[1] we announced the isolation of a new 17-ketosteroid in the urine of a girl with adenoma of the adrenal cortex. This compound, which we designated "17-ketosteroid II", is converted in presence of HCl into a mixture of $C_{19}H_{27}OCl$ and dehydro-*iso*-androsterone. We have now studied this reaction in more detail.

In the first place we were able to prove that the compound $C_{19}H_{27}OCl$ is identical with the 3-chloro-Δ^5-androstenone-17 isolated by Butenandt and Dannenbaum[2] from human male urine. This compound can be synthesized by the method of Wallis and Fernholz[3] by the action of phosphorus pentachloride on dehydro-*iso*-androsterone. We purified the product thus obtained by means of chromatographic analysis. The melting point was 153·5–155·5° C. (corr.).

We then added 5 per cent aqueous hydrochloric acid to a solution of pure 17-ketosteroid II in ethanol; under these conditions the latter reacts immediately even at room temperature. The reaction mixture consists of about 80 per cent of $C_{19}H_{27}OCl$

with 20 per cent of dehydro-*iso*-androsterone. The chloroketone prepared from 17-ketosteroid II had m.p. 153·5–155·5° C. The mixed melting point with synthetic 3-chloro-Δ^5-androstenone-17 showed no depression.

In view of the great readiness with which 17-ketosteroid II reacts with hydrochloric acid to form 3-chloro-Δ^5-androstenone-17 (unlike dehydro-*iso*-androsterone), we assume that the 3-chloro-Δ^5-androstenone-17 found in urine has been formed from 17-ketosteroid II and *not* from dehydro-*iso*-androsterone (though 17-ketosteroid II occurs in normal urine in small quantities only). Although everywhere in the literature it is assumed that the chloroketone is formed from dehydro-*iso*-androsterone, Butenandt and co-workers[2] in their original publication did actually point to the possibility of a different precursor.

When 17-ketosteroid II is subjected to the action of hydrochloric acid at 100° C., the product is chiefly dehydro-*iso*-androsterone. When hydrochloric acid is allowed to act for 10 min. on 3-chloro-Δ^5-androstenone-17 (at 100°) the reaction mixture contains about 65 per cent of dehydro-*iso*-androsterone, the remainder being unchanged 3-chloro-Δ^5-androstenone-17. The identity of the dehydro-*iso*-androsterone was proved by means of the mixed melting point with an authentic sample of dehydro-*iso*-androsterone, 140–141° C. (corr.), and the mixed melting point of the corresponding acetates, 170–171° C. (corr.).

These facts lead us to the conclusion that the dehydro-*iso*-androsterone found in relatively large amounts in the urine of patients with carcinoma of the adrenal cortex must be regarded, to some extent at any rate, as an artefact produced by the action of hydrochloric acid on 17-ketosteroid II at the boiling point.

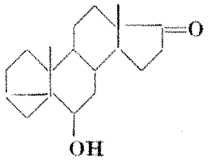
It also appears that the amount of dehydro-*iso*-androsterone thus formed is dependent on the duration of heating with hydrochloric acid. Boiling for 10 min. converts about 65 per cent of the 17-ketosteroid II to dehydro-*iso*-androsterone (see above). If, however, the urine is extracted with an organic solvent before hydrolysis, the 17-ketosteroid II present in the unconjugated form passes into the organic solvent. The result of such a method of extraction is that the amount of dehydro-*iso*-androsterone in the extract is much smaller than when the urine is boiled immediately with acid.

We think it worth while to direct attention to this in connexion with the estimation of dehydro-*iso*-androsterone in urine extracts for clinical purposes.

We have not yet succeeded in ascertaining whether 17-ketosteroid II can also exist in conjugated form in urine. In our previous communication[1] we stated that an acetate of this compound had been prepared (m.p. 109–111° C. (corr.)). Thus it contains an alcoholic hydroxyl group, so that it is by no means impossible that it may also be present in the esterified form in urine. The usual methods of hydrolysis will, however, convert these esters into dehydro-*iso*-androsterone.

Drs. Barton and Klyne (see following letter) kindly sent us a specimen of synthetic *i*-androsten-6-ol-17-one which proved to be identical with our 17-ketosteroid II; an identity that has already been considered in our previous paper. (We are glad to mention here that Dr. Beyerman, working at this Laboratory, suggested this identity for the first time, and we acknowledge with thanks this useful hint.) The identity of the compounds is established by mixed melting points and by identical adsorptive properties in chromatography.

The structure of 17-ketosteroid II is thus completely elucidated.



i-androstenolone

A grant was received for this study from Organon, Ltd., Oss.

Identification of "17-Ketosteroid II" as *i*-Androsten-6-ol-17-one

Dingemanse, Huis in 't Veld and Hartogh-Katz[1] recently described the isolation from human urine of a compound, "17-ketosteroid II", which they suggested was an androsten-3(α)-ol-17-one. Many of the reactions reported for this substance indicated that it might be *i*-androsten-6-ol-17-one, which has already been obtained by Butenandt and Suranyi[2] from the *p*-toluenesulphonate of dehydro-*iso*-androsterone. We have repeated the preparation of Butenandt and Suranyi, and have confirmed the properties recorded for this substance and for the corresponding diketone obtained on oxidation. The properties of "17-ketosteroid II" and *i*-androstenolone are compared in the accompanying table.

	17-Ketosteroid II	*i*-Androsten-6-ol-17-one
Melting point	140·5–141°	139–140°
$[\alpha]_D$ in alc.	+121°	+122°
Melting point of diketone obtained by oxidation	185°	184–185°

Our *i*-androstenolone showed no depression in melting point on admixture with "17-ketosteroid II" by Dr. Dingemanse, to whom we are most grateful for carrying out this comparison. The agreement in physical and chemical properties between the two compounds, together with this mixed melting point determination, proves that "17-ketosteroid II" and *i*-androsten-6-ol-17-one are identical.

The chloroketone, $C_{19}H_{27}OCl$, m.p. 151–152°, obtained by the Dutch workers by the action of hydrochloric acid on "17-ketosteroid II", must be 3(β)-chloroandrost-5-en-17-one, m.p. 155–157°, first isolated from urinary extracts by Butenandt and Dannenbaum[3].

So far as we are aware, this is the first report of the isolation of an *i*-steroid from urine or from any other natural source. Rosenheim[4] suggested that an *i*-steroid might be the precursor of the chloro-compound mentioned above. That *i*-steroids have not been detected previously in urine is doubtless due to the fact that the usual method of working up urine for its steroidal content (acid hydrolysis) must lead to the rearrangement of much or all of the *i*-steroids contained therein.

Deodorization of Shark Liver Oil

SHARK liver oil, which is one of the cheapest and most plentiful sources of vitamin A in Nature, has a highly disagreeable odour which is very much more pronounced than that of cod liver oil. On account of its unpalatability it does not easily find favour with the consumers. The deodorization of the oil has to be effected in such a manner that the highly susceptible vitamin A is retained intact. Among the various methods that we have tried to achieve this result are: (i) steam-'distillation' of the oil under normal and reduced pressure in which the malodorous substances pass over with the steam; (ii) agitation of the oil with fermenting milk and toddy; and (iii) selective hydrogenation of the oil in the presence of a nickel catalyst.

Steam-treated oils are fairly free from odour when freshly prepared, but revert in the course of a few days to their original character. Oils, deodorized by agitation with fermenting milk or toddy, have been found to remain bland for several months. The accompanying data with regard to the chemical constants, potency and stability of oils deodorized with fermenting milk and toddy as compared with those of the original oil show that very little change in these vital characteristics is involved in the process.

Chemical characteristics

	Milk-deodorized		Toddy-deodorized	
	Control	Treated	Control	Treated
Acid value	0·2	0·3	2·0	2·2
Saponification value	188	199	191	191
Iodine value	128	128	109	108

Vitamin A potency in international units per gram

Species of shark	Milk-deodorized		Toddy-deodorized	
	Control	Treated	Control	Treated
Stegostoma tigrinum	1,200	1,100	3,800	3,800
Pristis cuspidatus	5,900	5,900		
Hammerhead	37,000	36,900		
Bulk sample	11,200	11,100	9,600	9,600

Stability of the oil

Time, days	Peroxide value			
	Milk-deodorized		Toddy-deodorized	
	Control	Treated	Control	Treated
0	9·4	9·8	6·0	4·5
1	17·8	15·9		
2			21·4	23·6

6	94·5	96·8	103·9	110·1
8	198·0	210·4		

Brocklesby[1] has indicated that hydrogenation of fish liver oils under carefully controlled conditions would eliminate the malodorous factors while the vitamin A itself may be kept unimpaired. Working with 0·1, 0·25, and 0·4 per cent concentrations of nickel catalysts prepared by the method of Adkins, Covert and Connor[2], we have obtained results which are quite promising. While 0·1 per cent of catalyst is not sufficient to effect complete deodorization (organoleptic test) within a temperature range of 100–180° C., 0·25 per cent of the catalyst effected fairly complete deodorization of the oil at 120° C. within 30–45 min. The percentage loss of vitamin A by this process is about 7, and stability studies have shown that the keeping quality of the oil has improved very considerably. 0·4 per cent of the catalyst caused increased destruction of the vitamin.

The accompanying table, giving results obtained with 0·25 per cent nickel catalyst at temperatures between 100° and 180° C. and reaction periods from 30 to 180 min., shows that the loss of vitamin increases progressively with increase in temperature and time of exposure.

	Time (min.)	Temperature (°C.)				
		100	120	140	160	180

Activities of Associating Solutes

THERE are comparatively few cases of binary mixtures in which the activity or fugacity of one component has been interpreted in terms of molecular properties. Well-known instances of such treatments are the Debye–Hückel theory of electrolytes and Hildebrand's theory of regular solutions. We have examined the case of a binary mixture where interaction between the two components is negligible, but where one of the components (the solute) has a tendency to form multiplets of any degree of complexity by means of association. Since interaction is assumed to be negligible, the non-ideality of the solute is attributable entirely to association, and each multiplet species (including the monomer) may be supposed to constitute an ideal sub-system. We propose to call mixtures of this type 'perfect associating mixtures'.

Since the solvent plays an entirely inactive part, a special case of this type is that of a gas, the ultimate molecules of which can associate to give multiplets. The second component (the solvent) is here replaced by the free space between the gaseous molecules. For sufficiently high temperatures and low pressures, each multiplet sub-species may be regarded as forming an ideal gas.

Examples of this type of system are certain solutions of polar solutes in non-polar solvents, and gaseous systems such as sulphur or iodine vapour at high temperatures.

The 'solute' will be considered as an equilibrium mixture of single molecules, doublets, triplets, etc. The total molarity (in terms of single molecules) of the solute will be denoted by n_s and the molarity of the various individual species (in terms of the appropriate multiplet molecules) by x_r. Here $r = 1$ for singlets, $r = 2$ for doublets, etc. If μ_r is the chemical potential of the r^{th} species, then

$$\mu_r = \mu_r^0 + RT \ln x_r. \qquad (1)$$

All species exist in equilibrium with one another, hence

$$r\mu_1 = \mu_r. \qquad (2)$$

If a definite volume of solution is considered (say 1 litre), x_r may be taken as the masses of the various species (expressed in moles). Hence if G_s is the Gibbs free energy of the solute as a whole

$$G_s = \sum_{r=1}^{\infty} x_r\mu_r = \mu_1 \sum_{r=1}^{\infty} rx_r. \qquad (3)$$

If μ_s is the chemical potential of the solute species as a whole

$$(\partial G_s/\partial n_s)_{T,P,n_l} = \mu_s, \qquad (4)$$

where n_l is the mass of the solvent in one litre of solution. For n_s, we can write

$$n_s = \sum_{r=1}^{\infty} rx_r. \qquad (5)$$

Equation (4) and subsequent equations derived from it would hold for solutions sufficiently dilute for n_l to be effectively constant, that is, for the volume of the solution to be approximately equal to the volume of the solvent. Thus, from equations (3), (4) and (5),

$$\mu_s = (\partial G_s/\partial \sum_r rx_r)_{T,P,n_l} = \mu_1. \qquad (6)$$

Writing the last equation fully,

$$\mu_s^0 + RT \ln a_s = \mu_1^0 + RT \ln x_1, \qquad (7)$$

where a_s is the activity (or the fugacity) of the 'solute' species as a whole. Since at infinite dilution n_s tends to x_1 and also to a_s, the standard chemical potentials μ_s^0 and μ_1^0 must be identical and hence

$$x_1 = a_s. \qquad (8)$$

For such mixtures, therefore, the activity of the solute (in molarity units) is identical with the molarity of the singlet species. For the conditions when this is valid (that is, volume of solution approximately equals volume of solvent), it is easily deduced that it is also true that the activity of the solute (in molality units) equals the molality of the singlet species. For the corresponding case for associating gases a similar treatment yields the result that the fugacity of the gas equals the partial pressure of the singlet species.

The application of this new relationship to certain gaseous and liquid systems will be discussed at greater length elsewhere.

Autoradiography of the Thyroid Gland

AUTORADIOGRAPHY of the thyroid gland has been carried out by various methods: (1) mounting sections of tissues containing radioactive iodine on glass slides, applying these slides with pressure against the emulsion of a photographic plate[1]; (2) melting photographic emulsion and pouring it over a section[2]; (3) mounting the sections directly on the photographic emulsion[3]; and (4) a modification of (2), by removing from its base Ilford half-tone thin film, dry-stripping emulsion and mounting it on top of the slide-bearing sections[4].

The first method, although the stained slide and the developed photographic plate may be examined in conjunction, does not permit accurate localization. In the second method a heavy blackening of the emulsion may obscure the section, even though stained. Pelc[4] was unable to stain the section through the emulsion in the fourth method. The third is simple to use, and the section may be stained with ease, and precise histological localization of the blackening of the emulsion obtained. It is well suited for serial sections used in the present work.

In the present experiment, 25 micro-curies of radioactive iodine (I^{131}) was injected in the form of sodium iodide intraperitoneally into a normal adult male mouse. After two hours, the animal was killed with chloroform. The thyroid lobes were removed and fixed in aqueous formalin. Water-soluble iodine compounds are dissolved by aqueous fixatives and may either be removed from the tissue or translated. To obviate this, Pelc[4] fixed thyroid tissue in alcohol. However, it has been shown[5] that autoradiographs obtained by fixing thyroid tissue in aqueous fixatives do not differ from those obtained by freeze-drying. This indicates[6] that iodine is probably rapidly bound to protein in the gland and ceases to become diffusable. Aqueous fixatives are therefore admissible for thyroid autoradiographs.

Following fixation, the thyroid lobes were embedded in wax in the usual way, and serial sections of the whole gland were cut at a thickness of 7 μ. The ribbons bearing the sections were floated on warm water in a dark room and mounted directly on to the emulsion of Ilford thin-film high-resolution plates (4½ cm. × 6 cm.). All sections were mounted in series and dried overnight. Then the wax was dissolved off (paraffin wax absorbs some of the radiation). The plates were re-dried and kept in a light-tight box for six days, then developed by usual methods. The sections remained in place and were later stained with neutral red. (Hæmatoxylin and eosin) tends to obscure the blackened emulsion. Localization of radioactive iodine in the colloid of the follicles was clearly demonstrated by this method. It is known[6] that within half an hour of administration radioactive iodine has begun to accumulate in the thyroid,

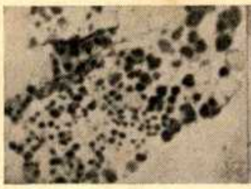

Fig. 1

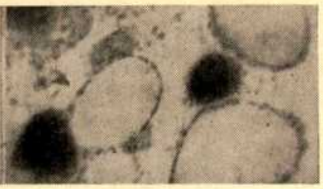

Fig. 2

Fig. 1. Low-power view (× 40) of autoradiograph of mouse thyroid. Small and medium-sized follicles are blackened; larger follicles are not

Fig. 2. High-power view (× 270) of part of autoradiograph of mouse thyroid. Two large follicles can be seen with practically no blackening of the colloid. In the top right-hand corner can be seen a further large follicle in which the follicular cells are taller than in the other large follicles in the section. The colloid has blackened slightly more than in the others. Two small follicles can be seen which have given an intense blackening

and in the present work (two hours after injection) most of the follicles had shown some signs of concentrating the iodine.

The smallest follicles appeared to have concentrated the radioactive iodine more rapidly than the larger follicles. (Hamilton[7] made a similar observation on the thyroids of two hypothyroid children.) In some very large follicles no blackening in the region of the colloid had occurred. In these the process of concentrating iodine was probably at a very low level or had ceased.

It was found that no part of the thyroid was more active than any other part in concentrating the radioactive iodine. Follicles of different sizes were scattered indiscriminately through different parts of the gland. All the small follicles with cuboidal or near-cuboidal cells had radioiodine in their colloid, and all the large ones showed varying amounts according to the degree of flattening of the epithelium. In some large follicles with moderately flattened cells—although the colloid showed no reaction—there was a rim of blackened emulsion surrounding the colloid and coinciding with the epithelium. It is of interest that blood vessels in the preparations, which must have been carrying radioactive iodine, showed no signs of having blackened the emulsion, presumably because the former is present in too low a concentration. Leblond[8] has shown that, 15 hr. after administration, radioactive iodine is present in greater amounts in acidophilic than basophilic thyroid follicles (Mallory's trichrome stain); he believes the difference is due not to the differing powers of storing radioiodine but to variation in time of retention. The present experiment (2 hr. after administration) suggests that iodine is still being absorbed and that the follicles store it at various rates, and that the more flattened the epithelium the slower the rate of storage (a not unexpected finding). The staining method used did not permit a satisfactory differentiation between acidophilic and basophilic follicles.

Effect of Phosphorus on the Hydrolysis and Absorption of Sucrose by Plant Cells

SOME years ago I demonstrated[1] that excised barley leaves from phosphorus-deficient plants showed considerably increased respiration intensities if their cut ends were immersed in neutral sodium phosphate solution instead of water. Feeding similar leaves with sucrose solution also increased the respiration-rates; but the increase was much smaller than when phosphorus was administered. The sucrose effect was less apparent when phosphorus deficiency was more acute. Still higher rates of respiration were obtained if the phosphorus-starved leaves were supplied with both sucrose and phosphate together.

Later, I showed[2,3] that when slices from storage organs are floated in sucrose solution, the latter is never absorbed by the plant tissues as such: but it is always first inverted in the medium and the products of inversion are afterwards absorbed. I have recently noticed the same phenomenon when the cut ends of plant leaves are dipped in sucrose solution, the sucrose being hydrolysed before its absorption. Feeding experiments on normal and phosphorus-starved barley plants are now in progress, and the results indicate that when excised phosphorus-starved leaves are dipped in sucrose solution, the rate of sucrose inversion in the medium and also the rate of uptake of the hydrolysis products are remarkably reduced. Feeding with neutral phosphate and sucrose together restores the normal hydrolytic and absorptive capacities to these plants.

This is interesting because it shows that in the early respiration experiments, the sucrose of the culture medium never entered the cells as such; and sucrose could not be synthesized inside the phosphorus-deficient cells because of the lack of phosphorus[4,5,6,7]. It is also evident that the respiratory substrate may be directly produced from sucrose hydrolysis[8,9,10]; but the latter process is extremely affected by phosphorus, being very much reduced under conditions of phosphorus starvation. In this connexion, it may be mentioned that Lyon[11] and Richards[12] advocated the view that phosphate is normally involved in the respiratory breakdown of sugar in plant leaves.

Crystallization of Whale Myoglobin

ALTHOUGH the spectroscopic differences between blood and muscle hæmoglobin were first observed by Mörner[1] in 1897, it was not until 1932 that Theorell[2] succeeded in crystallizing myoglobin from horse-heart muscle.

The myoglobins from several species of animals have since been prepared by various workers[3,4,5,6], and recently Theorell[7] described the preparation of crystalline human myoglobin from heart muscle and from the urine of cases of myoglobinuria.

Whale meat is of a very dark colour, and since it is often available, it was of interest to establish whether it is suitable for large-scale preparations of crystalline myoglobin. Two methods of preparation are described below, and in each case good yields of crystalline myoglobin are obtained. For the production of larger crystals suitable for X-ray crystallography, the final crystallization must be carried out in phosphate solutions.

(*a*) *Crystallization of CO-myoglobin* (J. K.). The whale meat (about 4 kgm.) was roughly dissected to remove any neurovascular bundles while it was still frozen solid, cut into small cubes which were inspected for any remaining blood vessels and minced. The mince was extracted with an equal weight of water overnight in a cool place. The fluids obtained first by draining and then by pressing the mince in a hydraulic press were sometimes found to be very greasy and had to be centrifuged to remove the fat as a solid layer from the surface of the fluid. The dark red myoglobin solution was neutralized with 10 per cent sodium hydroxide to *p*H 7·3, and the bulky precipitate formed was removed by filtration through paper pulp. (For all subsequent filtrations a Buchner funnel with hardened paper was used.) The filtrate was brought up to 50 per cent and then to 70 per cent saturation with ammonium sulphate, keeping the *p*H at 7·3, and the resulting precipitates were in each case filtered off and discarded. The pigment which had by now oxidized to metmyoglobin was converted to CO-myoglobin (using a minimal amount of $Na_2S_2O_4$ as reducing agent) as this compound is more resistant to denaturation than metmyoglobin. The pigment was examined spectroscopically after each of the following manipulations, and carbon monoxide was passed through the solution when necessary. The myoglobin was next brought up to 80 per cent saturation with ammonium sulphate, rapidly filtered and the precipitate was discarded. The filtrate was dialysed against neutralized saturated ammonium sulphate until the myoglobin was completely precipitated, when it was filtered off, dissolved in distilled water and reprecipitated by dialysis.

The myoglobin was then fractionated by dialysis against neutralized ammonium sulphate at 60, 70 and 75 per cent saturation respectively, all precipitates being discarded. The filtered CO-myoglobin was finally dialysed against neutralized 80 per cent saturated ammonium sulphate until it was just faintly turbid, when it was transferred to a closed glass vessel and placed in the cold to crystallize. Whale CO-myoglobin prepared by this method forms needle- or lens-shaped crystals arranged singly, in sheaves, or in rosettes. Flat plate-like crystals with parallel sides have also been observed in the course of one preparation.

(*b*) *Preparation of Metmyoglobin crystals* (K. S.). This method was based on the known differences of solubility between the hæmoglobin and myoglobin of any particular species of animal in concentrated phosphate buffer, as described by Morgan[8] and Theorell[7].

A mixture of 491 gm. $NaH_2PO_4.2H_2O$ and 546 gm. K_2HPO_4 was added to 2,100 ml. of an approximately 1 per cent solution of CO-myoglobin previously fractionated with ammonium sulphate and dialysed against distilled water according to Theorell[7]. The resulting precipitate was filtered off and the filtrate saturated with the above phosphate mixture added in small amounts. The pigment having spontaneously oxidized during these manipulations, the precipitated metmyoglobin was filtered off on a Buchner funnel and the phosphate fractionation was repeated three times. After the second fractionation the α-band of the carbon monoxide compound as measured by the Hartridge reversion spectroscope remained constant at 5793 A. Small quantities of a mixture of 9·5 parts K_2HPO_4 and 17·0 parts $NaH_2PO_4.2H_2O$ were added with mechanical stirring until a small permanent precipitate appeared. This was filtered off on a hardened filter on a Buchner funnel. On standing at room temperature for 2–12 hours the metmyoglobin crystallized from the filtrate in dark-brown crystals belonging to the orthorhombic system[9].

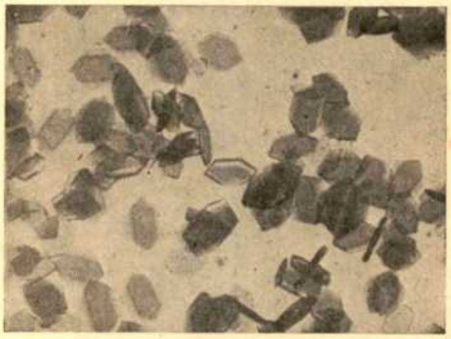

Fig. 1. Phosphate buffer. *p*H 5·7. 3·5 *M*. × 89

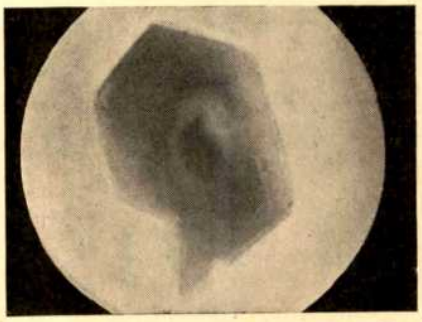

Fig. 2. Phosphate buffer. *p*H 5·7. 3·4 *M*. Large crystal. × 34

We wish to thank Prof. A. C. Chibnall for his interest in this work and Dr. J. G. Sharp of the Low Temperature Research Station for the whale meat. Thanks are also due to the Medical Research Council (J. K.) and to the Stiftung für Stipendien auf dem Gebiete der Chemie (K. S.) for personal grants.

THE COLONIAL MICROBIOLOGICAL RESEARCH INSTITUTE, TRINIDAD

THE ceremony of the opening of the Colonial Microbiological Research Institute in Port-of-Spain, Trinidad, British West Indies, was performed on July 5 by Lord Hankey, in the presence of a distinguished gathering including the Governor of Trinidad and Tobago, Sir John Shaw; the chairman of the Standing Closer Relations Committee, Sir Hubert Rance; Prof. J. L. Simonsen, director of research of the Colonial Products Research Council; the principal of the University College, Jamaica, Dr. Taylor; the acting principal of the Imperial College of Tropical Agriculture, Trinidad, Dr. Shepherd; and delegates from other Caribbean countries, from the United States, Mexico, Venezuela, Honduras, etc.

Introducing Lord Hankey, the Governor expressed his satisfaction at the presence of Lord Hankey and of so many distinguished delegates; on behalf of the peoples of Trinidad and Tobago he thanked Lord Hankey for having chosen Trinidad for this undertaking, which he understood was to serve as a research centre for theoretical and applied microbiology for the benefit of the Colonial Empire as a whole.

In a message read by Lord Hankey, Sir Robert Robinson, president of the Royal Society, conveyed the following greetings from the Royal Society: "It is impossible to visit any tropical or sub-tropical country without becoming more and more insistently aware of the importance of general microbiological research. In the field of the pathogenic organisms this need has long been recognized, and to some extent satisfied, but the importance of the wider aspect has not been equally well understood. Entirely inadequate provision has been made for such investigations whether from the point of view of pure biology, biochemistry, hygiene and medicine, or of industry. When Dr. Simonsen and I visited Trinidad in 1944, the need for extended microbiological research was obvious to us as a special instance of the general thesis. It was clear, too, that the facilities that could be made available, the side-contacts, and the general conditions were favourable for the development contemplated. Not only the health of the community in the physical sense, but also in the economic sphere, was seen to be tied up with microbiology in its wider implications.

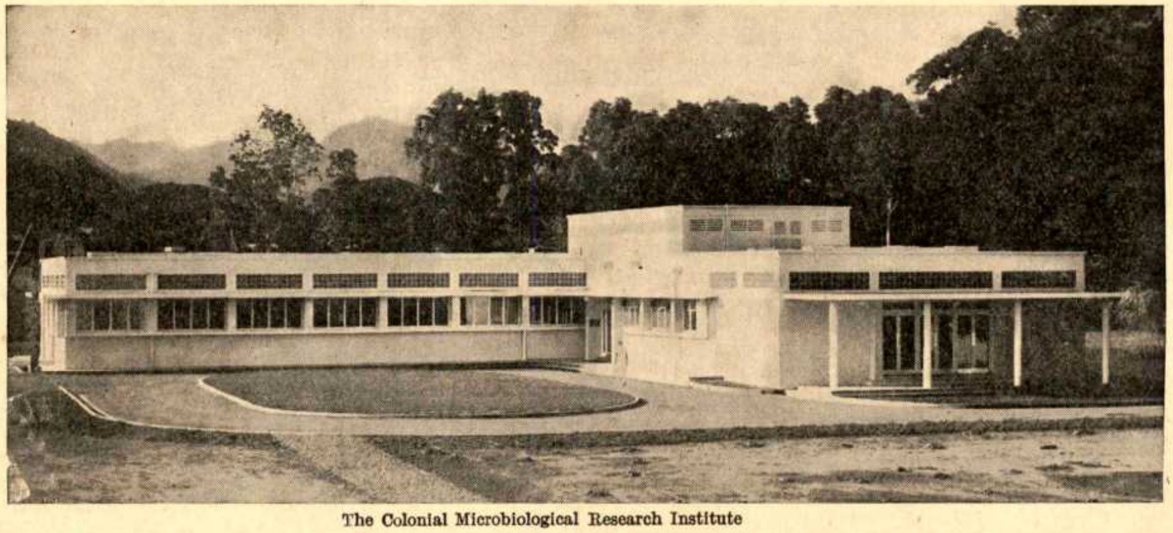
"On return to England, we found as a most fortunate and compelling circumstance that it might be possible to persuade Dr. Thaysen to undertake the organisation and first Directorship of a projected Institute for Microbiological Research. That was decisive and further steps taken are well known to you all. It is with real satisfaction that I send this message of felicitation to an Institute which I am sure is destined, not only to play an important part in the development of Trinidad and the Caribbean, but also to give an example to the rest of the world. It will surely make a significant contribution to science and we hope also to human happiness and prosperity."

In his address, Lord Hankey gave a brief review of British Colonial policy and organisation in scientific research and development in which the Institute is a link, and he sketched the history of the Institute's conception.

Amplifying Sir Robert Robinson's remarks, Lord Hankey asked: "Our aspirations! What are they? I dare not pitch them too high, or we may disappoint you. I must not pitch them too low, because, on a long view, they have no ceiling any more than has the blue firmament above Trinidad. But our first aspiration must be pure research; that wresting from Nature of her secrets; that process of getting to the bottom of things from which great results follow. Think of the pioneer work of Newton, of Faraday, of Herschel, of Pasteur, of Rutherford, and hundreds of others from which have been produced the marvels of modern science. Apply that thought to microbiology and you get some idea of our fundamental aims and ambitions for the microbiological institute.

"But we shall not limit ourselves to pure science. We shall continue, as hitherto, to exploit to the utmost the application of research for the benefit of mankind.

"It will interest you to know that, as the result of a recommendation by the British Commonwealth



The Colonial Microbiological Research Institute

Scientific Official Conference in 1946, the Microbiological Institute in Trinidad has become an official centre for the British Commonwealth for Culture Collections of Micro-organisms, where types of micro-organisms will be carefully preserved. That is essential if full advantage is to be taken of research in microbiology.

"I could give many further illustrations of what we have accomplished in our early, pioneer years, but I have said enough to give some impression of the kind of benefits we hope to derive from the pursuit of microbiology in this Institute; but in saying that, I must again emphasize that pure research must come first and that any deviation from that aim in pursuit of quick results might be calamitous."

Lord Hankey then went on to ask why Trinidad had been chosen for this important work. To begin with, he said, it was essential that the work undertaken in a new centre being intended mainly for the good of the tropical Empire should be undertaken within the tropics. "We were greatly influenced also," he continued, "by previous experience of the danger of placing such an Institute in isolation. Apart from the Caribbean Research Council, Trinidad already houses the famous Imperial College of Tropical Agriculture with its valuable library, and it seemed to us that to place the Institute within easy reach of the College should be of material benefit to both, owing to the close association with other scientists that each would enjoy. In this connexion it is very interesting that Dr. L. F. Wiggins, who has been prominent in assisting Sir Norman Haworth on the important work at Birmingham University on starch and sugar to which I have already referred, has recently been appointed by the West Indies Sugar Association as head of the new Department of Sugar Technology at the College. This should give a splendid start to the development of this branch of the College which was another of the suggestions made by Sir Robert Robinson and Prof. Simonsen.

"We had in mind also the opportunities that the Institute might afford for the important study of soil microbiology, and we did not overlook the prospects of invaluable contacts with the scientists of the Trinidad Government and of the refineries, oil companies and other industrial concerns in the island, as well as its associations, societies, and institutes. In particular we look forward to a close link with the University College of the West Indies.

"But to these more or less official reasons for the selection of Trinidad I would add one more, which makes a special appeal to me, as a layman, and is expressed in language more eloquent and more imaginative than I can command in the following passage from Charles Kingsley's 'At Last', chapter 14, entitled 'The High Woods', which was inspired by his observation of the Trinidad forest, while visiting the island in the last century: 'The eye is not filled with seeing, or the ear with hearing; and never would be, did you roam these forests for a hundred years. How many years would you need merely to examine and discriminate the different species? And when you have done that, how many more to learn their virtues, properties, uses? By what miracle they are compacted out of light, air and water, each after its kind? How, again, these kinds begin to be and what they were like at first? Whether these crowded, struggling, competing shapes are stable or variable? Whether or not they are varying still? Whether even now, as we sit here, the Great God may not be creating, slowly, but surely, new forms of beauty around us.' To sum up—in the words of Lucretius—'*Felix qui potuit rerum cognoscere causas*' (Happy is he who can know the causes of things. Lucretius, 'De Rerum Naturæ')."

After luncheon the company proceeded to the grounds of the Institute and here Lord Hankey unveiled a plaque with the name of the Institute engraved upon it, and opened the main entrance door with a key made of West Indian gold and presented to him by the architects who designed the buildings, Messrs. Watkins and Partners, of Bristol and Port of Spain. At the suggestion of the Director, Lord Hankey graciously consented to have his name associated with the culture collection maintained at the Institute as a link with Commonwealth culture collections of micro-organisms, and agreed that this culture collection in future should be known as "The Hankey Culture Collection" instead of the "Colonial Culture Collection".

A description of the Institute has already been given in *Nature* of July 3, p. 14.

Following the official opening, two morning sessions on July 6 and 7 were held in the library of the Institute. At the first of these Lord Hankey took the chair, and at the second, Prof. J. L. Simonsen. Many delegates and others read papers at these meetings, which were largely attended.

It is hoped, in due course, to compile an abbreviated account of the subjects dealt with in these discussions, and to issue them as a commemorative publication.

J. L. SIMONSEN

SOUND TRANSMISSION AND NOISE

A VERY successful symposium on sound transmission and noise was held during July 14–16 by the Acoustics Group of the Physical Society, with the kind co-operation of the Royal Institute of British Architects, in the Jarvis Hall of the latter, at Portland Place, London. The proceedings were opened by Mr. H. L. Kirke, chairman of the Group, and overseas visitors were present from the United States, France, Denmark, Holland, Sweden, Switzerland, Italy and Germany.

The opening session was devoted to problems of sound transmission. In the first paper, Dr. L. L. Beranek, of the Massachusetts Institute of Technology, described investigations he has been carrying out into the determination of the attenuation of single and multiple panels. To avoid the expense of the usual two-room method, he has developed a model test using panels 18 in. square giving results which agree well with full-scale tests and with theory. He has applied the theory to seven kinds of structures and has deduced charts which enable the attenuation, for partitions of known dimensions, mass and porosity, to be readily determined. Similar work in Great Britain at the National Physical Laboratory was described by Dr. G. H. Aston. He has not found any marked effect with size in the attenuation of glass windows, but there is an upper limit to the mass which it is worth while using set at 24 oz. glass by the compliance of the framing. With double windows there is an increase in attenuation with spacing even up to 7 in. at low frequencies, but 4 in. is sufficient at high frequencies. His work on plaster walls has shown a curious effect with time, the attenuation showing a cyclical variation during the first few days. He finds that strip metal ties for cavity walls provide much more coupling than wire 'butterfly' ties, especially at low frequencies.

Dr. Theodore Vogel, of the Centre National de la Recherche Scientifique, Marseilles, could not attend, but his paper on the transmission of sound by elastic panels was read by Prof. Canac. It gives a mathematical treatment of the vibration of a thin plate to waves of normal incidence using Lagrange normal co-ordinates. The resulting expression contains the simple piston result of Davis together with a term depending on the panel dimensions. Extensions of the theory to cases of double partitions and panels covered with porous coatings are given, and all the formulæ have been checked experimentally.

Mr. W. A. Allen, of the Building Research Station, Garston, Herts, traced the development of the party wall. The modern standard is an attenuation of 55 db., and no practical single-leaf construction has been found to give this. Two-leaf constructions of 3 in. and 4 in. thickness can reach the required standard; but it is necessary to give special attention to leakage paths, especially windows and chimneys.

Dr. Furrer, of the G.P.O., Berne, gave very interesting and useful information on the elastic properties of various materials in sheet or quilt form suitable for making floating floors to reduce impact sound. His results illustrate the good elastic properties of glass silk.

A joint committee representing Britain, Denmark and Holland has been formulating proposals for measuring insulation to air-borne and structure-borne sound, and these were put forward on behalf of the committee by Dr. Ingerslev, of Denmark. Air-borne insulation results should be corrected to a reverberation time of 0·5 sec. to match ordinary rooms. Impact sound insulation should be determined with closely specified apparatus, and subjective measurement is important. Analysers of ½ or ⅓ octave bandwidth are used and the results are summed. Dr. Aston described work at the National Physical Laboratory on the insulation of wood joist floors. Using a raft and pugging, he has attained 55 db. insulation to air-borne sound and 20 db. more than an ordinary floor to impact sound.

Measurements of impact sound at London, Copenhagen and Delft were described by Dr. Kosten. Discrepancies were removed by using the same tapping instrument, a 'Rawlplug' hammer.

A record of team-work by the National Physical Laboratory and Building Research Station staffs on the insulation of discontinuous structures was given by Mr. W. A. Allen. Mr. H. R. Humphreys described further work at the Building Research Station on floating floors, giving details of different constructions and results obtained in the laboratory and actual buildings.

The final paper for this session was read for Mr. Kipfer by Mr. P. Germain and described the method developed at the University of Brussels for measuring footsteps noises. In the discussion on the first day's papers, Prof. A. Giacomini made a plea for agreement on acoustical definitions and authors replied to questions, mainly on attenuation in structures. Cases of linear and geometric attenuation in decibels with distance were quoted.

The morning of the second day was devoted to papers of architectural interest, under the chairmanship of Mr. Hope Bagenal. Mr. W. A. Allen presented the results of a survey of domestic noise giving the proportion of people suffering in one way or another from noise. Banging doors appear to cause most trouble, but very careful framing of questions is necessary to obtain reliable information. He emphasized the strain due to self-imposed constraint on one's activities.

A large-scale investigation on a number of experimental flats at Rotterdam was described by Dr. Kosten. Several kinds of walls, ceilings and floors have been tried, together with resiliently isolated piping and sanitary installations. Dr. Kosten continued with a critical examination of similarity or scale tests, and his analysis shows the method to be very useful in determining sound insulation.

A short paper by Dr. J. L. Burn, medical officer of health, Salford, on noise in schools was read by Dr. King. The problem is outlined and results of noise measurements in typical schools are given.

Dr. Grunenwaldt's paper, also read by Mr. Germain, gives noise surveys of the ships *Prinz Albert* and *König Albert* and compares them with earlier surveys by Robinson. The engine rooms have been treated and show 102–106 phons.

Noise on board aircraft as it affects telephony was discussed by Mr. P. Chavasse, chief engineer of the Acoustic Department, Centre National d'Études Télécommunications, Paris. His paper gives general directions for improving telephonic communication on board and includes an analysis of the origin and nature of the various noises.

A complementary paper to Mr. Allen's on domestic noise was read by Mr. P. H. Parkin, also of the Building Research Station, on insulation of flats from sound. The complete programme outlined begins, logically, with a social survey, discusses methods of measurement of attenuation of air-borne and structure-borne sound and gives test results on typical constructions.

Prof. Canac's paper, which he gave in French, on the acoustics of ancient Greek and Roman theatres, came as a welcome change to many present. His studies of the theatres of Orange and Vaison have shown the importance of the various structural features and point out lessons. The relation between the various absorption coefficients was discussed by M. Grunenwaldt. His paper gives the experimental basis for a relation between the Taylor and Sabine coefficients.

In the ensuing discussion, Dr. Beranek referred to the calculation of loudness from analyses and Dr. King outlined the method, originally due to Dr. B. G. Gates, which he uses. Dr. Mintz, U.S.A. Navy Department, suggested an accelerometer instead of velocity meter for similarity tests.

The morning of the third day was devoted to noise measurement, the chairman being Mr. W. West. The opening paper by Mr. R. S. Dadson, of the National Physical Laboratory, gives a survey of the problem of noise measurement, outlining the difficulties in making measurements in the field in terms of the fundamental unit of equivalent loudness. He compares the performance of objective and subjective meters particularly on motor-car exhaust noise, and points out the necessity for general agreement on equal loudness contours and the summation of analyses.

Dr. A. J. King's paper on a portable objective noise meter refers briefly to the errors of sound-level meters on complex noises and describes a much simplified peak/R.M.S. meter. Readings on typical noises are compared with subjective and sound-level meters showing less errors than the latter.

A mains-driven meter operating on the same principle was described by Mr. D. A. Nutt. This instrument conforms to the standards of the Acoustical Society of America but also incorporates peak/R.M.S. measurement. It is intended for routine factory use.

M. P. Baron gave his paper on objective noise measurement in French. He feels that objective meter readings and summations from analyses are unreliable and should be confined to comparing similar noises.

In his paper, Mr. Maurice, of the B.B.C., deals with a different aspect of noise, namely, interference with broadcast reception. He has correlated subjective assessment of interference with readings by various meters and finds a weighted energy meter gives the closest correlation.

The paper by Lord Halsbury describing a rapid wave analyser was read in his absence by Mr. D. G. Jaquess. The instrument is a heterodyne analyser covering 0–30 kc./s. with provision for sweeps of $\frac{1}{4}$ to $\frac{1}{8}$ sec. and maximum resolution. It also permits more detailed examination of a 2 kc./s. band.

In his paper on the reduction of noise in aircraft, Mr. N. Fleming, of the National Physical Laboratory, deals with the contributions from the engine, propellers, aerodynamic flow and auxiliaries. He has studied octave frequency bands in each case and he shows the effects of power, tip speed and air velocity.

M. P. Chavasse read his paper describing an apparatus to produce complex sounds and artificial voices for acoustic tests in French. It is based on valve noise with suitable modulation to simulate the voice. Results obtained with it agree well with those for the natural voice.

In the discussion after this session, Dr. Beranek described recent work in the United States tending to confirm the level high-intensity equal loudness contours. He questioned the differences between pressure and field sensitivities of the ear, hinting at an obscure effect. He also asked for terminological agreement on 'random' and 'white' noise. Mr. Fleming objected to the indiscriminate use of phons for decibels, and Dr. Furrer asked about the calculation of loudness from analyses.

For the final session Mr. Kirke was again in the chair, and papers covered a wide range of applied acoustics. First, Dr. L. Cremer, who had only just arrived from Munich, read his paper on sound insulation at oblique incidence. Consideration of the travelling waves along a panel with a sound at oblique incidence suggested to him that grooves in the panel would improve attenuation. His paper gives the theory and experimental confirmation.

Dr. Kosten had had to return to Holland, so the joint paper on sound absorption in layers of material was read by J. van den Eijk. The paper gives the theoretical performance of such layers and includes experimental confirmation.

In his paper on noise in air ducts, Dr. Grunenwaldt gives the results of noise measurements on several ventilation systems with various air velocities and duct lengths. These data enable him to design duct systems for given room noise conditions.

The paper by Dr. A. Schoch, of Göttingen, on absorption by gradual transition gives the theory for successive layers of material of increasing density, leading up to the modern wedge construction. He takes as an example a linear wedge structure and gives curves for its performance.

Mr. C. A. Mason described the development of quiet chokes for use with fluorescent lamps. His paper examines the essential causes of the noise—magnetostriction and bad joints—and shows the stages followed in their reduction. He also considers the noise of a number of chokes.

In his paper on the elastic properties of rubber, Dr. E. Meyer, of the University of Göttingen, describes an elegant method using a sample in a resonant column of liquid. This gives bulk modulus and dissipation, while Young's modulus is given by longitudinal resonance or travelling waves. The frequency range covered is 10 c./s. to 20 kc./s. Effects of temperature and load are also discussed.

Mr. C. H. Bradbury's paper discusses the noise of machines, especially Diesel engines. He gives noise spectra and considers the pitched and unpitched components. He emphasizes the shock excitation of damped systems and uses a loud speaker to show up resonances. He also considers the effect of background noise.

Owing to the unavoidable absence of Prof. P. Bruel, Dr. V. L. Jordan, Mr. E. N. Storr and Mr. R. S. Hogben, their papers were not read but will be published in the *Proceedings*.

There were many contributors to the closing discussion. Among them, Mr. Fleming quoted work at the National Physical Laboratory disagreeing with Dr. Cremer on grooves and he also suggested that 'frequency of troubling' should be included in Mr. Allen's questionnaire. Mr. Mason asked about the critical frequency between dynamic-static properties of rubber, and Dr. Meyer gave it as 1 or 2 c./s. Dr. King said he was investigating the matter and thought it would be nearer 0·1 c./s. M. Brillouin gave a humorous contribution suggesting that the phon is insufficiently defined for practical purposes, but Mr. Fleming, chairman of the British Standards Institution Committee on Noise Measurement, gave a convincing reply.

A. J. KING

MIDDLE EAST OIL

THE name of that distinguished American geologist and statistician, Dr. Everette de Golyer, has been proverbial in international oil technology for many years past. He has an almost uncanny flair for predicting correctly the trend of events in the petroleum world, and his forecasts on developments in those countries comprising the Middle East are no exception. So long ago as 1925 the writer remembers de Golyer saying that "he expected from Persia a continued increase in production, as handling and marketing facilities are increased, so long as the fields may last". Nearly twenty years later, when leader of the United States Petroleum Commission to the Middle East, he stated that "the centre of gravity of world oil production is shifting from the Gulf – Caribbean area to the Middle East and is likely to continue to shift until it is firmly established in that area". That this has actually happened is probably not generally appreciated: the economic, technical and political implications of the fact have yet to be assimilated by the public, quite apart from the industry itself. To this end an up-to-date, straightforward survey of the position is essential to its understanding, and the *Petroleum Times* has rendered signal service by publication of its "Review of Middle East Oil" (London, June 1948, 7*s.* 6*d.*).

This review is not a mere compilation. It presents 'eye-witness' accounts of the shape of things concerning oil in Iran, Iraq, Bahrein, Saudi Arabia and Kuwait as they are to-day. It is based fundamentally on a two-months tour of the oilfields at the close of 1947 undertaken by Dr. C. T. Barber, joint editor of the *Petroleum Times*, with reinforcements by Dr. G. M. Lees, chief geologist of the Anglo-Iranian Oil Company, Ltd., Max Weston Thornburg, war-time petroleum adviser to the U.S. State Department, Christopher Holme, well-known writer and broadcaster on Middle East affairs, and T. D. Weatherhead, technical manager, Hunting Aerosurveys, Ltd.

Consider first some vital statistics that emerge from this survey. In 1936 the proved oil reserves of the world were proportioned as follows: U.S.A., 48·1 per cent; Middle East, 21·1 per cent; U.S.S.R., 12·9 per cent; Caribbean and Mexico, 9·7 per cent; and the rest, 8·2 per cent. In 1944 the figures were 33·9, 42·3, 9·0, 10·0 and 4·8 per cent, respectively. Thus in eight years Middle East reserves were doubled. Next are the production figures. In 1936, the U.S.A. produced 60·7 per cent, Middle East 5·4 per cent, U.S.S.R. 11·9 per cent, Caribbean and Mexico 13·2 per cent, and the rest 8·8 per cent of the world total output of crude oil. In 1947 the figures were 63·6, 9·8, 5·5, 17·3 and 3·8 per cent, respectively. Again, in the intervening years, Middle East nearly doubled its production. Further, with 42 per cent of world reserves, the Middle East produces 10 per cent of world output and in 1947 was drawing on reserves at the rate of 1·14 per cent per annum. By contrast, the United States with 33·9 per cent reserves produce 64 per cent of world output and are drawing on reserves at the rate of 9·25 per cent per annum. Still more striking, as Dr. Barber shows, is the fact that in 1947 Middle East production of 306 m. barrels was obtained from 223 wells, an average of 1·37 m. barrels per well, whereas the United States production of 1,985 m. barrels was obtained from more than 425,000 wells, an average of 4,660 barrels per well.

It is commonly believed that the present drastic rationing of petrol in Great Britain is a post-war legacy and a dollar-saving necessity. Why, it is asked, if we control such enormous oil production in the Middle East, is petrol so short in Britain, and why import from the Americas? The fact is that dollar-saving is not the whole story by any means. All over the world people are using more and more oil. In 1947 the American demand was 73·1 per cent more than in 1938; the demand in Great Britain was 45·3 per cent more; the British Commonwealth as a whole consumed over 100 per cent more, while other countries increased their demand by 17·2 per cent. In other words, the world oil demand has increased more than 50 per cent in the nine-year period, accounted for largely by heavily increased requirements of the United States for military, agricultural, domestic and transport purposes. C. J. Bauer has estimated that world demand in 1951 will be 23·4 per cent greater than that for 1947, and to meet this unprecedented rise the Middle East fields will have to increase production by 100 per cent by that year. From all that transpires in the present "Review of Middle East Oil" there appears to be no reason why this should not happen, particularly as the European Recovery Plan allows for 82 per cent of Western European demands for petroleum being met from Middle East resources in 1951.

Besides the purely economic aspects, technical developments of a high order of efficiency will be essential if the 1951 target is to be reached. In this direction optimism is well sustained, if past history of this great oil province is anything to go by. The achievements of the oil companies concerned, not excepting the cultural and social evolution of the native populations, constitute alike a fine record and a model of how things should be done in all spheres of exploiting mineral resources in virgin territory. The "Review" covers these activities and illustrates them, too, in a most convincing manner. It is a valuable publication, one to be commended to all who wish to understand the present problem of oil supply and its vital incidence on international politics in these critical times.

H. B. MILNER

CONCENTRATION OF COBALT BY MICRO-ORGANISMS AND ITS RELATION TO COBALT DEFICIENCY IN SHEEP

By Dr. J. TOSIC
Rowett Research Institute, Bucksburn, Aberdeenshire
AND
Dr. R. L. MITCHELL
Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen

WORK on wasting diseases in Australia[1,2] and New Zealand[3], and 'pining' in the United Kingdom[4,5], has established that cobalt is an essential factor in ruminant nutrition. Deficiency of cobalt results in various wasting diseases, the literature of which has been adequately reviewed[6,7,8,9]. In contrast to the ruminant, it appears that non-ruminants, for example, the rat[10] and the rabbit[11], require very little, if any, cobalt in the diet, for they can thrive on diets containing cobalt in concentrations much below those which would cause wasting diseases in ruminants.

Recent work[12,13], in which radioactive cobalt was injected intravenously into adequately fed cattle, showed that most of the isotope injected was excreted in the urine, and that only small amounts were found in the milk and saliva and none in the rumen content; radioactive cobalt introduced directly into the rumen was excreted chiefly in the fæces, and none was detected in the blood, saliva or milk, thus suggesting relatively poor absorption of the element. Although it is known that the liver is the storage organ for cobalt in sheep[14] and cattle[13], and that the cobalt content in the liver of a cobalt-deficient sheep is considerably lower than that in a healthy sheep on good pasture[14], the mechanism of the action of cobalt in animal nutrition remains still unknown. Using an as yet unpublished procedure[15] for the separation of rumen micro-organisms and other fractions of the rumen contents, and after chemical concentration[16] applying a spectrographic method[17] to the quantitative determination of cobalt in the rumen fractions, we have been able to demonstrate that rumen micro-organisms accumulate cobalt from their external environment. Since we find that a large proportion of the cobalt present in the rumen of a sheep is situated in the rumen micro-organisms, it is possible that in cobalt-deficient sheep the host and the microbial population of its rumen compete for the already low concentration of cobalt available in the feed, and in this way accentuate a deficiency at the place(s) of its physiological function.

In this work we have used three sheep with rumen fistulæ[18]. One, a two-year-old wether (*A*), gained weight on a seeds hay diet (0·27 p.p.m. cobalt in dry matter). The other two wethers, kindly placed at our disposal by Dr. A. T. Phillipson, of the Rowett Institute, and bred originally on a cobalt-deficient pasture, were maintained on a hay diet containing only 0·07 p.p.m. cobalt in dry matter but otherwise adequate. One of these animals (*B*) remained in poor condition (weight at 10 months, 60 lb.) and served as control, while the other (*C*) was dosed daily (during the morning feeding) with 1 mgm. Co (as cobalt chloride) for a period of six weeks. At the end of this period, when sheep (*B*) and (*C*) were about ten months old, rumen contents were collected (10 hr. after last feed) and fractionated. The fractions separated were examined microscopically and were as follows: fraction I, consisting mainly of protozoa and large rod-shaped bacteria, some smaller bacteria occurring singly, in chains, sarcina-like and in other irregular formations, in addition to a fair proportion of finer plant particles; fraction II, similar in microscopic appearance to I but almost completely free from protozoa and plant particles; fraction III, consisting principally of small cocci occurring mostly singly; fraction IV, consisting of coarser plant particles almost free from micro-organisms adhering to their surfaces; and fraction V, consisting of the supernatant rumen liquid after the separation of fractions I–IV, containing a small proportion of rumen micro-organisms still remaining suspended in the liquid. There was no marked difference in microscopic picture in comparable fractions separated from sheep *A*, *B* and *C*. The total dry matter, and nitrogen, ash and cobalt (on dry matter basis) were determined for each fraction, but for brevity only figures for cobalt are given (Table 1) in this preliminary note.

Our data show that, in the adequately fed sheep (*A*), the cobalt content of the micro-organisms is some three times the cobalt content of similar microbial fractions from the rumen of a sheep (*B*) consuming cobalt-deficient hay. But in sheep (*C*) consuming cobalt-deficient hay and dosed with 1 mgm. cobalt daily, the cobalt content of the microbial fractions is about five times that of a similar sheep (*B*) receiving no cobalt supplement. When cobalt contents of microbial fractions I, II and III are compared with those for the respective supernatant rumen liquids (cobalt content of which in *A* and *B* is probably contributed mainly by the remainder of suspended micro-organisms and in *C* by the daily dosage of cobalt supplement), and the hay fed, it is apparent that rumen micro-organisms concentrate cobalt from their external environment.

Table 1. Cobalt contents of microbial and other fractions separated from rumen contents of sheep fed cobalt-adequate hay or cobalt-deficient hay with or without addition of cobalt (as p.p.m. Co in dry matter)

Fraction	Sheep fed on:		
	(*A*) Adequate hay	(*B*) Cobalt-deficient hay with no cobalt added	(*C*) Cobalt-deficient hay with 1 mgm. cobalt added daily
Microbial (I)	1·85	0·58	3·51
Microbial (II)	3·81	1·49	5·70
Microbial (III)	3·80	1·55	8·25
Plant particles (IV)	0·19	0·12	4·00
Supernatant liquid (V)	0·12*	0·16*	1·94
Total rumen contents before fractionation	0·67	0·29	2·22
Hay as fed	0·27	0·07	0·07

* Probably due mainly to residual suspended micro-organisms.

Using our results in order to calculate the contribution of each of the separated fractions towards the dry matter of the unfractionated rumen contents, in Table 2 cobalt data are derived for each fraction in terms of micrograms of cobalt per 100 gm. of fresh rumen contents and as percentage recovery from, and distribution in, total rumen content. Good agreement has been obtained between the total cobalt in the rumen contents and the sum of the contributions of the individual fractions. From Table 2 it is seen that most of the cobalt found in the rumen contents is found in rumen micro-organisms (about 80 per cent in undosed animals), and that only a small proportion of the total cobalt is found in the external environment (fractions IV and V), except in sheep *C*, where greater amounts of cobalt were present in the supernatant fluid, due to the daily cobalt dosage.

From our findings it appears that, in sheep, the cobalt content of the microbial population of the rumen is related to cobalt concentration in the diet. If cobalt is essential for micro-organisms, but not for the host, then absorption of the element by the host

Table 2. Distribution of cobalt in separated fractions from rumen contents and contribution of those to the total rumen contents

Fraction	Sheep fed on:					
	(*A*) Adequate hay		(*B*) Cobalt-deficient hay with no cobalt added		(*C*) Cobalt-deficient hay with 1 mgm. cobalt added daily	
	μgm. Co/100 gm. rumen content	% of total rumen content	μgm. Co/100 gm. rumen content	% of total rumen content	μgm. Co/100 gm. rumen content	% of total rumen content
Microbial (I)	1·13	39·5	0·69	52·3	3·67	31·1
Microbial (II)	0·34	11·9	0·10	7·6	0·55	4·7
Microbial (III)	0·95	33·2	0·40	30·3	2·63	22·3
Microbial total	2·42	84·6	1·19	90·2	6·85	58·1
Plant particles (IV)	0·39	13·6	0·22	16·7	1·98	16·8
Supernatant liquid (V)	0·15*	5·2*	0·21*	15·9*	2·49	21·1
Total of individual fractions	2·96	103·5	1·62	122·8	11·32	96·0
Total rumen contents before fractionation	2·86	100·0	1·32	100·0	11·80	100·0

* Probably due mainly to residual suspended micro-organisms.

would deprive the micro-organisms of a factor essential for their growth and/or metabolism. It may even be that pining and other wasting diseases are due to cobalt deficiency of the bacteria, the animal requiring not cobalt but the bacterial products which have thereby become deficient. If cobalt is an essential metabolite for the host alone, then its concentration in micro-organisms may reduce its availability for the host. In this connexion it is of great interest that cobalt has been found to occur to the extent of 4·0 per cent of the crystals (dried *in vacuo*) of the naturally occurring anti-pernicious anæmia factor[19]. It is possible that both the host and the microbial population of its alimentary canal require cobalt for their respective metabolic activities. On a low cobalt diet these competitive relations may assume some importance in the etiology of cobalt-deficiency diseases. How far cobalt found in rumen micro-organisms, after leaving the rumen, can be made available for absorption by the host or for intake by its microbial population in the lower parts of the alimentary canal, and with what result, remains to be shown experimentally, together with the points raised earlier.

Full details of this work involving a study of several trace elements in rumen micro-organisms, and certain pure cultures of bacteria and yeasts, will be published elsewhere.

LARDER OF THE RED-BACKED SHRIKE

MR. J. H. OWEN has given some interesting information about a bird the habits of which are little known to present generations because the bird has become so scarce (*British Birds*, **41**, No. 7; July, 1948). From observations it would appear that all red-backed shrikes (*Lanius c. collurio*) make larders provided they do not need the catch when it is taken. The male bird seems much more given to 'lardering' than the hen, and as many as six larders may be used by one pair of birds. Usually the larders are not far from the nest, but some have been reported 150 yards away. Often the number of larders is one or two. Shrikes prefer to nest in one of a number of isolated bushes, provided one of them is suitable, rather than in a hedge. Hedgerow larders are usually not at all easy to find. The favourite bushes are hawthorn or blackthorn, especially a part that has been killed by fire or some other means. The large thorns on rough briars and brambles are frequently used as larders, and occasionally barbed wire is also used. Larders often have a considerable number of humble-bees (*Bombus*) in them, often a small bird and, occasionally, a house-mouse (*Mus domesticus*) is found.

Queen humble-bees figure prominently in the larders. The birds usually devour workers and males, carder bees and honey bees (*Apis*) as they catch them. Sometimes wasps (*Vespa*) are taken and the remains found in pellets; but it is rare to find a wasp in a larder. Dor-beetles (*Geotrupes*) and cockchafers (*Melolontha*) are seen pinned up. Insects are usually pinned through the underside of the thorax, back uppermost; but occasionally some are pinned through sideways or through the back. The victims are often found alive. Larders are more likely to contain food at night than in the morning, and on cold misty mornings the larder that was well stocked at night is often empty. Among the young birds which were found were willow-wrens (*Phylloscopus trochilus*), whitethroats (*Sylvia communis*), linnets (*Carduelis cannabina*), and pipits (*Anthus*), while common lizards (*Lacerta vivipara*), field-voles and wood mice (*Apodemus sylvaticus*) are also taken.

The larder is used for other purposes than feeding. Often the old birds will carry sacs of excrement from the nest and place them on the tips of thorns in a regular larder. This always occurs when pellets are thrown up by the young. Attempts have been made to pin up dead small birds and mammals in the larders. Observations have shown that these have never been pinned up to the satisfaction of the shrikes, and usually a cock bird pulls the bodies free and fixes them elsewhere. There is a certain amount of evidence to show that the hen fetches food from the larder much more than the cock, although he alone may provision it. Both may use it to cram the young before a thunderstorm, for example, or if they have been kept away from the nest for some time.

T. H. HAWKINS

WAVE MECHANICS IN SCIENTIFIC RESEARCH

PROF. C. A. COULSON'S inaugural lecture as the first professor of theoretical physics at King's College, London, which he delivered on March 2, 1948, is printed in full in the July issue of *Science Progress* (**36**, 436; 1948). Taking as his subject, "Wave Mechanics in Physics, Chemistry and Biology", Dr. Coulson shows, by several well-chosen examples, that wave mechanics, in spite of its early successes, does not provide neat, complete solutions to all physical and chemical problems, thus obviating experimental research; but, as a branch of theoretical physics, is most useful in correlating different pieces of information and in bringing out the essential underlying character of what is observed and measured.

From de Broglie's concept of a particle as a wave, enunciated in 1924, Schrödinger in 1926 treated the simple case of the non-relativistic and unperturbed hydrogen atom and introduced the wave equation, that equation which replaces the ordinary Newtonian equation of motion of the particle. He showed that the rules of quantization were automatically obeyed. The subsequent generalization and wide application of Schrödinger's wave mechanics proved remarkably successful, but there were limitations. One-electron problems or problems with separable variables could be dealt with; but the equations for H_2, the simplest molecular problem, or for the reaction $H + H_2 \rightarrow H_2 + H$, which is the simplest three-electron problem of chemical interest, to say nothing of the more complicated problems of large molecules, are insoluble. These severe limits to the complete calculation of almost any single physical or chemical property led to considerable despondency, and this despondency, it is Dr. Coulson's belief, is due to a wrong conception of the true function of wave mechanics. "Wave mechanics", to quote Dr. Coulson, "is the key—or perhaps *a* key—to the future of physics, chemistry and biology. However, when we open doors with it we do not find completely worked out, neat solutions to all our problems, but new ideas, new principles, new understanding of processes the details of which we shall probably never calculate to 'so many' significant figures, and new relations between apparently unrelated properties."

The examples chosen by Dr. Coulson to illustrate his meaning are taken from fields in which he has made important contributions. They include: atomic and molecular structure, referring briefly to stereochemistry, and to the structure of benzene, which introduces the general phenomenon of 'resonance' and the idea of fractional bond order; electrons in metals, and the understanding of conduction, photo-conduction, fluorescence, etc., which has resulted from the idea of bands of energy-levels but without the band distribution of any single metal ever having been completely calculated; colour; chemical reactions; and finally, the very large molecules from which the nature of life may be determined.

THE HATHERLY BIOLOGICAL LABORATORIES, UNIVERSITY COLLEGE, EXETER

By PROF. JOHN CALDWELL

THE foundation stone of the Hatherly Biological Laboratories of the University College of the South-West, Exeter, was recently laid by the Marquess of Salisbury, president of the College, in the presence of representatives of the County, the City and the College. When the building is completed, as it is hoped, within the next two years, it will accommodate the Departments of Botany and Zoology, which are, at present, housed in very inadequate and cramped quarters in the Old College buildings in the centre of the city.

The War has, of course, greatly impeded the development of the College as regards buildings, and the estate which the College acquired some twenty-five years ago affords great opportunity for building development, though inevitably that development must be temporarily delayed. It is fitting, therefore, that the first of the post-war buildings should be for the Biological Departments in a College which serves primarily an essentially agricultural area, so that these Departments may have adequate space for the development of their work in the service of the community.

The erection of the Laboratories has been made possible by a bequest of the estate of Mrs. Heath, supplemented by grants from the University Grants Committee. The teaching and research work of the biological departments has expanded very greatly from the time of the appointment of the late J. L. Sager as head of the Department of Biology in the Royal Albert Memorial College in 1907. The scope of the Department increased rapidly right from the beginning, and in 1928 a Department of Zoology was set up under Dr. G. Lapage, who was succeeded on his appointment to Cambridge by Mr. L. A. Harvey, the present head of the Department of Zoology. Mr. Sager continued as head of the Department of Botany until his retirement in 1935, when he was succeeded by the present writer, who had previously been on the staff of the Department of Plant Pathology at Rothamsted Experimental Station. Both Departments in the College, as is common to all university departments at present, are overcrowded and badly in need of additional accommodation.

When the new Laboratories are completed, each Department should have adequate accommodation for reasonable expansion. Each will have three large main laboratories and a small laboratory for honours students, with adequate private rooms, preparation and lecture rooms. There will also be a large lecture room, museum accommodation and dark rooms, tank and constant-temperature rooms for general use.

The building, which is designed by Mr. E. Vincent Harris, is in the form of a main block with private rooms and caretakers' quarters on the front, with five bays running back from it in which are situated the laboratories. This arrangement will allow of the maximum of light being available in the laboratories without having a south exposure.

As the site is on the College estate on the outskirts of the city, there is a considerable amount of ground available behind and around the building, which it is proposed to lay out for botanical collections and experimental ground with glasshouses. The whole should eventually form an ideal unit for biological investigation and teaching. The Departments have now, even under the present conditions, a wide range of research work on hand. On the botanical side, various aspects of virus diseases are being studied, both on the more general side and on diseases of specific crop plants common in the region.

Other phytopathological work includes the study of the ecology of fungi in relation to plant disease, investigation of the Erysiphales, and of the rust of *Chrysanthemum* and similar studies. The cytology of various plants is being investigated as well as more general cytogenetical subjects. At the same time there is a considerable amount of work being done on the cultivation of various plants of some economic importance, and a study of their anatomy and physiology in relation to different cultural methods. It is hoped also to expand and develop an ecological survey of a portion of Dartmoor.

On the zoological side investigations are being carried out on the ecology of areas in the south-west with special reference to Lundy, on some aspects of parasitic protozoology and on some problems of human fertility.

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Tuesday, September 28

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. Paul Bloomfield: "The Eugenics of the Utopians; the Utopia of the Eugenists".*

Tuesday, September 28—Thursday, September 30

Society of Chemical Industry (at the University, Leeds).—Conference on "Dust in Industry".

Tuesday, September 28

At 9.30 a.m.—"Physical Characteristics and Estimation of Dust"; at 2.30 p.m.—"Practical Aspects of the Dust Problem", Part 1.

Wednesday, September 29

At 9.30 a.m.—"Practical Aspects of the Dust Problem", Part 2; at 2.30 p.m.—"Fire and Explosive Hazards".

Thursday, September 30

At 9.30 a.m.—"Health Hazards"; at 2.30 p.m.—Summation of the Work of the Conference.

Wednesday, September 29

Television Society (at the Royal Institution, Albemarle Street, London, W.1), at 6.30 p.m.—Mr. Arthur Blok: "Some Personal Recollections of Sir Ambrose Fleming" (Third Fleming Memorial Lecture).

Society for Visiting Scientists (joint meeting with A.S.L.I.B., at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Dr. F. R. Ranganathan: "Self-Perpetuating Classification—the Need and Possibility".

Wednesday, September 29—Thursday, September 30

Institute of Welding.—Autumn Meeting.

Wednesday, September 29

At 2.30 p.m. (at the Institution of Civil Engineers, Great George Street, London, S.W.1).—Discussion on "Technical Training for the Associate-Membership Examination of the Institute" (to be opened by Mr. T. R. B. Sanders).

Thursday, September 30

At 10.30 a.m. (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1).—Dr. H. G. Taylor: "Some Aspects of Welding Research in Great Britain and America" (Session arranged by the British Welding Research Association); at 2.30 p.m.—Discussion on "The Training of Welders" (to be opened by Mr. F. Clark, Mr. S. W. Carpenter and Mr. R. J. Fowler); at 6 p.m.—M. André Goelzer: "Repair and Reinforcement of Metal Bridges by Welding".

Thursday, September 30

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Mr. Peter G. Masefield: "Some Economic Factors in Civil Aviation, with Emphasis on Civil Aircraft and their Prospective Trends of Development" (Fourth British Commonwealth and Empire Lecture).

Royal Statistical Society, Sheffield Group of the Industrial Applications Section (in Room B 1, Department of Mechanical Engineering, The University, St. George's Square, Sheffield), at 6.30 p.m.—Symposium on "The Limitations of Statistical Methods".

Saturday, October 2

Society of Public Analysts and other Analytical Chemists, North of England Section (joint meeting with the Physical Methods Group, at the Stork Hotel, Queen Square, Liverpool), at 2 p.m.—Scientific Papers.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Technician to take charge of the Medical Unit Laboratory—The Secretary, St. Mary's Hospital Medical School, Praed Street, London, W.2 (October 1).

Scientific Officer (male) for work on cereal breeding, a Scientific Officer for work dealing with virus diseases of potatoes, and a Scientific Officer to work in collaboration with other members of the plant breeding staff on genetical and cytological problems—The Secretary, Scottish Society for Research in Plant Breeding, 8 Eglinton Crescent, Edinburgh 12 (October 2).

Lecturer (man or woman) in Agricultural Sciences, and a Lecturer (man) in Agriculture (farm implements, building construction, etc.), at the Cheshire School of Agriculture, Reaseheath, Nantwich—The Director of Education, County Education Offices, City Road, Chester (October 2).

Responsible Lecturer in Mechanical Engineering, a Lecturer in Mechanical Engineering, and a Lecturer in Mathematics for engineering students—The Principal, Royal Aircraft Establishment Technical College, Farnborough, Hants (October 2).

Assistant Agricultural Economist *or* an Investigational Officer and Clerk Accountant—The Registrar, The University, Leeds 2 (October 4).

Research Assistantships (2) for work on (*a*) physical and chemical aspects of selective flotation, and (*b*) mining research problems—The Registrar, The University, Leeds 2 (October 4).

Assistant Advisory Officer in Agricultural Botany—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh 8 (October 9).

Laboratory Technician in the Department of Organic Chemistry—The Registrar, The University, Liverpool (October 9).

Mechanical and Electrical Engineers in the Higher Departmental Grades in the Ministry of Supply—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1 (October 12).

Research Officer to undertake research and assist in the work of the Photometry Laboratory (Ref. No. 1917), a Research Officer to assist in physical investigations at low temperatures (Ref. No. 1918), and Research Officers (2) to undertake research on the physical properties of wool fibres and related materials (Ref. Nos. 1919 and 1920), in the C.S.I.R. Division of Physics, Sydney—The Chief Scientific Liaison Officer, Australian Scientific Research Liaison Office, Africa House, Kingsway, London, W.C.2, quoting the appropriate Ref. No. (October 16).

Research Officer in the C.S.I.R. Division of Industrial Chemistry, Melbourne, to assist in the X-ray crystallographic investigations of the Division's Chemical Physics Section—The Chief Scientific Liaison Officer, Australian Scientific Research Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Ref. No. 1913 (October 16).

Brotherton Research Fellowship in Physical Chemistry, and the Bradford Dyers' Association Research Fellowship—The Registrar, The University, Leeds 2 (October 18).

Assistant Professor in Inorganic Technology at the Faculty of Engineering, Fouad I University, Giza, Egypt—The Director, Egyptian Education Bureau, 4 Chesterfield Gardens, London, W.1 (October 18).

Mechanical Production Engineer, and Mechanical Design Engineers (2), for the G.P.O. Engineering Department (Research Branch), Dollis Hill, N.W.2—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2288 (October 21).

Technicians (2) in the Engineering Research Laboratory; Technicians (4) in the Standards Laboratory; a Senior Mechanical Draughtsman and Mechanical Draughtsmen (2) in the Design Section; a Technician in the Workshops Planning Section; Toolmakers (4) in the Machine Room, and a Leading Hand Toolmaker and a Toolmaker in the Grinding Room, of the Precision Metal Workshop; a Technician in the Electrical, Electronics and Acoustics Laboratory; and Technicians (2) in the Instrument Testing and Development Section; of the Dominion Physical Laboratory at Wellington—The Office of the High Commissioner for New Zealand, 415 Strand, London, W.C.2 (October 30).

Life Fellowship in Botany—The Registrar, Trinity College, Dublin (January 1).

Entomologist in the Medical Department (Sleeping Sickness Service), Nigeria—The Director of Recruitment, Colonial Service, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Works Chemist to undertake production and/or development responsibilities on shift work (if necessary) in a chemical factory of the Department of Atomic Energy, Springfield's Factory, Salwick, Preston—The Staff Section, Ministry of Supply, Department of Atomic Energy, Risley, Warrington, Lancs.

Technicians (2, Grade III) in the Department of Botany—The Secretary, University College, Gower Street, London, W.C.1, quoting "Botany/1".

Laboratory Technician (Grade B) in the Department of Pharmacology—The Secretary, Medical College of St. Bartholomew's Hospital, West Smithfield, London, E.C.1.

Senior Research Worker (with extensive experience in modern biochemical or experimental physiological methods as applicable to research in psychiatry)—The Medical Superintendent, Bristol Mental Hospital, Fishponds, Bristol.

Physical Chemist or a Physicist to undertake fundamental work on metal finishing problems including electrodeposition and electropolishing—The Secretary, British Non-Ferrous Metals Research Association, 81–91 Euston Street, London, N.W.1.

Instrument Makers (2, Grades I and II) in the Department of Electrical Engineering—The Secretary, University College, Gower Street, London, W.C.1, quoting "Elec. Eng./1".

FREEDOM AND OBLIGATIONS

IN the summary of the proceedings of the meeting of the Committee on Science and its Social Relations held in Paris during June 15–16 which has been sent to the scientific press and to scientific organisations, special emphasis is placed on a declaration on the principles of a charter for men of science. This declaration is the outcome of a discussion on the obligations and rights of scientific men in which due note was taken of the charter proposed by the World Federation of Scientific Workers and of a resolution adopted by the General Assembly of the International Council of Scientific Unions in London in July 1946. This resolution, which arose out of discussions on research on nuclear energy, affirmed the conviction of the International Council that international security and welfare would be impossible if in any country military secrecy be allowed to dominate scientific discovery or to prevent the frank discussion and open publication of scientific results. Accordingly, the General Assembly, in the name of the men of science of the nations represented, acknowledged in this resolution the duty on the part of scientific workers: (*a*) to maintain a spirit of frankness, honesty, integrity and co-operation and to work for international understanding; (*b*) to promote the development of science in the way most beneficial to mankind and to exert their influence as far as possible to prevent its misuse; (*c*) to serve the community not only by their specialized work but also by assisting so far as they are able the education of the public in the purposes and achievements of science.

The declaration now issued by the Committee on Science and its Social Relations points out that the prominent position held by science in society and the rapid transformation of the world through the application of science carry with them, for scientific workers, special obligations over and above the ordinary duties of citizenship. The Committee lists among these obligations the first two recorded in the resolution from the International Council of Scientific Unions, and adds three others: to examine consciously the meaning and purposes of the work that he or she is performing; when in the service of others to inquire into the purpose for which the work is being done and the moral issues that may be involved; and to assist in the education of the people and government in the purposes and the achievements of science. Furthermore, to fulfil these obligations, the Committee urges that it is necessary to claim certain rights for scientific workers, and especially: (i) freedom of publication and the utmost freedom to discuss one's work with other men of science; (ii) economic security and the right to participate freely in all activities permitted to all citizens; (iii) the possibility of obtaining information about the purposes for which his or her work is being done.

Now the obligations detailed by the General Assembly of the International Council of Scientific Unions are clearly in line with the rights defined in the United Kingdom draft of an International Bill of Human Rights, as well as with American opinion in this field, and are the counterpart of the freedom of speech and publication and information set forth in that draft, though it should be noted that however admirable the sentiments it is not easy in practice to give precise meanings to some of the terms. There may well be acute differences of opinion in interpretation and even sharp dispute. The further obligations and rights detailed in the new declaration from the Committee on Science and Social Relations, however, bristle with such difficulties and require very careful scrutiny before they can be accepted for what they purport to be and held universally valid.

In the first place, when the proposed charter substitutes an over-riding professional loyalty, something in the nature of a Hippocratic oath, for the strong national loyalties of to-day, it is as well to be quite clear as to the consequences. Something of what may arise is indicated by the circumstances in Britain which last spring forced the Government to exclude from a certain range of appointments Communists and others whose particular political loyalties were suspect of over-riding national loyalties. Though there may be a large measure of international agreement on the traditional loyalty of any profession, it is imperative, in a world where international loyalty itself has commonly so little force, that national loyalties should not be disregarded too lightly, however untoward some of their consequences may be.

The framers of this declaration obviously had in mind the increasing use of science for military ends; but they do not appear to have taken sufficient account of the position of the individual scientific worker. It cannot seriously be maintained that the professional organisation of even, say, chemists is sufficiently strong and virile to afford a chemist the support and anchorage anywhere in the world which will enable him in any circumstances to refuse to work for military ends. If, say, under a dictatorship, persecution or other means compels him to do so, while in democracies and elsewhere he refuses to do so, the practical result might be the overthrow of the democracies and probably of science with them.

Viewed from this angle and without other measures, the charter might well be of no more value than the Kellogg Pact. The work of most men of science, however, is not primarily or even secondarily connected with preparations for war. Most of them are engaged in some form or other of work in industry, and the terms in which the obligations and rights of the scientific worker are set forth by the Committee on Science and Social Relations seem to take very imperfect account of that fact. The freedom of publication and freedom to discuss his work with other men of science must in industry be subject to some limitations. In practice, industry in Britain does pursue an increasingly liberal policy towards publication of research results; but while, for example, the practice of patenting remains, there are clearly other considerations, and the responsibility for decision as to publication and public discussion must remain one for management. Indeed, the claim that the man of science should be fully informed about the purposes for which his work is required makes it more essential from the point of view of industry that the management should retain the responsibility for decision as to publication. The whole trend of thought and policy is towards giving all workers more information as to the reasons for the work as the best means of securing wholehearted co-operation, and the Barlow Report on Scientific Staff and other reports have emphasized the importance of taking scientific and technical staff into the full confidence of the management. The wisdom of that practice was demonstrated repeatedly during the War in the case of what is commonly described as 'operational research'.

That, however, is reciprocal. The confidence of management in the scientific worker must be met by a readiness on the part of the scientific worker to respect that confidence, and by the understanding that there are times when it is not in the public interest to disclose information acquired in confidence. The disclosure of confidential information cannot be claimed as a right, above all in the face of a formula which almost enjoins a scientific worker so minded to pry into the whys and wherefores of what he is doing. While very few would be likely to abuse such a right, no commercial firm could be expected to tolerate the absurd position which might arise, and any charter intended for universal acceptance must have regard to the conditions of every life in which the rights and responsibilities it adumbrates will be exercised.

What sometimes appears to have escaped the minds of those responsible for drafting the present charter is that freedom and rights are contingent. Seldom, if ever, can they be regarded as absolute. That much was implicit in the United Kingdom draft of an International Bill of Human Rights, and discussions at Geneva and elsewhere have indicated not only the difficulty of giving precise definition to rights which could be legally enforceable, but also the value of a declaration as opposed to a legally binding international agreement. A declaration which, without being Utopian, represented the practice of the most advanced countries might be accepted sincerely as a standard, and may well prove to be the most satisfactory solution to the problem so far as it touches men of science.

Much searching and honest thought will have to be given to the problem if a set of formulæ is to be derived which can command universal assent and respect without being too vague to be of value. The present declaration cannot be regarded as more than a contribution to the discussion, if indeed it were ever intended as more. At least it deserves to be examined and criticized constructively by those more familiar with the problems of industry and competent to assess the position of the industrial scientific worker than the members of the Committee on Science and its Social Relations itself would appear to be. The ethical and moral basis of world order and international co-operation will not be achieved without an intellectual effort at least comparable with that through which the discipline and tradition of any profession have been developed.

NATURE AND COGNITION

Natur und Erkenntnis

Die Welt in der Konstruktion des heutigen Physikers. Von Prof. Arthur March. Pp. viii + 239. (Wien: Springer-Verlag, 1948.) 21*s*.

THE author, who is well known as one of the pioneers in the field of quantum theory, has in this book made the attempt to present the fundamental ideas of modern physics without the use of mathematics in such a way that an intelligent reader could really understand their implications. For this purpose it is of paramount importance to analyse in everyday language the hidden meaning of the mathematical formalism. This is a tremendous task, and it seems doubtful if readers who have no knowledge of higher mathematics can in this way be made to understand what is meant by infinite matrices, eigenvectors, invariants, etc. A few chapters are devoted to the discussion of the nature of particles and of waves, and the author makes every effort to explain the apparent contradiction between the two aspects of one and the same phenomenon. In spite of this, I think, the average reader will sometimes feel rather giddy from the exertion of having constantly to change his angle of view during complicated discussions, like the one on the meson theory of nuclear forces.

The most important part of the book is that in which the author attempts to explain, in a generally intelligible way, the idea of a fundamental smallest length in Nature, and in his foreword he confesses that he has written the book mainly for this purpose. As the Planck constant h restricts the detailed description of events and reduces them to 'elementary acts', similarly the existence of a smallest length l_0 restricts the measurement of space (and consequently of time), and puts a limit to the analysis of space and time relations. It is shown how by the introduction of this new principle certain serious difficulties concerning the interaction of fields and particles can be removed satisfactorily.

The author also tries to make the reader acquainted with the philosophical implications of the quantum theory. His own attitude as that of a 'phenomenologist' is to object to the use of 'not measurable' quantities in a physical theory, although he raises no objections against the use of continuous coordinates (which are not measurable according to the principle of a smallest length) or against the use of complex wave functions (which are not 'observable' quantities in quantum mechanics). He maintains that present-day quantum theory already provides the fullest possible description of the physical world and that we simply have to accept as a not further explicable fact that the individual phenomena are not subject to the law of causation, but that it nevertheless applies to mass phenomena. This sounds rather like Du Bois Reymond's defeatist "ignorabimus", and the majority of scientific men will prefer Hilbert's famous motto: "We must know and we shall know".

The book is not intended to describe the historical development of the ideas to which it is devoted, and so the names of the discoverers of the most important facts and ideas are only casually mentioned. But certain omissions are to be regretted; although, for example, the statistical interpretation of quantum mechanics forms one of the main fundamentals of the author's discourse the name of the originator of this idea, Max Born, is not even mentioned. The inclusion in the book of a short historical review with names and data and references to original literature, and an index of subjects and authors would certainly increase its value.

The book makes very enjoyable reading because of the charming way in which the subject is presented, although it was written under most distressing external conditions. It is to be hoped that it will be translated into English so that it may become available to a broader public in this and other countries.

R. FÜRTH

A REVIEW OF TRACER WORK

Dix ans d'application de la radioactivité artificielle

By Dr. Pierre Süe. Pp. 258. (Société d'Éditions Scientifique, Paris, 1948.) 675 francs.

THE Scientific Information Conference held by the Royal Society during June 21–July 2 has directed the attention of wider circles to the importance of the work of abstractors and reviewers for the progress of science. One of the Conference's recommendations was that "senior scientists should regard the provision of reviews as an important ancillary to the pursuit of new knowledge". It is obvious that the need for such help is greatest in rapidly expanding branches of science, as, for example, radioactivity.

That scientific workers in other countries are of the same opinion is shown by the survey on the use of radioactive tracers just published in Paris. The author is Dr. P. Süe, research director in Prof. Joliot's Laboratoire de Chimie Nucléaire. It represents a practically complete compilation of the relevant literature up to September 1947. The essential part is a chapter in which the material is arranged according to the subject of the researches; if the title of a paper does not seem sufficient, a brief summary of its content is added. Only the author of the paper and a number are given in these tables; the bibliographic reference is to be found in the succeeding alphabetic list of author names. If there are several authors, only the first one is mentioned, which makes it, unfortunately, impossible to trace in this way the other authors whose existence is indicated by an "et al." only. A third list which will frequently prove helpful, arranges the papers according to the radio-elements used.

The book begins with a survey of all radioactive nuclides, based largely on the well-known tables published by Prof. G. T. Seaborg in 1944. The fact that the author found it advisable to reproduce, for the benefit of his readers, so much published material shows very clearly the present weakness of our arrangements for the distribution of scientific information; for the re-setting of such complicated tables is an unpleasant task where the danger of misprints can only be avoided by very time-consuming proof reading. However, the printers and correctors seem to have been very successful, more so here than in other parts of the book; but for the errors which do occur in this first edition, certainly no excuse is needed. One regrets that, besides misprints, different types of lettering have sometimes been used by the printer without any apparent reason, and that there is no clear system in abbreviating the titles of the scientific journals, one and the same appearing under very varied contracted forms. It would no doubt have been useful to add a list of the abbreviations used, especially as some of the rarer ones can scarcely be interpreted by the average reader, and the understanding of others is made more difficult by printers' errors.

So long as the compilation of such reviews remains the arduous task of busy research workers they will always have to choose between the two evils: of allowing a number of inconsistencies and errors to remain, or to delay publication with the risk that some of the material will already be out of date when the book appears; the only way out of this dilemma seems to be the preparation of such reviews by permanent staffs of professionals and, if possible, in an international organisation. Pending that, the very comprehensive and well-arranged bibliography given to us by Dr. Süe will be found most useful by all laboratories working on radioactive tracers. Nothing equivalent seems to exist yet in the Anglo-American literature, although the bibliography contained in Appendix 5 of the Fourth Semiannual Report of the U.S. Atomic Energy Commission, which lists all papers on isotope utilization that have recently come to the attention of its Isotopes Division, is similar in arrangement. F. A. PANETH

LOW TEMPERATURE PHYSICS

Low Temperature Physics

By Dr. L. C. Jackson. (Methuen's Monographs on Physical Subjects.) Revised second edition. Pp. vii + 130. (London: Methuen and Co., Ltd., 1948.) 6*s.* net.

THE great attraction of low temperature physics as a field of research is that so many of the phenomena still lack any fundamental theory, so that the outcome of any new experiment is rarely a foregone conclusion. The outstanding phenomena at present requiring something deeper than 'phenomenological' theories are superconductivity and the properties of liquid helium, and other as yet unsuspected phenomena may come to light when the new range of low temperatures below 1° K. is properly exploited. The interest of these problems was beginning to be more widely recognized just before the War, and with the resumption of scientific work after the War there has been a great expansion, particularly in the United States, of the facilities necessary for research at temperatures within a few degrees of the absolute zero.

The appearance of a second edition of Dr. Jackson's excellent monograph is thus particularly timely, both because of this increased interest and of the considerable advances made since the first edition appeared in 1934. Dr. Jackson, who was a pupil of Kamerlingh Onnes at Leyden some twenty-five years ago and is at present in charge of cryogenic work at Bristol, writes with the authority of first-hand experience. The treatment (which is essentially the same as in the first edition, but brought up to date) combines very successfully an account of the general principles of each topic discussed with just sufficient practical detail and numerical data to make the description come alive; theoretical results are not usually derived in detail but enough is said to give a qualitative idea of where they come from, and references to more detailed treatments are indicated. In such a short book it is impossible to cover more than a selection of topics, and a wise choice has been made both of subjects which are of interest as topical problems and those needed as a background to appreciate the significance of the latest work. After two introductory chapters on the production and measurement of low temperatures, the main headings are the properties of helium, specific heats in general, electrical conductivity (including superconductivity) and magnetism. Not only may the book be warmly recommended as an excellent introduction for the final honours student or the intending research student, but it may also be read with benefit as a well-balanced survey by those already working in the field. D. SHOENBERG

AMERICAN WAR-TIME CONTRIBUTIONS TO STATISTICAL METHOD

Selected Techniques of Statistical Analysis for Scientific and Industrial Research and Production and Management Engineering

By the Statistical Research Group, Columbia University. Edited by Churchill Eisenhart, Millard W. Hastay and W. Allen Wallis. Pp. xiv + 473. (New York and London: McGraw-Hill Book Co., Inc., 1947.) 36*s.*

IN the United States, as in Great Britain, the value of statistical method and technique became especially recognized during the War. This was an inevitable outcome of need, but is perhaps also some tribute to the contributions of the comparatively few statistical workers. The Statistical Research Group of Columbia University worked for the Applied Mathematics Panel, Office of Scientific Research and Development. One of its major contributions to technique was sequential analysis, the subject of an independent monograph recently prepared by its principal creator, A. Wald. The editors of the volume under review had the rather difficult task of assembling other much more miscellaneous work, which arose as "almost a by-product of the responsible and co-operative handling of practical military, scientific, engineering, and production problems".

They have done this with a series of more or less self-contained and independently written chapters by various authors. These have been arranged in three parts: the first, on "Industrial Statistics", including two long chapters by W. Allen Wallis on the "Use of Variables in Acceptance Inspection for Percent Defective" and by Harold Hotelling on "Multivariate Quality Control, Illustrated by the Air Testing of Sample Bombsights"; the second, on "Planning Experiments"; and the third on "Techniques and Tables". Unfortunately this arrangement is at times extremely arbitrary; for example, it is not very obvious why two technical investigations by Churchill Eisenhart on the "Effects of Rounding or Grouping Data" and the "Inverse Sine Transformation of Proportions" should be allocated to different parts. The references to sequential analysis seem unsatisfactory, an elementary account by Wallis concluding the volume, whereas the first chapter includes a sequential problem of strictly more complex type.

Such limitations cannot, however, be entirely avoided in an *ad hoc* collection of this kind. Provided it is not regarded as a text-book, but as a record of miscellaneous work, it serves two purposes: (1) as a reference book (with some useful tables and charts, and an almost too exhaustive index); (2) as an indication of the potential value of such techniques, in peace as well as in war, to its intended readers—"scientists, engineers, managers, and statisticians". One may wonder how much the middle two, at least, of these groups like the presentation, and might not have preferred the technical notes concluding some of the chapters to have spread to cover most of the exposition, leaving a simple introduction in each case to summarize the article. This would, however, have meant still more editing to meet a rather speculative requirement, for many engineers and industrialists have by now recognized the value of statistical techniques and do not need to be so spoon-fed. Perhaps before long even the claim in the preface that "the chemical, physical and engineering sciences are, on the whole, distinctly backward in the statistical planning of experiments and the analysis of empirical data, at least by comparison with the social, biological, and agricultural sciences" (compare the war-time success of biologists in the kindred subject of operational research) will no longer be tenable.

M. S. Bartlett

FRENCH PALÆOLITHIC ART

Le centre préhistorique de Ganties-Montespan (Haute-Garonne)

Par Félix Trombe et Gabriel Dubuc. (Archives de l'Institut de Paléontologie humaine, Mémoire 22.) Pp. 128. (Paris: Masson et Cie., 1947.) 1,200 francs.

This *Mémoire* of the Archives de l'Institut de Paléontologie humaine deals with palæolithic art discovered in the side galleries of an underground river by Monsieur Casteret in 1922. Near the little village of Ganties in the region of Saint Gaudens to the south of the River Garonne there occurs a sort of natural reservoir at the base of a low chain of limestone hills which separate Ganties from another little village, Montespan. During æons of time the waters which accumulate in the 'reservoir' have filtered through the limestone hills, eventually forming an underground river which comes out at Montespan to form a small tributary of the Garonne.

During the exceptionally dry summer of 1881 the water in the 'reservoir' fell so low that the underground river was for the first time disclosed and partially explored. Since then the water always stood too high and no further exploration was possible until 1912, when an artificial entrance was made. In 1922, however, Monsieur Casteret dived under a siphon at the Montespan exit and started to explore the underground river from that end. In some dry side galleries he came upon examples of palæolithic art—engravings, clay tracings and modelling, etc.—and these have now been made more accessible. In the vicinity are some rock-shelter 'homes', where traces of upper palæolithic man's handiwork, including some examples of the 'home' art, have been found.

Monsieur Casteret found no strikingly beautiful works of art, nor do paintings occur; no lovely painted bisons like those in the cave of Niaux, which is not so very far away, were discovered, but the finds are none the less of considerable interest. Some of the engravings, judging by their style, were probably the work of Aurignacian man, as too were most of the tracings in clay which recall closely those of the cave of La Clotilde in northern Spain. The rest of the engravings would seem to be early Magdalenian in date. The discovery of the body of a cave bear modelled in clay raises some interesting problems. It had no head and it would seem may have been used as a stand over which the skin and head of a real bear could be thrown. This appears to have been used as a target, and many of the arrows, penetrating the skin, have left marks in the clay underneath.

The volume gives a full account of the site and the history of the discovery, and the prehistoric art is fully described and illustrated. As is true for almost all the *Mémoires* of the Archives de l'Institut de Paléontologie humaine, it is indispensable for the student of prehistory, and this is especially true if his interests are particularly focused on the upper palæolithic art.

M. C. Burkitt

BRITISH TRADE UNIONISM

British Trade Unionism

Six Studies by P.E.P. Pp. vii+184. (London: P.E.P., 1948.) 15*s.* net.

In several broadsheets, notably that on "Output and the Worker", in April 1945, "Inside the Unions", in May 1946, and "Framework of Collective Bargaining", Political and Economic Planning has already examined problems confronting the trade unions and their position in a society organised for full employment. The present report carries that examination a stage further. It is primarily a factual study of British trade unions and their place in industrial relations, and is intended rather to provide a firm foundation for the future study of policy than to indicate solutions to the numerous vital problems which it brings into the light of public discussion. The wider interest of the study, moreover, is derived from the relation of the inquiry and the discussion it seeks to stimulate to the larger problem of active democracy on which *Planning* is simultaneously engaged.

The six studies comprising the present volume cover first the structure of the trade unions, their size, hierarchy and the characteristics of union membership at the three levels distinguished in the earlier broadsheet: the national officials, the active branch membership and the rank and file. In emphasizing the dynamic human relationships, this study makes a welcome contribution to a wider and more sympathetic understanding of the unions on the part of the general public. This contribution is the more important as much of the second study is perforce purely descriptive, and the outline it gives of the formal machinery of negotiation loses something of this vital human touch because it is compressed to a mere sketch. The balance, it is true, is redressed by a concluding section which stresses the underlying similarities of the main types of machinery and the effect upon them of the increasing concern of government with wage levels.

In the third study the part played by the trade unions in the determination of wages is brought out, the factors determining wages are indicated and some of the implications of the social redistribution of income and of a national wages policy are briefly reviewed. The latter part of this study covers such other subjects of negotiation as hours and overtime, demarcation of crafts, apprenticeship and the like. The fourth study, entitled "The General Staff of Labour", describes the work of the General Council of the Trades Union Congress, the evolution of a central trade union policy and the relations of the trade union movement with the Labour party, with employers' organisations, the Government and, more briefly, with international bodies.

Valuable as are these studies in removing misconceptions regarding trade unions, the fifth study may prove to be the most important from that point of view. In this study of relations on the job, *Planning* gives a clear account of the position and functions of the shop steward that can scarcely fail to assist constructive thought on the whole question of organisation at the workshop level and the development of joint consultation, whether from the point of view of production or for other purposes. Moreover, the concluding section on psychological and other factors affecting relations indicates the importance of a number of the problems which the Panel on Human Factors of the Committee on Industrial Productivity is already examining.

For these factual studies, that Committee may well be grateful to Political and Economic Planning; but the last study, of trade unions in post-war Britain, which surveys trade unionism in relation to economic policy, full employment, nationalized industries and other major questions of the day is undoubtedly that which will have the widest appeal. This brilliant but sympathetic analysis should challenge constructive thinking within and without the unions, and indicates where the real psychological obstacles to high productivity and industrial democracy lie. For this study alone Political and Economic Planning has earned the thanks of all who are seeking the economic recovery of Britain, and no better approach could well be made to that essential task of education and the improvement of public relations than this concise and impartial assessment of opportunities, responsibilities and shortcomings.

CLINICAL ENDOCRINOLOGY

Clinical Endocrinology and Constitutional Medicine

By Dr. A. P. Cawadias. Pp. xii + 368 + 10 plates. (London: Frederick Muller, Ltd., 1947.) 42*s.* net.

THIS is an interesting and useful book. The author has made an extensive survey of the clinical conditions that can be attributed to malfunctioning of the endocrine organs, and has based his observations upon a reasoned picture of the "physiology and pathology of the neuro-endocrine systems". The introductory part of the book, which deals with this basic information, begins with a discussion of the concept of hormonal action and of the present trend for endocrinology to find its main links in the general field of metabolism. The rest of the introductory section is devoted to a general description of the "neuro-endocrine systems" of which the derivatives of the branchial pouches are part; of the neuro-metabolic systems based upon the gonads and the adrenals; and of those based upon the pituitary and pineal. By "system" Dr. Cawadias does not mean that a given endocrine substance is responsible for a series of changes that are part of a pattern of wider change which is influenced by the whole endocrine system. The term is used to emphasize the point that the endocrine organs work in a system with such neural structures as the hypothalamus, and that the latter in turn may be influenced by psychogenic factors. When he talks, for example, of the thyro-hormone system as being part of the neuro-endocrine system, he has in mind that cortical influences can affect the hypothalamus; the hypothalamus the anterior lobe of the pituitary; and the anterior lobe the thyroid; and that the whole thyroid system can be activated from any of these centres.

After its introductory section the book deals in turn with clinical disorders that relate to the thyroid, parathyroid and thymus group of glands; to those that relate to the gonadal adrenal group; to those of the pituitary pineal group; and to those of the pancreas liver group. The description of each disorder begins with a brief definition of the condition it discusses, and then surveys its etiology and physio-pathology, its signs and diagnosis, and its treatment.

The book is well written, and contains numerous interesting references to the older literature. References to recent advances in experimental endocrinology are, however, somewhat unnecessarily restricted. The illustrations are reproductions of drawings, and may not be to the taste of all readers.

NATURE CALENDAR

The Course of Nature

Through the Year from the Pages of *The Times*. Pp. 336. (London: Hodder and Stoughton, Ltd., 1948.) 10*s.* 6*d.* net.

"THROUGH the Year from the Pages of *The Times*" is the sub-title of "The Course of Nature" by W. Kay Robinson, well known as a sound field naturalist and an able writer, with a pen in the true Gilbert White tradition. He speaks of the changing seasons, the happenings of the passing days and reviews the pageant of the year in two weekly commentaries.

Beginning with "New Year Bird Songs" and the music of the great tit, "who seldom fails to ring his bell before this month is one week old", Mr. Robinson journeys interestingly onwards through the months to finish at Christmastide with the great tit once more trying his voice. On the way the author has much to write about; for example, one of his January notes deals with the "grey squirrel's New Year Celebrations". Commenting on the activity of the grey squirrel during the hardest of weather he goes on to say: "As one passes through the oakwoods one hears, first, a 'huff, huff, huff', followed by the queer sound which, beginning like a jay's harsh screeching, ends like a kitten's mew, and is possibly a love-call, possibly a challenge, or perhaps just means the squirrel is very much annoyed". The reviewer believes this cry to be a love-song, an idea supported by the date of birth of the young, many litters being born in February.

From squirrels to moles, from moles to waxwings, and then to redwings, flits the author's pen, commenting with regard to the last named on their inability to stand prolonged hard weather. "Though they come to us from colder regions to the north, the redwings seem constitutionally less fitted to withstand the rigours of winter than our own thrushes and blackbirds, and once the hedgerows have been stripped of berries they are in a bad way." But to appreciate this excellent survey of Nature through the seasons it must be read chapter by chapter, for it is full of good matter and that whether the month be January or June.

FRANCES PITT

Thomas Jefferson Among the Arts

An Essay in Early American Esthetics. By Eleanor Davidson Berman. Pp. xviii+305+20 plates. (New York: Philosophical Library, Inc., 1947.) 3.75 dollars.

IN view of the distinguished position occupied by the United States to-day, one is perhaps apt to forget what strife and labour went into the development of the young republic in the period of its third president. Those were times when 'art' was too expensive, yet in all its forms, so much to be desired. Thus we find Jefferson the revolutionary, workman, writer, thinker, toiling ever and anon to establish culture, both abstract and material, in his youthful America. To him there was no difference between 'pure' and 'applied' (whether art or science); all was for the benefit of mankind, and the pursuit of the good. Naturally, this led to some strong likes and dislikes, short shrift for Plato and Samuel Johnson, to mention but two.

Love of contrast is characteristic; formal Palladian architecture, surrounded by 'serpentine' gardens, as if to say "Oh Western Wind, blow soft and kind" upon the exceedingly solid and uncompromising stone buildings he admired and advocated. The author of the Declaration of Independence is entitled to such light and shade in his dealings with contemporary events.

The book itself is a careful document on the whole, somewhat disfigured by a fantastic misprint ("Nogarth" for Hogarth) on Plate 10, but pleasant to read and valuable for its references. It depicts Jefferson the man, very much a son of the *Enlightenment*, the master-craftsman of his age. F. I. G. RAWLINS

Magnetic Materials

By Dr. F. Brailsford. (Methuen's Monographs on Physical Subjects.) Pp. ix+156. (London: Methuen and Co., Ltd., 1948.) 6*s*. net.

THE appearance of this excellent monograph is opportune. During the past decade there have been immense advances in the quality of magnetic materials, both for cores of special transformers, electro-magnets, and particularly for permanent magnets, leading to greatly improved instruments, methods of measurement, and components generally. In one field alone, that of recording sounds on wire or powder, the whole process of magnetization had to be re-investigated, with a resulting new idea in the selection of material, leading to the sudden improvements which are about to be made commercial.

The author gives the clues to these reconsiderations, by relating the observed phenomena to defects in the shells of electrons and the rigidity or otherwise of the crystal lattice. Theory has indicated the lines of advance, and, in the laboratory, there are already 'better' (that is, better for special purposes) materials which are impracticable only by reason of cost.

The main purpose is, however, to give a complete story of the theory behind the materials, and this is offered with the utmost clarity. L. E. C. H.

Fahrten in Island

Von Rudolf Jonas. Pp. 198 + 83 plates. (Wien: L. W. Siedel und Sohn, 1948.) 3.50 dollars.

IN 1935 a party of Austrian scientists under Dr. R. Jonas and Prof. F. Nusser made a crossing of Vatnajökull, Iceland. The personnel was organised by the Austrian Students' Travel Association. The participation of the National Union of Students in England was proposed but could not be arranged in time. Some glaciological research was completed and part of the northern margin of the ice was mapped. This book is concerned mainly with that expedition and contains some good accounts of Icelandic scenery. The nunatak known as Mount Paul was rediscovered and fixed, and the crater of Sviagigur was explored. The numerous illustrations are excellent and the maps are adequate.

Cosmic Rays and Nuclear Physics

By Prof. L. Jánossy. (Frontiers of Science Series.) Pp. xiv + 186. (London: Pilot Press, Ltd., 1948.) 9*s*. 6*d*. net.

THIS is a more popular version of the book on cosmic rays by the same author which was reviewed in *Nature* of May 22, p. 785, 1948. The subjects treated, and their ordering, are much the same as in that book, though less detail is given. Theory is, in the main, omitted; but the most important formulæ are quoted, and a valiant effort is made to explain how they are derived. The book, like the earlier one, aims at comprehensiveness; but is not too well arranged.

The Frontiers of Science Series, of which the book forms part, aims at serving the non-specialist public who have outgrown the 'told to the children' approach. But this book can appeal only to a restricted public; for example, it introduces without explanation technical terms like azimuth, pentode, radius of curvature, electron volt, rest mass and energy, relativistic velocity, etc., and the fact that relativistic ideas are in principle explained later would scarcely compensate for the confusion which their first mention would evoke. The book could be read with profit by a man who has taken a science degree with physics as at least a subsidiary part, or by a brilliant schoolboy, and can be recommended to people like these. But it is not a popular book in anything like the usually accepted sense; it is a beginner's research manual, characterized by the researcher's inclusion of much detail, many references, and minor qualifications of general statements. It can be warmly recommended to people of the right sort; but one cannot agree that it achieves the avowed aim of the Series in that it "requires no previous specialized knowledge".

T. G. COWLING

Adventures with a Naturalist

By Roy Bedichek. Pp. 258. (London: Victor Gollancz, Ltd., 1948.) 12*s*. 6*d*. net.

THE scene of this book is in Texas, and its theme is the effect of the white man on animal and plant life. The author begins: "I have been looking over a two-hundred-acre plot of fenced land and trying to compare the life it now supports with that which it had been supporting for thousands of years when the first white man occupied it a hundred years ago". Although Mr. Roy Bedichek entitles his work, "Adventures with a Naturalist", although the title is excellent and he takes us on many delightful adventures observing a variety of birds, mammals and plants, we ever come back to the distressing effect of the white man, his agriculture and other activities, on the indigenous fauna and flora, an all too sad effect not limited to the American continent, but associated with him the world over. This is an interesting and pleasant book, despite its pre-occupation with a mournful theme, and covers a wide field of Nature and country life.

FRANCES PITT

GENETICS OF CANCER

ONE of the many problems arising from the study of tumour transplantation and of chemical carcinogens is the variable degree of susceptibility to cancer shown by different animal strains. This phenomenon has focused attention upon the hereditary basis of cancer, and a great wealth of experimental data has now accrued. The aim of the recent symposium on the Genetics of Cancer held in London during June 24–25, and sponsored jointly by the Genetical Society of Great Britain and by the British Empire Cancer Campaign, was to survey this field and direct attention to the significance of such recent discoveries in genetics as, for example, the role of cytoplasmic particles in heredity, differentiation and disease.

The symposium could cover only certain selected groups of problems, and the papers presented centred around three main topics: (1) the inheritance of tumours in animals, (2) the genetical aspects of virus-induced and chemically induced tumours, and (3) the inheritance of cancer in man.

(1) The genetical basis of tumour transplantation in mice was discussed by Dr. P. A. Gorer (London), according to whom tumour-transplantability depends on a number of genes, some of which determine the production of specific antigens, identified as the 'histo-compatibility' antigens. The high rate of polymorphism observed in various strains of mice by serological analysis Dr. Gorer attributed to the high rate of mutation of these genes, a fact which would also explain the frequent failures of tumour transplantation.

The genetical basis of tumour production and that of its transmission may be quite different in complexity, as was shown by Dr. G. Högreffe (Copenhagen). Transmission of leukæmia in the 'Aka' strain of mice seems to be due to a single Mendelian factor inherited as an autosomal dominant. From transplantation experiments, however, it became apparent that the genetical basis of tumour production is much more complex.

The genetical factors involved usually operate through various intermediate agencies such as hormones. When these intermediaries are analysed in isolation the primary biological factors of tumour production may be completely obscured, and this feature was well demonstrated by Dr. R. Korteweg (Amsterdam), who dealt with the influence of œstrogenic substances on tumour susceptibility. From his data it appears that the high incidence of mammary tumours in certain strains of mice is correlated with excessive secretion of œstrogens, and that at least part of the genetically determined disposition is caused by over-production of gonadotrophic hormone.

The complexity of the hereditary basis of tumour production was further emphasized by Dr. L. Dmochowski (Leeds), who analysed the interaction of mammary tumour-inducing 'milk-factor' and genetic constitution in the development of breast-tumours in certain high- and low-breast cancer strains of mice. Dr. Dmochowski arrived at the conclusion that there are two distinct sets of genetic factors, one controlling the susceptibility of breast tissue cells to the milk factor, the other controlling the propagation of the milk factor itself. The influence of hereditary factors on the production and transmission of the milk-agent was again made clear by Dr. W. E. Heston (Bethesda, U.S.A.), whose experiments have shown that the milk-agent is not itself active, but rather prepares the substrate, that is, the mammary glands, for the initiation and mediation of tumour production by genetic factors. Dr. Heston's analysis suggests that mammary tumours may be induced in the absence of the milk-agent through the provision or construction of certain genetic and environmental patterns.

(2) The alteration of the genetic structure of cells by chemical means is a subject of relatively late development in genetics, and throws light on the possible mechanisms underlying not only 'spontaneous' or naturally occurring mutations, but chemical carcinogenesis as well. Dr. M. Demerec (Cold Spring Harbor, U.S.A.) presented evidence that when *Drosophila* males were exposed to aerosols of seven carcinogens (four hydrocarbons, three azo-compounds) six such compounds were found to be mutagenic, while of nine non-carcinogens (five hydrocarbons, four azo-compounds) only two were mutagens. Somewhat similar results were obtained by Dr. J. G. Carr (London), and it would seem that specific chemical compounds can certainly induce permanent alteration in the hereditary structure of cells, whether germ-cells or somatic cells. Prof. L. C. Strong (Yale University) described a multiplicity of biological effects obtained by injection of methylcholanthrene into a series of mice, over many generations. Some of these effects are definite point mutations, some are non-genetic, while others are possibly induced by inhibition of embryonic morphogenesis at critical periods.

Data were also obtained by Demerec, in experiments with aerosols of carcinogens on *Drosophila*, indicating that there is a semi-dominant gene which determines whether or not an individual will be sensitive to the chemical induction of genetic change. There is no doubt that experimental evidence of such a diversification of gene-controlled susceptibility to chemical effects is of the greatest significance in relation to the causation of cancer. The work of Dr. A. W. Greenwood (Edinburgh) on the inheritance of susceptibility and resistance to the virus-induced Rous sarcoma showed the existence of such genetically controlled differences in fowls.

The work of Sonneborn and others has established the existence of special cytoplasmic particles which also play a part in heredity. Prof. P. B. Medawar (Birmingham), through experiments on colour transformation in guinea pigs' skin, has provided what may be another example of the particulate basis of somatic cellular heredity, and has indicated that these determining particles can behave 'infectively' towards other cells. Dr. C. D. Darlington (London) further suggested that the origin of some types of cancer can be ascribed to mutation in such cytoplasmic determinants. By analysing the relationship between carcinogens and viruses and its bearing on the origin of cancer, Prof. A. Haddow (London) concluded that carcinogens may induce change in a cytoplasmic particle analogous with a virus, and that the change may be brought about directly or through a primary change induced in nuclear genes. In work carried out by Prof. R. D. Passey and his collaborators at Leeds, particles of 200–350 A. in diameter were identified by the electron microscope in the milk and tumours of high-cancer strain mice, and the biological test of these particles, for tumour-inducing activity, is awaited with special interest.

(3) In the session dealing with the inheritance of cancer in man, the symposium was presented with a general survey of the problem by Prof. T. Kemp (Copenhagen). The investigations carried out in Denmark suggest a genetical basis for predisposition to cancer, involving several genes, and furthermore that the localization, pathological features, rate of development and the time of onset of tumours may be similarly controlled. Since environmental factors also play a part in the development of particular kinds of cancer, any analysis of the heredity of cancer in man inevitably meets great difficulties. In order to compare the incidence of cancer in families with that in the total population, a critical collection of control material is required, and the difficulty of obtaining such material was stressed by several participants in the symposium. To a certain degree the problem has been solved by Prof. L. S. Penrose (London) and his collaborators, using the Registrar-General's statistics for calculating the expected proportion of breast cancer and cancer deaths among relatives dying at all ages and at most periods of the immediate past: the expected death- and incidence-rates for relatives can thus be compared with the observed figures. Prof. Penrose analysed the family-histories of 510 cases of mammary cancer by this method and found that the proportion of deaths due to mammary cancer in the patients' relatives was significantly increased, the rates for other types of malignancy remaining unchanged. Similar conclusions were arrived at by Prof. D. Smithers (London) from the study of family-histories of 459 patients with cancer of the breast. Prof. Penrose concluded that a specific genetical agent is responsible for mammary cancer in man. Evidence concerning the nature of this agent was obtained from studying incidence in paternal and maternal relatives, laterality, age of onset and history of breast feeding in the patient's own infancy, from which Prof. Penrose found some indication that the specific agent might be cytoplasmic but probably not transmitted through the milk.

The studies carried out by the Danish Cancer Registry on twins, under the direction of J. Clemmesen, were presented by Dr. Th. Busk (Copenhagen). From these it seems there is a greater tendency to higher incidence of cancer among partners of identical twins afflicted with cancer than among partners of fraternal twins with cancer, and also a clear tendency for tumours in identical pairs to affect corresponding organs in both partners, whereas this is not the case among fraternal twins. Though the investigation covered about 30,000 cancer patients, only 187 twins with cancer were found suitable for analysis.

It is hoped that the investigations reported at the symposium will direct attention to the importance of recording comprehensive family histories. The need for collaboration in these matters between physicians, geneticists and statisticians was illustrated in a paper by Dr. P. C. Koller (London), who presented two family-histories of xeroderma pigmentosum, one showing an unusually mild manifestation of the disease. The distribution of this condition among the two sexes and the unusual pathological features throw further light on its genetical basis and suggest that we may need to modify Haldane's concept of partial sex-linkage in respect of this particular disease.

The proceedings of the symposium will later be published in the *British Journal of Cancer*.

P. C. Koller

THE *Rh* FACTOR OF BLOOD

During the summer meeting of the British Medical Association in Cambridge, the pathological section held a discussion on "Recent Advances in our Knowledge of the *Rh* Factor". Only the opening speaker kept strictly to this title, the other two invited speakers reading papers on closely related topics; therefore each contribution will be described separately.

Prof. D. F. Cappell, of Glasgow, first briefly described the history of the discovery of the *Rh* factor. Landsteiner and Wiener, seeking to extend knowledge of the complexities of the agglutinogen *M* in man, immunized guinea pigs with the blood of rhesus monkeys. Surprisingly, they found that the resulting anti-rhesus serum agglutinated 85 per cent of human bloods and that the agglutinogen '*Rh*' so defined was unconnected with *M*. Almost immediately afterwards Wiener and Peters demonstrated the clinical importance of this antigen by showing that, in each of four cases where repeated blood transfusions had been followed by hæmolytic reactions, the cause lay in the sensitization of the patient to the *Rh* antigen. Levine and his co-workers then showed that the dreaded intra-group transfusions of women in the puerperium were also the result of iso-immunization to *Rh*, and they directed attention to the almost invariable association of such reactions with death of the fœtus or the occurrence of icterus gravis neonatorum. They produced striking statistical evidence that in these cases the *Rh* negative mother became sensitized during pregnancy to the *Rh* antigen in the blood of her fœtus and formed *Rh* antibodies.

Prof. Cappell suggested that the term *Rh* factor should be reserved for the antigenic component common to man and the rhesus monkey, and the term *Rh* blood group should be used to include the whole complex of antigens which had been shown to occur together in different combinations in man. Prof. Cappell now turned to the work of Prof. R. A. Fisher and emphasized that it was he who had first recognized the pattern behind the complex reactions within the *Rh* groups. Fisher first noted that the reactions of different bloods with two of the four *Rh* sera then discovered were antithetical, and he postulated that the alternative reactions were due to the presence of an antigen *C* in some bloods and of an allelomorph *c* in others. Fisher postulated the existence of two other pairs of allelomorphic antigens, *D* and *d* and *E* and *e*, which determined positive or negative reactions with the two other kinds of sera then known, which he called anti-*D* and anti-*E*. He predicted the discovery of two further antibodies, anti-*d* and anti-*e*, and the correctness of his entire conception was soon demonstrated when these predictions were fulfilled. Fisher's original scheme had had to be extended since Race's discovery of further allelomorphs C^w, C^u and c^v at the *C/c* locus and Stratton's discovery, recently extended by Race, of further allelomorphs at the *D* locus.

Prof. Cappell emphasized the importance of a pure anti-*D* serum for classifying bloods as *Rh* positive or negative. For clinical purposes the important thing was whether a person was *D* positive or negative, for all *D* negative persons could form anti-*D*, and sensitization to *D* was far commoner than sensitization to the other *Rh* antigens. Thus, a person of type *Cde/cde* might at one time have been considered *Rh* positive because of the possession of *C*;

but such a person was just as liable as one of type *cde/cde* to form anti-*D* and should be considered as *Rh* negative.

Iso-immunization of an *Rh* negative mother rarely occurred to a sufficient extent during a first pregnancy to produce hæmolytic disease of the newborn, but the second or subsequent *Rh* positive offspring might be affected. Prof. Cappell had found that the earlier hæmolytic disease occurred in a family, the severer was its form; he interpreted this as indicating a notably greater susceptibility to immunization on the part of some women. One remarkable fact that was now fully established, but the cause of which remained debatable, was the protection against hæmolytic disease afforded by *ABO* group differences between mother and fœtus. Thus, whereas in Scotland in a random sample more belonged to group *O* than to group *A*, in a series of 56 *Rh* negative Scottish women who had formed *Rh* antibodies, it was found that 28 belonged to group *A* and only 18 to group *O*.

Turning finally to the treatment of hæmolytic disease, Prof. Cappell said that one controversial question was whether nervous sequelæ could be prevented by early transfusion of *Rh* negative blood. In his own series of thirty infants treated by transfusion of *Rh* negative blood immediately after birth or within the following twelve hours, all developed normally, both mentally and physically. By contrast, in a series treated in Glasgow between 1934 and 1944, mainly by transfusion of blood of unselected *Rh* type, about 12 per cent showed some residual nervous sequelæ. He was doubtful whether the cerebral damage which results in nuclear jaundice occurred before birth; he suggested that anoxia in the immediate post-natal period, due to difficulty in establishing respiration, might be the cause.

Dr. P. L. Mollison confined his remarks to the diagnosis and treatment of hæmolytic disease of the newborn. At the Medical Research Council's Blood Transfusion Research Unit, Miss M. Cutbush and he had, during the past eighteen months, examined fifty *Rh* positive infants born to mothers whose sera contained *Rh* antibodies. In every case the infant's erythrocytes could be shown, by the direct Coombs' test, to have antibody adsorbed on to their surface. Only three of the fifty infants failed to develop anæmia. Since some infants with a positive direct Coombs' test never developed signs of a hæmolytic anæmia and since others only developed mild signs which did not require treatment, it was necessary to try to form an estimate of the severity of each case. This was best done by examining cord blood. Among the infants with hæmolytic disease whose cord blood they had examined, about two-thirds had a hæmoglobin value below the normal range, that is, less than 15 gm. per cent; almost all had a bilirubin concentration of more than 3·0 mgm. per cent and about three-quarters showed more than 10 nucleated R.B.C. per 100 W.B.C. in the peripheral blood. These three signs of anæmia, hyperbilirubinæmia and erythroblastæmia were fairly well correlated if cord blood was examined and, taken in conjunction with other findings, enabled one to assess the degree of affection.

Dr. Mollison pointed out that hæmolytic disease killed infants at two main stages and the mechanisms were probably separate. Deaths *in utero* or within twelve hours of birth seemed always to be associated with severe anæmia; these infants might display a syndrome similar to that developed by adults with chronic severe anæmia and described by Sharpey-Schafer as the "hyperkinetic phase"; its chief features were: a raised cardiac output, a high pulse-rate and pulse pressure, a high venous pressure and œdema. They had found that a raised venous pressure was a striking feature in severely anæmic infants born alive. The second group of deaths occurred at two to four days; in these cases the infant was profoundly jaundiced and at autopsy kernicterus was a frequent finding. At present the most rational method available for trying to prevent deaths from both of these causes was premature termination of pregnancy followed by an exchange transfusion with *Rh* negative blood.

Exchange transfusion had become a relatively simple procedure since the introduction by Dr. L. K. Diamond of the technique of passing a fine transparent plastic catheter up the umbilical vein; the infant's blood was then withdrawn and replaced by *Rh* negative blood in successive stages. It was an advantage to use a slightly concentrated suspension of erythrocytes so as to leave the infant with a count of approximately 5,000,000 *Rh* negative erythrocytes per c.mm. by the end of the exchange transfusion. It was seldom necessary to have to carry out any further treatment.

Dr. Mollison stated that the overall mortality in the small series he had referred to was 28 per cent. He considered it impossible to make any worth-while comparisons with other series and mentioned the following difficulties: the small size of this and of most other series; recent changes in the diagnostic criteria of the disease; the different prognosis of different forms of the disease and the consequent important effects of selection of cases. As an example he quoted some of their own findings. The first affected infant in a family had a 92 per cent chance of recovery if its mother had never received a transfusion of *Rh* positive blood; but if she had been transfused and was thus more highly sensitized, the infant's chance of survival was only 50 per cent. An undue proportion of transfused mothers in a series of cases would thus greatly increase the mortality. He considered that exchange transfusion should be given a widespread trial because it was a rational treatment and because in practice it had proved to be the most simple and satisfactory method available.

Dr. R. R. A. Coombs described work carried out in the Department of Pathology at Cambridge which had established the occurrence of hæmolytic disease in newborn thoroughbred foals; this disease, like the human one, was due to iso-immunization of the mother during pregnancy against a blood group antigen present in the erythrocytes of her offspring. This work followed on that of Caroli and Bessis, who last year had shown that the icterus of newborn mules was also due to iso-immunization during pregnancy.

Dr. Coombs emphasized that the present investigation had been undertaken by a team. The clinical studies were made by Mr. Parry, scientific officer of the Animal Health Trust, and Messrs. Day and Crowhurst, veterinary surgeons at Newmarket; the hæmatological examinations had been made by Dr. Hoogstraten; the morbid histology had been studied by Dr. Hinde and the serology by Dr. Heard and himself.

Clinically, the foals were normal at birth; thereafter at periods varying from a few hours to five days, they showed progressive weakness, icterus and pallor, accompanied in acute cases by hæmoglobinuria.

The serological investigations had been greatly complicated by a lack of knowledge of the blood groups of horses and by difficulty in obtaining blood samples from the sires of the affected foals. However, they had tested the sera of all the mares, the offspring of which were affected, against the red cells of other mares and of various other available horses. They had found that most of the sera contained high titre saline agglutinins acting on various other horse bloods and all contained blocking antibodies, revealed by the indirect antiglobulin sensitization test. None of the control sera contained more than traces of iso-antibodies.

As in the human disease, the direct anti-globulin sensitization test had proved extremely valuable in making a rapid diagnosis. Hæmolytic disease in newborn foals had to be differentiated from bacterial septicæmia which might also cause jaundice. They had tested six cases of hæmolytic disease, all of which had given strongly positive tests, and two cases of septicæmia, both of which had given negative tests. The reagent they had used was a rabbit anti-horse globulin serum.

The hæmatological picture was one of profound anæmia, with hæmoglobin levels of only 3–4 gm. per 100 ml. Nevertheless, very few reticulocytes and no erythroblasts were seen in the peripheral blood.

One of the most interesting features of the morbid histology was an extension of tubular epithelium into the glomeruli in three cases which had shown hæmoglobinuria; similar changes had been observed in 'traumatic anuria' in man.

Finally, Dr. Coombs mentioned some work which Dr. Heard is conducting. This is an attempt to produce hæmolytic disease in rabbits. There was every reason for hoping that this work would be successful and there was no need to stress the advantage that would result from having a laboratory animal in which the disease could be produced at will. Many problems of hæmolytic disease could only be investigated by experiment and could therefore never be tackled directly in man. P. L. MOLLISON

GENETICAL STRUCTURE OF PLANT POPULATIONS

A SYMPOSIUM on the "Genetical Structure of Plant Populations" was held at the Brighton meeting of the British Association for the Advancement of Science, on September 13, in Section K (Botany), with Col. F. C. Stern in the chair. Dr. W. B. Turrill (Kew), in an opening paper, defined a population, as the term should be used in biology, as the sum total of individuals of a stated kind, in a stated area, at a stated time. The need of careful determination of 'kind' and the desirability of preserving proper voucher specimens where there is the slightest possibility of determinations being called in question were emphasized. The extensive and intensive studies now being completed on numerous populations of a limited number of species of seed-bearing plants of the European flora have revealed an unexpected wealth of variation in structure and behaviour. At Kew and Potterne, investigations combining the methods of modern taxonomy, cytogenetics and ecology are throwing much light upon the make-up of species as population complexes. Attention was directed to the bladder campions (*Silene maritima* and allied species). In these some variations are common, as degrees of indumentum in *S. cucubalus*, others are rare, as long cylindrical calyx in *S. maritima*. Some characters have obvious survival value for definite ecological habitats, such as habit differences between different species or varieties. Spasmodically occurring mutations may be lethal or harmful in various degrees, like 'poor petal' or 'split calyx', whereas other variations appear to be neutral at least in some environments. Some variants have a wide geographical range while others are restricted to very local habitats. Hybridization experiments on a very extensive scale have shown genetic differences for most of the variations; but whereas some characters have a simple genetic basis others can only be explained by the interaction of several genes. Long-isolated populations of relatively small size (as some inland populations of *S. maritima*) may show much less variation than is normally found in more widely spread populations. Parallelism between sea-coast and high-mountain populations of different species is very striking.

Mr. J. L. Crosby (Durham) dealt with intra-population heterogeneity and the breeding range of the individual plant. In the primrose (*Primula vulgaris*), in addition to reciprocally outcrossing plants with 'pin' and 'thrum' flowers, there are, in certain populations in Somerset and the Chilterns, plants with 'long homostylous' flowers which are normally self-fertilized and outcross on to pins. Observation agrees with theoretical conclusions that 'homostyles' are increasing to about 80 per cent, 'pins' are decreasing to about 20 per cent, and 'thrums' are entirely disappearing. Slow at first, change later becomes quite rapid. Considerable heterogeneity between different parts of any one such population may exist. A few yards only may separate groups with constitutions so different that they represent evolutionary stages many generations apart. Such large differences cannot have arisen in one generation by chance from a homogeneous population but must have been initiated at an early stage. One section of the population reached the stage of more rapid change and the difference then became amplified. The change could not, however, even be maintained with free distribution of pollen between the divergent groups, even though 'homostyles' are self-pollinated. The breeding range of the individual primrose must be of the order of a few yards only, and a single population cannot be considered as a continuous interbreeding unit.

Dr. A. J. Bateman (John Innes Institution) considered populations of cultivated plants. He pointed out that the breeding system of the species is of paramount importance in determining the genetical structure of a population. The total range of breeding systems is from complete self-fertilization as in barley to complete cross-fertilization as in cabbage. Subordinated to the breeding system are selection intensity, population size, and gene dispersal. Heritable variation would be at a minimum in a pure line; but varieties of self-fertilizing crops are rarely represented by pure lines. The different causes of variation within varieties which should be pure lines are: (*a*) residual hybridity of the original variety; (*b*) mutation and structural change; (*c*) seed admixture; (*d*) cross-pollination. Cultivated plants show a continuous range in breeding systems from self-incompatibility and diœcism giving full outbreeding, to regular self-pollination and vegetative reproduction, giving full inbreeding or its equivalent.

Experiments with rye indicate that thirty-six plants can maintain a variety in its original form; but six plants are too few to avoid inbreeding depression and undesirable loss of variability in cross-breeding crops. Cultivated plants are selected for a special environment. When human selection is relaxed the subsequent deterioration shows us how natural populations with similar breeding systems will respond to changes of environment. A study of the dispersal of pollen of cultivated plants shows that inter-crossing is mainly confined to immediate neighbours, though finite amounts of crossing occur up to large distances. The part which this dispersal plays in determining population structure again depends on the breeding system.

Dr. H. G. Baker gave an account of gene-flow between inter-fertile species. In 'pauciform' hybrids, the individuals are without fertility and cannot be back-crossed to their parents or form segregating swarms by selfing. Other hybrids, termed 'multiform', are sufficiently fertile to perform either of, or both, these acts. Yet in 'multiform' hybrids gene-flow is often restricted or even absent. In the sub-tribe Madiinæ of Compositæ, lack of internal harmony within the plant may lead to certain 'recombination types' failing to endure serious competition. Self-pollination reduces frequency of hybrids, as do also cleistogamy as in *Viola* and apomixis as in *Poa*. Certation effects favouring pollen-tubes of the same species as the styles also reduce interspecific hybrids as in *Melandrium*. Interspecific hybridization is more likely to occur where one or both species is under- rather than over-dispersed. Matrocliny may increase the possibility of gene-flow. Linkage hinders gene-recombination and may be of importance in preserving the parental types in natural populations. 'Variance of fertility' is sometimes seasonal. Internally determined restrictions on gene-flow are no less important than those imposed by the external environment. Some hybrid swarms develop under man's influence; others do not. When two kinds of plants come to occupy adjacent habitats, the exchange may occur of genes resulting in characters which are neutral so far as the ecological distinction between the kinds is concerned. With modification of the environment, characters excluded previously on ecological grounds may occur.

Dr. D. H. Valentine described interspecific hybridization between primrose (*Primula vulgaris*) and oxlip (*P. elatior*) in woods in certain regions of East Anglia. The populations of individual woods are isolated from one another. Some woods contain one or other of the pure species, others contain the two species and their hybrids. Where the species meet, they occupy distinct areas in the wood, probably because of their different ecological preferences. Hybrids are always frequent, but they do not outnumber the pure species. From reciprocal artificial crosses, a low yield of viable seeds is obtained, and the vigour of the F_1 hybrids is variable. A somewhat better yield of seed is obtained when the F_1 hybrid is selfed or backcrossed. There are thus both ecological and genetical barriers which tend to prevent fusion of the species. The condition appears to be one of equilibrium, which may shift in one direction or the other as variations of local climate and other environmental factors occur. Efficient barriers of more than one kind separate oxlip and cowslip (*P. veris*), and the hybrid between primrose and cowslip, which is partially fertile, is of widespread occurrence; but extensive hybrid populations are apparently rare, perhaps because of the marked ecological differences between the species.

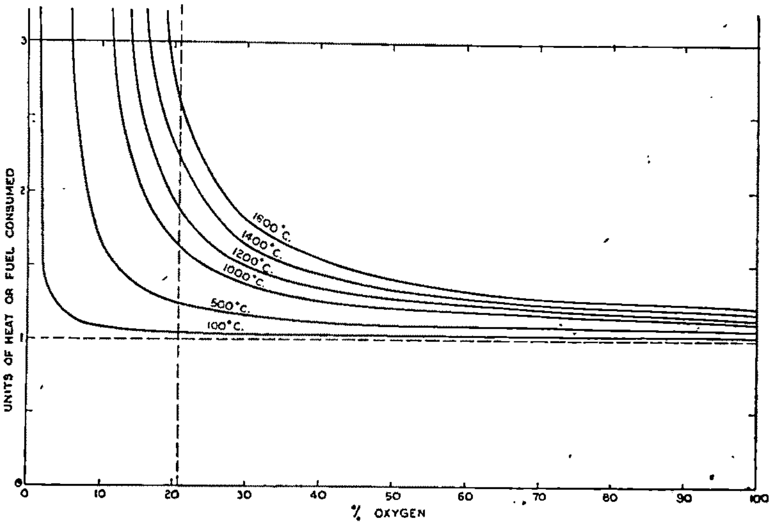
In the discussion following the five papers, Dr. J. M. Rasmusson commented upon the successful attempt to combine the points of view of wild and cultivated plants, of the botanist and the plant-breeder. In sugar-beet it had been found that from five to ten plants were too few and forty to sixty plants enough to prevent inbreeding depression. A distance of 200 yards prevents crossing in the open in sugar-beet. Dr. C. D. Darlington questioned Mr. Crosby's explanation of the spread of homostylous plants in his primrose populations. Prof. J. G. Nannfeldt urged that the experimental methods of genetics and ecology should be increasingly applied to the native flora. Captain C. D. Diver noted that while there were considerable differences in breeding mechanisms between animals and plants, results were often similar. Mr. A. J. Wilmott asked that more investigation should be undertaken on chances of cross-pollination by wind with increasing distance. Mr. O. H. Frankel maintained that seed merchants in Great Britain aimed for saleability (largely a matter of uniformity), not quality (productivity).

APPLICATION OF OXYGEN TO STEEL-MAKING

By Dr. W. C. NEWELL
British Iron and Steel Research Association

MANY modern technical developments have been made by preparing materials of greater suitability for specific purposes from the naturally occurring materials which were employed earlier. An obvious example of this is seen in the superior materials now used for building construction and a comparison with natural clay which is still used in some places. Though air has, wittingly or unwittingly, been used for combustion from very early times, the bulk manipulation of gases on a commercial scale is such a modern development that the commercial use of oxygen for combustion is only now just becoming possible. The use of an oxygen-enriched air blast does not appreciably increase the heat of combustion, but it does reduce the cooling effect of the nitrogen present in air which is normally passed through furnaces. The magnitude of this effect is appreciated when it is pointed out that during the combustion of carbon to the dioxide with ordinary air, the weight of nitrogen involved is nearly ten times the weight of the carbon. Under certain conditions thermal recuperation or regeneration of the heat from the gases leaving the furnace is possible, but at high temperatures this is inefficient and costly.

The magnitude of the loss of sensible heat with the nitrogen passing off from furnaces is greater the higher the temperature, and for steel-making temperatures, of say up to 1,700° C., it becomes of such major importance that many attempts have been made in various parts of the world to employ oxygen-enrichment to improve the thermal efficiency of steel-making processes. Recently[1] full technical details have been published of the way in which oxygen-enrichment is being successfully applied on a continuous production basis at Messrs. Cattons' steel foundry in Leeds. The accompanying chart shows for the combustion of carbon to dioxide the number of



Effect upon fuel consumption of emergent gas temperature for the reaction: $C + O_2 \rightarrow CO_2$

units of fuel consumed for varying percentages of oxygen used in the blast of the furnace, the heat units consumed above one unit being those wasted as sensible heat with the emergent nitrogen. From this chart it will be seen that, for emergent gas temperatures below 1,000° C., little thermal gain can be effected by the use of oxygen enrichment, but that the gain increases rapidly for higher temperatures. Further, it is seen that there is little thermal advantage to be gained by raising the oxygen content of the blast beyond about 40 per cent.

A steel foundry requires molten steel to be supplied intermittently and at a higher temperature than for the production of steel ingots, and at these trials at Leeds, by using 30 per cent oxygen in the blast (as compared with normal approximately 20 per cent in air), it has been found possible to obtain molten steel 50° C. hotter with a simultaneous economy in costly ferro-silicon, which is normally employed as a fuel of high calorific value. Alternatively, advantage has been taken of this gain in thermal efficiency by adding cold steel scrap or ferro-alloys to the steel after the blowing operation. Thus substantial economies have been shown to be practicable, and the way has been opened up for the use of the side-blown Bessemer converter for the production of more highly alloyed steel. Moreover, it has been shown that the use of molten steel of higher temperature does not necessarily mean that there will be any greater attack upon the refractory material of the converter lining or upon the sand of moulds into which the steel is cast; indeed, the penetration of liquid steel between the sand grains has been less than usual, and the surface finish of the castings has been better.

The most striking result of the use of oxygen enrichment is that the flame issuing from the converter is far brighter than usual and the steel is made in about half the usual time. This is a reminder of those early experiments of Priestly which are repeated to this day in school laboratories to demonstrate the enhanced rate of combustion of a wooden splint in oxygen. Normally, during the early stages of blowing a side-blown Bessemer converter, silicon is being oxidized and there is very little flame; and the flame later is associated with the combustion of carbon monoxide at the mouth of the vessel. Using oxygen enrichment and a very low silicon content in the molten metal, the flame is observed right from the commencement of the blowing operation; but it is interesting to note that in spite of the fact that under these conditions the flame is of far greater intensity the agitation of the metal within the vessel appears to be less, as judged by the lower loss of ejected metal. In fact, with higher oxygen contents in the blast there are distinct indications that the metal is not agitated enough to ensure uniform oxidation. These observations are leading to trials of modifications in the design of the vessel, and especially the tuyeres, which may lead to greater efficiency of operation and to the extension of this process of steel-making for bulk ingot steel production.

The industry concerned with the large-scale production of oxygen is making great efforts to keep pace with the rapidly increasing demand; but some idea of the magnitude of the problem is gained when it is pointed out that in the steel foundry referred to about 1,500 cubic feet of oxygen are consumed per ton of steel made, this volume of oxygen weighing about one hundredweight.

At the present time, large consumers of oxygen are supplied with liquid oxygen, which though costing more to produce than oxygen supplied in gaseous form, is much cheaper to transport. However, at the works referred to, about eight tons of oxygen are consumed per week, and this makes necessary a regular shuttle service of lorries carrying liquid oxygen. Thus it appears that the magnitude of the demand is going beyond the economic limit for the supply in liquid form, and extensive plans are being made for the supply of oxygen by some form of gas pipe line to those parts of Britain where the demand for oxygen for such purposes is likely to be great. At the present moment, the high cost of oxygen supplied in liquid form is likely to restrict extensive application of the process to steel foundries where greater advantage can be taken of the technical improvements brought about by oxygen enrichment.

OBITUARIES

Prof. S. W. J. Smith, F.R.S.

Samuel Walter Johnson Smith, formerly Poynting professor of physics in the University of Birmingham, died on August 20 in his seventy-eighth year. His death will be deeply regretted by many former students of the Royal College of Science, London, and of the University of Birmingham, who will remember him gratefully both as a teacher and as a friend.

The son of a well-known railway engineer, Smith was born in Scotland in 1871 and went first to school in Tayport and Dundee, completing his early education at Rutherford College, Newcastle-upon-Tyne. In 1887 he entered the Royal College of Science with a national scholarship, and after completing the course there went to Trinity College, Cambridge, in 1891 with a major scholarship. He obtained a first in Part 1 of the Natural Science Tripos in 1892 and in Part 2 he had the rare distinction for those days of obtaining a double first, in physics and chemistry. Afterwards he was appointed Coutts-Trotter Student and worked in the Cavendish Laboratory under Sir J. J. Thomson until 1896.

Upon leaving Cambridge, Smith returned to the Royal College of Science, London, as senior demonstrator in physics and became assistant professor in 1912. He obtained the D.Sc. degree of London in 1908 and was elected a fellow of the Royal Society in 1914. During this period at South Kensington, he took a prominent part in the work of the Physical Society of London, being honorary secretary from 1908 until 1916 and vice-president during 1916–19. In addition to his heavy secretarial and teaching work, he did a great deal of research in this phase of his career and it was probably his most fruitful period.

In 1919 he succeeded Poynting as professor of physics at Birmingham and undertook the difficult task of coping with the many problems arising from the First World War, particularly those resulting from a great increase in the number of students. Somewhat later, about 1924, he organised a new honours course in physics, as up to that time only a general degree had been awarded. He was dean of the Faculty of Science from 1929 until 1932. In 1936 he retired and was appointed emeritus professor, and from that time until his death he lived a quiet and somewhat secluded life.

In his researches, Smith devoted himself almost exclusively to two fields of work. His first investigation arose quite naturally from his training in both physics and chemistry; he selected it himself and worked at it in the Cavendish with very little guidance. It dealt with the contact difference of potential arising at a mercury – electrolyte interface, and necessitated a great deal of careful observation using various types of capillary electrometer; the conclusions were published in the *Phil. Trans. Roy. Soc.* of 1899. Later, at South Kensington, with the assistance of collaborators, he extended and amplified this work, turning to problems of electrolytic resistance and ionic migration. The results of these experiments were published in a series of papers in the *Phil. Mag.* and the *Proceedings of the Physical Society*.

The second and perhaps the more important field of Smith's work started from a problem in ferromagnetism suggested to him at South Kensington by Sir Arthur Rücker, who surmised that an examination of the magnetic properties of meteoric iron might throw some light upon the cause of terrestrial magnetism. It soon became clear, however, that this was no problem in terrestrial magnetism but rather a problem from the domain common to geology, metallurgy and physics. The meteoric irons are, in fact, examples of iron – nickel alloys which have cooled with extraordinary slowness and show structural characteristics not reproducible by artificial means. Smith worked alone on this question for a number of years, using a method of investigation simple in principle but requiring great skill and care in execution. He published the results of his observations in an important memoir appearing in the *Phil. Trans. Roy. Soc.* for 1908.

This work was continued at Birmingham where, in addition to extensions of the magnetic technique, metallographic and X-ray methods were called into service. During these years a great deal of assistance was given by the late James Young, who published a number of papers dealing with the results of the X-ray examination of some of these meteoric specimens. The magnetic and metallographic work was carried out under Smith's direction, and there exists a great deal of unpublished material. It is probable that towards the end of his life Smith was searching for some far-reaching synthesis of the observations which he failed to discover. In March 1939 he published in *Nature* a very brief summary of the work and of his tentative conclusions.

Smith was a man of great personal charm with a manner at once disarming and dignified. Over many younger men he exercised a special fascination, arising from a genuine gift of sympathy and also from the interest of his conversation. As a teacher he was held in the highest esteem throughout his life. In 1900 he married Dorothy Muriel Stamp who, together with an only daughter, survives him.

M. L. OLIPHANT
A. A. DEE

King Ferdinand of Bulgaria

EX-KING FERDINAND OF BULGARIA, who died recently at Coburg at the age of eighty-seven, was born a prince of Saxe-Coburg Gotha. From early youth he had a passion for natural history; but he was no mere amateur, and his studies of botany, entomology and ornithology were serious and scientific. Of the three, his chief interest lay in ornithology, and he first made his appearance among ornithologists at the age of thirteen, under the guidance of Crown Prince Rudolf of Austria, himself an ornithologist of repute. In 1887 Prince Ferdinand joined the Deutsche Ornithologische Gesellschaft, of which Society he remained patron until his death; in later years he was elected an honorary member of the Royal Hungarian Institute of Ornithology and also of the British Ornithologists' Union. In 1879 he made an official visit to Brazil the opportunity for studying the bird-life of South America, and on becoming Tsar of Bulgaria he gave every encouragement to the study of the ornithology of the Balkans and the collection of specimens. The museums and zoological gardens of Sofia are further and concrete evidence of his active interest.

After his abdication, he retired to Coburg, where he devoted most of his time to his private museum and large collection of living birds, though he frequently visited his castle in the Carpathians. The aviaries at Coburg contained more than eight hundred specimens, including many rare species, most of which had been collected by King Ferdinand himself, and he knew where each one had been obtained or purchased. He would spend hours in his aviaries studying the habits of the birds. A section of the gardens was set aside for wild-flowers which the King had either collected himself or had had given to him, from every part of the world; and, as with the birds, he knew the history of each plant.

In 1927–28 King Ferdinand made a collecting trip to South America and described his experiences in his book "Der König reisst". In 1929 he made an expedition, accompanied by his niece, Princess Victoria, Countess of Solms-Rödelheim, a keen botanist, and his museum curator, Dr. Hans von Boetticher, to Victoria Nyanza and the mountains of equatorial Africa. His account of the expedition, with a report on the ornithological observations, compiled by Dr. von Boetticher, was published as a special supplement of the *Journal für Ornithologie* in 1930. He was a regular attendant of the meetings of the Deutsche Ornithologische Gesellschaft which were held each year in various parts of Germany and took part in all the ornithological excursions, however arduous. In 1934 he attended the International Ornithological Congress at Oxford, including the visit to the bird islands off the Pembrokeshire coast. His enthusiasm and activity were such that even at the age of seventy-six, in 1937, he was considering the possibility of a trip by aeroplane and motor-car from Cairo to the Cape in order to study the bird-life throughout Africa.

He was a brilliant linguist, and in fact it was difficult to discover how many languages he did know, for he would turn with bewildering speed and facility from French, German, English, Bulgarian to Portuguese. His dominating personality, astuteness as a politician and the unpopular role he took in the destinies of Europe have always been emphasized; but his love of beautiful things, his great generosity to the cause of science and to his friends, his delightful sense of humour and a surprising simplicity are sides of his character which have generally been missed.

PHYLLIS BARCLAY-SMITH

WE regret to announce the following deaths:

Peter A. Bungart, for nearly twenty-five years associated with the Department of Geology and Palæontology of the Cleveland Museum of Natural History, who was a distinguished collector and preparator of fossil fish, on July 30, aged seventy-two.

Prof. Alexandr Orlov, professor of petrography and chemical mineralogy at the Charles University of Prague, known for work on the origin and occurrence of groups of ore-bearing rocks and soils, the metamorphosis of limestones and dolomites and especially for his petrographic studies of Czech garnet deposits, aged forty-nine.

Prof. D. A. Welsh, emeritus professor of pathology in the University of Sydney, where he held the chair from 1902 until 1936, on May 13, aged eighty-two.

NEWS and VIEWS

Botany at Cambridge:

Prof. F. T. Brooks, C.B.E., F.R.S.

ON September 30 Prof. F. T. Brooks retired from the professorship of botany in the University of Cambridge, which he has held since 1936. When he succeeded Sir Albert Seward he became head of a large and well-organised department, which continued to expand and prosper under his direction in spite of the difficulties and restrictions of the war years. At the present time, accommodation in the Botany School is strained to its utmost by ever-increasing numbers of research students, and investigations are being made in all the main fields of botanical science, while the number of undergraduate students is well maintained. During his tenure of the chair, Prof. Brooks has continued his researches in plant pathology, and during his career he has been responsible for the training of a large number of mycologists and plant pathologists who now hold important posts in many parts of the world. His wise guidance and administrative ability have been freely extended to the University Botanic Garden; he has acted as chairman of its executive committee and as secretary of the managers of the Cory Trust. His work has extended beyond the University; he was for five years an active member of the Agricultural Research Council and has been one of the general secretaries of the British Association for the Advancement of Science. He will continue to live in Cambridge and to carry on his researches in the Botany School.

Prof. G. E. Briggs, F.R.S.

PROF. G. E. BRIGGS will succeed Prof. Brooks as professor of botany. He will be the ninth holder of the chair, which was founded in 1724, and the first plant physiologist to be appointed to it. His researches on photosynthesis and growth have brought him a world-wide reputation as a clever experimenter and a critical and original thinker. A pupil of F. F. Blackman, he has been head of the Sub-department of Plant Physiology in the Botany School since 1937, and was raised to the rank of professor in 1946. He is a man of wide interests, distinguished as a teacher, and he has had considerable administrative experience in the University and as a fellow and officer of St. John's College.

Solar Eclipse of November 1: British Expedition to Mombasa

A SMALL expedition from the Royal Observatory, Greenwich, under Dr. R. d'E. Atkinson, is proceeding to Mombasa to observe the eclipse of the sun on November 1; the purpose is to try out a method of correcting the moon's place from observations on the thin crescent of the sun seen from a station where the eclipse just fails to be total. Measurements of the position-angle of the line of cusps, as a function of the time, can give corrections to the differential co-ordinates of sun and moon which are independent of any assumption about their apparent radii, and independent also of irradiation if the sky is uniform. If a large number of such measures is made, the effects of irregularities of the moon's limb also cancel out to a considerable extent. In the neighbourhood of Mombasa, where the eclipse is nearly 98 per cent total, the position-angle swings round through about 70° in $2\frac{1}{2}$ minutes; it is hoped to obtain 3,000 timed pictures on 35-mm. film in this interval. The camera will be stationary, and the trail of successive images produced by the sun's diurnal motion will give the zero of position-angles. An ordinary small visual telescope-lens, stopped down to about $f/40$, is being used, in conjunction with a green filter and exposure times of 1/1,000 sec. Special time-signals will be sent from Rugby, and these will be recorded, together with the instants of the shutter-openings, on tape-chronographs which have been made at Abinger. The accuracy of the results will be limited by uncertainties about the contour of the moon's limb;

it seems certain that if the limb were smooth the moon's place would be determined with considerably greater accuracy than that with which it is at present computed in the Nautical Almanac. Whatever the limb-effects may be, the accuracy should be higher than that which results from six thousand ordinary occultations, since the timing is considerably better than is possible with visual methods, while all effects due to personality, systematic time-differences between stations, and real changes of libration are eliminated. If the method works out as well as is hoped, it will probably be used for long-range geodetic purposes; the accuracy will then be more severely limited by our ignorance of the moon's limb, since considerable changes in the libration are inseparable from a long shadow-path. However, the accuracy should still be considerably greater than can be obtained, for the same purpose, by merely timing the instants of contact, since in that case all the emphasis is on some one point of the limb at each contact; a chance error at that point can cause a large error in the time.

Frozen Foods Consultative Group

To ensure the fullest co-operation and collaboration between the various research organisations engaged in the field of food, and also that inquirers will be directed to the best sources of information, the Frozen Foods Consultative Group was set up last year. It consists of representatives of research organisations, official and semi-official, under the chairmanship of the director of food investigation, Dr. Franklin Kidd. The objects of the Group are in the main the exchange of information on research investigations in progress on the preservation of food by quick-freezing processes so as to prevent overlapping and to discover gaps in research programmes. The terms of reference are: (*a*) to table and discuss the results of investigations into new developments in methods of preserving food by freezing; (*b*) to consider the planning of further investigations (each organisation to retain its own independence and the responsibility for its own programme); (*c*) to maintain contact between investigators in such fields as packaging and engineering which bear on preservation by freezing; (*d*) to direct inquirers in industry to the best sources of information. The following research organisations and stations are represented: Low Temperature Research Station, Torry Research Station and Ditton Laboratory (all of the Department of Scientific and Industrial Research); Scientific Adviser's Division, Ministry of Food; British Food Manufacturing Industries Research Association; Printing, Packaging and Allied Trades Research Association; British Baking Industries Research Association; Fruit and Vegetable Preservation Research Station, Chipping Campden. The Group has power to invite to its meetings representatives of other organisations such as the Refrigerated Cargo Research Council, the Institute of Refrigeration and the Food Manufacturers Federation. The secretary of the Group is Mr. P. R. P. Claridge, Food Investigation Organisation, Lloyds Bank Chambers, Hobson Street, Cambridge.

Petroleum Films Bureau

IT may not be generally known that there exists in London an organisation specializing in circulation (free of charge to responsible bodies such as educational and Service authorities) of 35 mm. and 16 mm. sound and silent documentary instructional films. The August catalogue has reached us from the Petroleum Films Bureau, 46 St. James' Place, London, S.W.1, sponsors of this scheme, from which it is clear that the range of subjects covered is not limited to varying aspects of the oil industry. Titles of general interest include the microscope, microscopy of opaque objects, hydraulics and hospital service. "How Oil is Produced and Refined" is covered by fifteen different reels giving a total of more than three hours showing. Other sections deal with automobile engineering and road safety for children. Short synopses of each film are available; also lantern slides, with appropriate lecture notes, on the subject "About Oil" can be borrowed to illustrate the early history of oil, its nature, origin, production, refining and transportation. This is a valuable scheme, capable of great expansion and certain of support in lecture theatre, classroom, drill hall and, presumably, the home.

Fertilizer Manufacture in East Africa

A SCIENTIFIC mission from East Africa is at present on a short visit to the United States to study the methods employed by the Tennessee Valley Authority in the manufacture of fertilizers. Large deposits of rock phosphates are known to exist in Uganda, and it is expected that the knowledge gained from this visit can be applied to the exploitation of these deposits when hydro-electric power becomes available from the Owen Falls scheme. The members of the mission are: Dr. A. J. V. Underwood, industrial consultant in London to the East Africa High Commission; Mr. H. B. Stent, acting chairman of the East African Industrial Research Board; Dr. K. A. Davies, director of the Geological Survey, Uganda; and Mr. C. R. Westlake, chairman of the Uganda Electricity Board.

Life-Histories of Birds

THE United States National Museum has issued a number of bulletins dealing with the life-histories of various North American birds. The latest addition to the series covers the nuthatches, wrens, thrashers and their allies, and is a painstaking work. Mr. Burt, the author, says that he has endeavoured to give as full a life-history as possible of the best-known sub-species of each species, and has written more briefly of the related sub-species, by this method avoiding repetition and duplication. He has amassed much information which is presented in a clear and readable manner, the volume being illustrated by a large number of photographs, mostly excellent ones, the last, of a sage thrasher, being a particularly successful picture.

Edward Livingston Trudeau (1848–1915)

WHEN he was a student at the New York College of Physicians and Surgeons, Edward Livingston Trudeau, who was born on October 5, 1848, was taught to regard tuberculosis as an incurable disease. When, therefore, the celebrated physician Edward G. Janeway in 1873 diagnosed extensive tuberculosis in his left lung, his patient, who had recently graduated and married and whose brother had died of the same disease, felt he was under sentence of death and gave up his practice to spend his last days in the Adirondack Mountains. To his and everyone else's surprise he recovered, and in 1884 established the open-air Adirondack Cottage Sanitarium—the first in the United States. In the isolation of a primitive forest, badly crippled and single-handed, Trudeau preached and practised the gospel of fresh air and extolled the virtues of rest. Having read a translation of Koch's classic paper on the etiology of tuberculosis, he built himself a modest laboratory in his own home. Out of its ashes sprung the present Saranac Laboratory—the first of its kind in the United States. Trudeau wrote little on clinical subjects; but his laboratory studies are contained in a large number of valuable papers, including experiments on immunity and on the effect of fresh air on tuberculous rabbits. He was the first president of the National Association for the Study and Prevention of Tuberculosis. His optimism and charm endeared him to all his patients, perhaps the most famous of whom was Robert Louis Stevenson.

Convention on High Vacua

THE Society of Chemical Industry is sponsoring a convention on high vacua under the presidency of Sir Charles Darwin, director of the National Physical Laboratory, which is being organised by Mr. L. L. Maitland, director of British-American Research, Ltd., to be held at Gleneagles during October 12–13. Among the topics to be discussed are the applications of high vacua to plastics, dehydration, distillation generally and the distillation of fatty oils, the metallurgical industry and nuclear physics and atomic energy. Full opportunity will be provided for discussion. Information on accommodation and travel arrangements can be obtained from Mr. L. L. Maitland, British-American Research, Ltd., Block E.2, Hillington North, Glasgow, S.W.

Photo-electric Spectrometry Group

AN association has been formed of those interested in instruments for photo-electric spectrometry and their applications. It has been named the Photo-electric Spectrometry Group, without prejudice to its possible future affiliation to an existing scientific body. The inaugural meeting of the Group was held in Cambridge on July 16. Out of about a hundred and twenty who were invited, sixty-four attended. New instruments were on view and papers were read by Dr. E. R. Holiday (London Hospital) on "Adaptation of the Hilger Spekker and Medium Spectrograph for Photoelectric Work", and by Mr. G. H. Beaven (Thornton Research Centre, "Shell" Refining and Marketing Co., Ltd.) entitled "Notes on the Operation, Maintenance and Servicing of the Beckman Model D.U. Spectrophotometer".

The following were appointed officers of the Group: *Chairman:* Dr. J. R. Edisbury, Research Department, Lever Bros. and Unilever, Ltd., Port Sunlight; *Vice-Chairman:* Mr. G. H. Beaven, Thornton Research Centre, "Shell" Refining and Marketing Co., Ltd., P.O.B. No. 1, Chester; *Hon. Secretary:* Mr. W. H. Storey, Unicam Instruments (Cambridge), Ltd., Arbury Works, Cambridge; *Hon. Treasurer:* Mr. J. R. Stansfield, Hilger and Watts, Ltd., 98 St. Pancras Way, London, N.W.1; *Committee:* Mr. C. G. Cannon, Physics Department, University of Reading; Mr. B. S. Cooper, Research Department, General Electric Co., Ltd., Wembley; Dr. J. G. A. Griffiths, A.D.I. (Sc.), Air Ministry, Whitehall, S.W.1; Dr. E. R. Holiday, Research Department, London Hospital, E.1; and Dr. F. Wokes, Ovaltine Research Laboratories, King's Langley, Herts. Subjects on which it is proposed to hold further meetings or whole-day conferences are flame photometry (jointly with the Institute of Physics Industrial Spectroscopic Group), fluorescence, photo-electric recording of spectra, stray light, and reflexion spectra. A bulletin will be issued periodically for private distribution to members and will contain reports of meetings with details of papers and discussions. It will also include abstracts, a question and answer section, and give information about new designs and the location of spares for existing instruments. The subscription is 10*s.* per annum, commencing October 1, and includes the cost of the bulletin. Membership forms can be obtained on application to the honorary secretary.

National Research Council of Canada: Medical Fellowships

MEDICAL fellowships have been awarded by the National Research Council of Canada to thirty-one graduates in medicine to enable them to pursue post-graduate research during 1948–49. Distribution of the awards by the universities at which they will be held is as follows: McGill, 8; Montreal, 1; Queen's, 4; Toronto, 7; Western Ontario, 8; Manitoba, 1; Oxford, 1; Zurich, 1. These fellowships vary in amount from 1,500 to 2,500 dollars, depending on the previous training and experience of the candidates. The Division of Medical Research of the National Research Council also makes grants-in-aid to Canadian universities for medical research studies on approved subjects. During the present year, 118 such grants, valued at 264,173 dollars, are being held. The nominal value of the thirty-one medical fellowships awarded this year is 64,600 dollars.

Physical Society of London: Award of Charles Vernon Boys Prize

THE Charles Vernon Boys Prize of the Physical Society, given annually for distinguished research in experimental physics, is being awarded this year to Prof. S. Tolansky in recognition of his work in interferometry. The Prize will be presented at a meeting of the Society on October 8, when Prof. Tolansky will give an address on "Current Investigations with Multiple-Beam Interferometry". Prof. S. Tolansky has held the chair of physics at the Royal Holloway College, University of London, since 1947, and has done extensive research work in optics and spectroscopy; during the war years he was engaged on research in connexion with atomic energy.

Prof. R. W. Wood, professor of experimental physics at the Johns Hopkins University since 1901 and research professor since 1937, will give an address to the Society before the award of the Charles Vernon Boys Prize, his subject being "Spontaneous Deformation of Crystals". Prof. Wood is receiving an honorary degree of D.Sc. from the University of Oxford.

Lectures on the Atomic Age

THE Sir Halley Stewart Trust has arranged a course of six free lectures on "The Atomic Age", to be given at the Memorial Hall, Farringdon Street, London, on Tuesdays, beginning October 26, at 6 p.m. The speakers will be Prof. M. L. Oliphant, on "The Scientific Achievement"; Prof. P. M. S. Blackett, on "The Military Consequences of Atomic Energy"; Mr. R. F. Harrod, on "The Economic Repercussions of Atomic Power"; Lord Russell, on "Our Scale of Values in the Atomic Age"; Mr. Lionel Curtis, on "The Political Repercussions"; and Prof. D. W. Brogan, on "America as Atlas". For free reserved seats application should be made to the Secretary, Sir Halley Stewart Trust, 167 Strand, London, W.C.1.

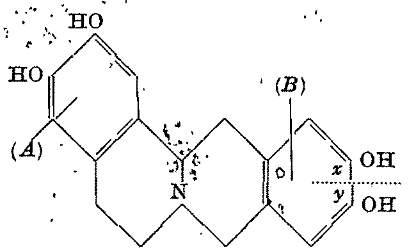
LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications

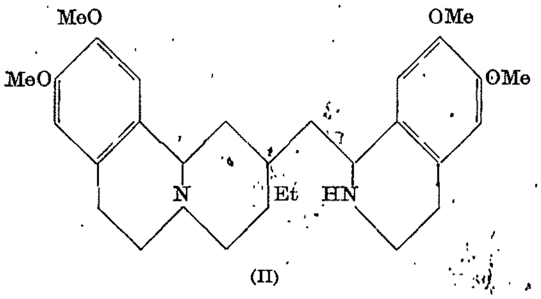
Structure and Biogenesis of Emetine

In making favourable comment on Woodward's ingenious suggestion respecting the biogenesis of strychnine[1], the hope was expressed that further speculation of a similar kind would be based on a comparable "degree of coincidence". The remarkable development mentioned below certainly meets this requirement. It provides an outstanding example of interaction of results in two fields, strengthening theoretical conclusions in both of them.

I noticed that (excluding consideration of the methylation of phenolic hydroxyls) emetine could be constructed from three molecules of dihydroxyphenylalanine and one of the formaldehyde equivalent, assuming a fission of one aromatic nucleus on Woodward's lines. Following these quite closely, it will be noted that the hydroxyl in the meta position to the side-chain of the amino-acid becomes an aldehyde group; that in the para position is found in the alkaloid in a state of oxidation equivalent to that of an alcohol. Postulating exactly the same circumstances in the case of the stages leading, on this hypothesis, to emetine, we arrive without ambiguity at a single formula (II). Thus the *nor*-pseudotetrahydroberberine (I) represents the familiar *nor*-laudanosine of the Winterstein – Trier hypothesis condensed with formaldehyde or its equivalent. What has long been known[2] about emetine proves that our next stage cannot be the degradation of the *A*-nucleus. If we assume the oxidative degradation of the *B*-nucleus, as indicated by the dotted line, and so that *x* becomes a formyl group, and the chain beginning with *y* is fully reduced, and later that the new aldehyde condenses in the usual manner with dihydroxyphenylalanine (decarboxylated at some stage) to an *iso*quinoline derivative, then, after O-methylation, emetine would be (II).



(I)



(II)

No special importance was attached to this speculation until, in the course of a discussion with Dr. M. J. S. Dewar, he wrote down formula (II) as the most likely interpretation of results described in three recent communications[3] on the subject of the chemistry of emetine. Of these, the work of Späth, and of Pailer, solves the problem of the arrangement of carbon atoms in the chain connecting the *iso*quinoline nuclei; that of Karrer and his co-workers supplies a detail which indicates the relation of this carbon skeleton to the tertiary nitrogen.

Thus the constitution (II) appears to be firmly established by these recently disclosed experiments, and by the earlier investigations. It is surely significant that, without knowledge of the recent publications, the same constitution was deduced by applying Woodward's theory of biogenesis of strychnine to a complex member of the *iso*quinoline group.

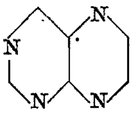
A Synthesis of Pteridine

Although many derivatives of pteridine, both natural and synthetic, are known, the parent substance pteridine (I) does not appear to have been described. This substance has now been prepared by the condensation of 4 : 5-diaminopyrimidine with glyoxal bisulphite.



I

4 : 5-Diaminopyrimidine has been described by Isay[1], but it is more readily available by a slightly modified procedure. 2-Chloro-4-amino-5-nitropyrimidine, m.p. 232° (Isay, *loc. cit.*, gives m.p. 217°), is hydrogenated in methanol over a nickel catalyst to give 2-chloro-4 : 5-diaminopyrimidine, m.p. 232° (found: C, 33·3; H, 3·7; N, 38·7; Cl, 24·6. $C_4H_5N_4Cl$ requires C, 33·2; H, 3·5; N, 38·8; Cl, 24·5 per cent). Catalytic dehalogenation over palladium on charcoal in the presence of barium oxide gives 4 : 5-diaminopyrimidine, m.p. 204°, which forms a crystalline nitrate decomposing without melting above 260° (found: C, 27·8; H, 4·0; N, 40·0. $C_4H_7O_3N_5$ requires C, 27·7; H, 4·1; N, 40·5 per cent). Reaction of the diaminopyrimidine in aqueous solution with glyoxal bisulphite gives pteridine which crystallizes from alcohol in pale yellow plates, m.p. 140° (found: C, 54·3; H, 2·9; N, 42·9. $C_6H_4N_4$ requires C, 54·5; H, 3·05; N, 42·4 per cent).

Pteridine is soluble in water and alcohol and readily sublimes *in vacuo*. Its ultra-violet absorption spectrum in aqueous solution at *p*H 5·8 shows a sharp maximum at 299 mμ with $\varepsilon = 7,890$ (Beckmann spectrophotometer), and in neutral or alkaline solution it shows a violet-blue fluorescence in the ultra-violet. It forms a picrate m.p. 117·5° (found: C, 35·9; H, 2·8; N, 24·6. $C_{12}H_7O_7N_7.2H_2O$ requires C, 36·2; H, 2·8; N, 24·7 per cent), and an oxalate which decomposes without melting above 128° (found: C, 37·5; H, 3·5. $C_8H_6O_4N_4.2H_2O$ requires C, 37·2; H, 3·9 per cent).

Chemical Assay of Streptomycin *B* (Mannosido – Streptomycin)

MORRIS[1] has recently described the use of a new reagent (0·2 per cent anthrone, a reduction product of anthroquinone, in 95 per cent sulphuric acid), for quantitative determination of carbohydrates. We have found that it can be used not only for distinguishing streptomycin *B* (a mannoside) from streptomycin *A*, but also for estimating the amount of the former present in a mixture. The glucosamine moiety, present in both molecules, apparently does not react with the reagent. Results obtained are in accord with those calculated from biological and chemical assays, making the accepted assumption about the relative biological activities of the two streptomycins.

It is hoped to publish elsewhere details of the analytical procedure, with some typical results.

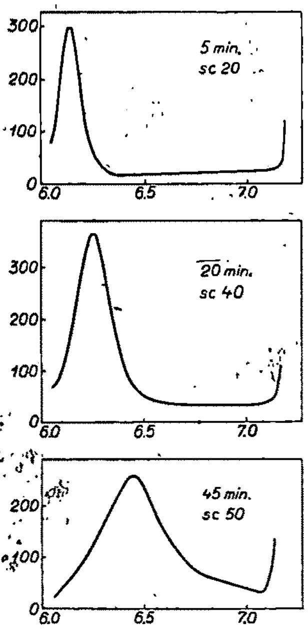
Molecular Weight of Malt-Amylase

IN an earlier investigation[1], the molecular weight of α-amylase from pig's pancreas[2,3] was found to be 45,000, as calculated from the values[4] $s_{20} = 4·50\,S$, $D = 8·05 \times 10^{-7}$ c.g.s. and $V_{20} = 0·70$. At this Institute a new method for the isolation of amylase from malt has been developed[5]. It was shown that by repeated purification of the albumin fraction from malt a preparation was obtained with high α-amylase and β-amylase activity. Therefore it was assumed that the amylase activity of malt is localized in the albumin fraction. By ultracentrifugation of the albumin fraction, only one peak was obtained. It must be stated here that malt-amylase is more polydisperse than α-amylase from pancreas.

A determination of the molecular weight was carried out on an amylase preparation with a saccharification activity[6] of 45,000 and a dextrinizing activity[7] of 57,400, calculated for the dry substance. The determination was carried out in a buffer solution with a concentration of 0·2 *M* sodium chloride, 0·03 *M* primary sodium phosphate and 0·02 *M* secondary sodium phosphate, *p*H 7.

Ultracentrifuge measurement. The accompanying sedimentation diagrams were obtained by centrifuging at 65,000 r.p.m.



Sedimentation curves for malt-amylase. In Table 1 the sedimentation constants for different concentrations are shown

Table 1

Conc. of amylase (per cent)	$s_{20}S$
0·19	4·62
0·28	4·44
0·31	4·96
0·32	4·22
0·41	4·76
0·45	4·12
0·75	4·69
1·00	4·44
1·05	4·39

The sedimentation constant is evidently independent of the concentration. An average value of the sedimentation constant is $s_{20} = 4·52\,S$.

Diffusion measurement. The determination of the diffusion constant was carried out in exactly the same way as for α-amylase from pancreas[1]. The resulting values of the diffusion constant are shown in Table 2.

Table 2

Diffusion time (sec.)	34,440	79,020	99,960	129,420	Average value
D_m	6·96	6·70	6·70	6·59	6·74
D_A	6·42	6·20	6·29	6·36	6·32

The agreement between D_m and D_A is good. The average value of $D = 6·53 \times 10^{-7}$ c.g.s. is used in the following. The value $V_{20} = 0·69$ was kindly determined by Prof. C. Drucker. Using these values, the molecular weight of malt-amylase is 54,000. Evidently this value is of the same order of magnitude as that for α-amylase from pancreas. It is an interesting fact that the amylase activity is associated with molecules with about the same molecular weight in both the plant and animal kingdom.

Action of Oxalyl Chloride on the Aromatic Hydrocarbons

THE action of oxalyl chloride on an aromatic hydrocarbon in the presence of anhydrous aluminium chloride and in a solvent (for example, carbon disulphide) can lead to the production of the aromatic acid as the chief reaction product. This may provide, too, a general method for the synthesis of *p*-alkylbenzoic acids[1].

Schönberg and Kraemer[2] isolated *p*-ethylbenzoic acid only by the interaction of oxalyl chloride, ethylbenzene, and aluminium chloride in carbon disulphide solution at a low temperature. No mention was made of the yield of the acid. On repeating their experiment and modifying the procedure so as to extract the acid directly from the reacting mixture with a dilute alkali solution, *p*-ethylbenzoic acid (m.p. 112–113°) was obtained in 43 per cent yield, rising to 66 per cent if equimolecular amounts of the substances interacted at room temperature. *p,p'*-Diethyldiphenyl ketone was also isolated.

The action of oxalyl chloride on the higher *n*-alkylbenzenes, under similar conditions, led to the formation of the corresponding *p*-*n*-alkylbenzoic acids in satisfactory yield. Results are shown in the accompanying table.

Action of oxalyl chloride on alkylbenzenes in carbon disulphide in presence of aluminium chloride at room temperature

Alkylbenzene	Acid formed	Yield of acid (%)
Toluene	*p*-toluic	60
Ethylbenzene	*p*-ethylbenzoic	66
n-propylbenzene	*p*-*n*-propylbenzoic	70
n-butylbenzene	*p*-*n*-butylbenzoic	50
n-amylbenzene	*p*-*n*-amylbenzoic	50
n-hexylbenzene	*p*-*n*-hexylbenzoic	40
n-heptylbenzene	*p*-*n*-heptylbenzoic	40
n-octylbenzene	*p*-*n*-octylbenzoic	3

The yield of the *n*-octylbenzoic acid was exceptionally low. This might be due to the fact that the reaction was not complete at room temperature.

Selective Development of Fission Tracks in an Electron-sensitive Emulsion

THE interpretation of records of nuclear reactions occurring in photographic emulsions is materially assisted by differences in the solidity and grain-frequency of tracks produced by particles of different ionizing power[1]. Discrimination between tracks of various particles can be enhanced by using emulsions with a range of intrinsic sensitivities[2]; to a lesser extent by varying development time and composition of developer[2,3]; or by applying oxidizing solutions between exposure and development[4].

Special emulsions have been produced which are sufficiently sensitive to record tracks of electrons[5,6], whereas at the other end of the range there are emulsions sensitive only to tracks of fission fragments[7,8]. The advantage of the latter is, of course, that fission fragments alone can be recorded in spite of a heavy background of radiation from other less strongly ionizing particles.

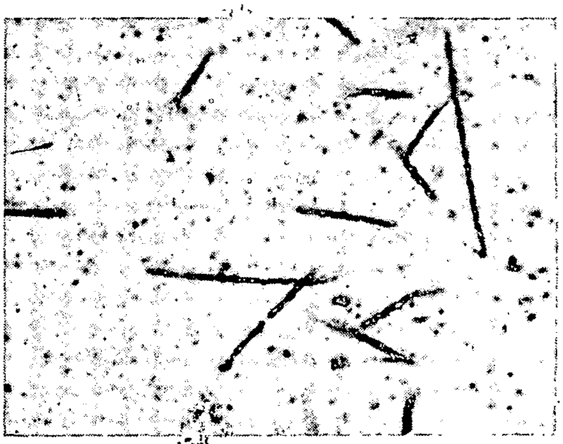

Fig. 1. Photomicrograph of tracks from uranium layer, dipping into NT.2*a* emulsion. Development 10 min. D.19*b*

It would be very convenient to be able to utilize an electron-sensitive emulsion for the selective recording of fission tracks, so that this whole range of results could be spanned with a single emulsion. A means of achieving this result by controlled under-development is the subject of the present communication.

Deliberate under-development implies that the development process will be stopped before all the exposed emulsion grains have been developed. Control of the results (particularly with thickly coated emulsions) is therefore facilitated by the use of long development times with severely restrained and slow-working developers. In preliminary tests it was noticed that a para-aminophenol solution, used at such a low *p*H that it would not even develop alpha-particle tracks, still gave strong development of abrasion marks in the emulsion surface. It seemed possible that such a solution would also develop fission tracks.

Glass plates were coated with a suspension of ammonium diuranate in gelatin (equivalent to 0·01 gm. uranium/cm.^{2}). These were packed in contact with 'Kodak' NT.2*a* plates, which have previously been shown to be capable of recording electron tracks[5,6]. Some of these were shielded with $\frac{3}{8}$ in. of lead and exposed to a flux of 5×10^{11} neutrons per cm.^{2} of plate in the nuclear pile at Harwell.

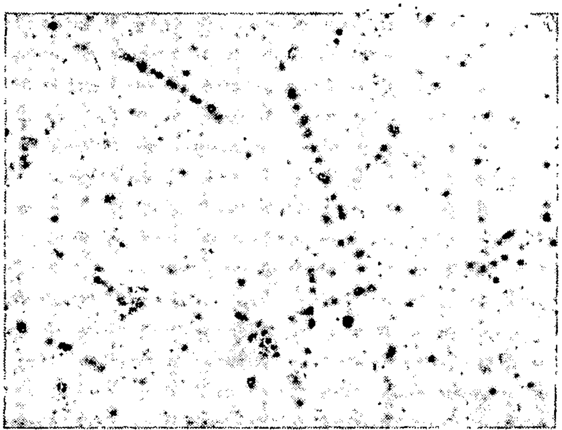

Fig. 2. Tracks given by 40-min. development in a low-energy para-aminophenol developer (solution I)

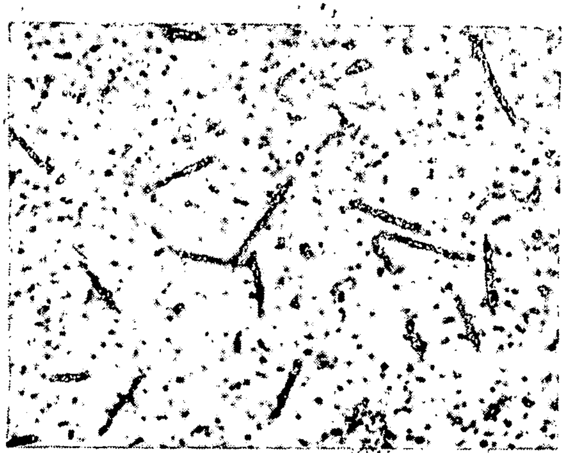

Fig. 3. Fission tracks dipping into emulsion on plate developed in solution I after exposure in the pile in contact with uranium

Strips exposed in the pile ('pile-plates') and controls left in contact with uranium only were developed for ten minutes at 70° F. in D.19*b* and for forty minutes in special low-energy para-aminophenol developers. These were prepared from three stock solutions: (*A*) contained 15 per cent para-aminophenol hydrochloride and 2½ per cent $NaH.SO_3$; (*B*) 5 per cent $Na_3PO_4.12H_2O$, 4 per cent Na_2SO_3 and 0·4 per cent KBr; and (*C*) 5 per cent $Na_2HPO_4.12H_2O$, 4 per cent Na_2SO_3 and 0·4 per cent KBr. Solution I contained 2 c.c. *A*, 20 c.c. *B* and 80 c.c. *C*. Solution II contained 2 c.c. *A* and 100 c.c. *C*.

The pile-plates developed a density of 4 in an 'Elonhydroquinone' developer (Kodak formula D.19*b*), and no tracks could be seen because of the high opacity, while the control showed solid alpha tracks (Fig. 1). In contrast to this, solution I produced on the control plates alpha tracks showing as tenuous chains of grains (Fig. 2), and the pile plate developed a density of only 0·5. Under the microscope, the latter showed solid fission tracks readily distinguished from the residual background (Fig. 3). Solution II, an even weaker developer, showed no alpha tracks at all, but still gave recognizable fission tracks on the pile plate (Fig. 4). Perfilov[4] obtained similar discrimination between alpha and fission tracks by treating the exposed plates in a dilute chromic acid bleach before development. We have been able to confirm the general nature of this result, and preliminary comparisons indicated that the discrimination is surprisingly similar to that given by these special para-aminophenol developers.

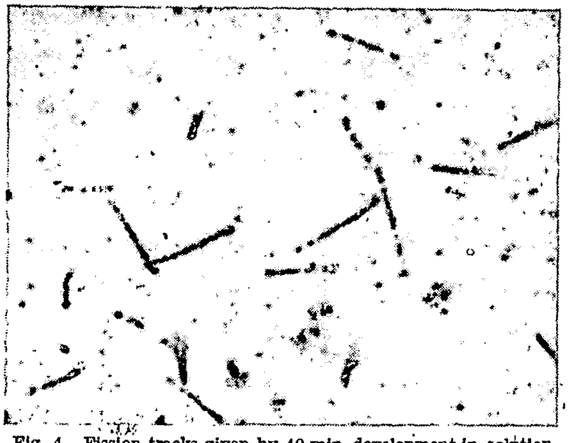

Fig. 4. Fission tracks given by 40-min. development in solution II, which cannot develop alpha tracks at all

Similar discrimination has also been obtained by using 'Elon' (methyl *p*-aminophenol sulphate), glycin and hydroquinone in solutions adjusted to give about the same development activity. The effect is thus not exclusive to one developing agent, but para-aminophenol and 'Elon' gave the more attractive results. Discrimination has also been obtained by adding progressive concentrations of potassium bromide to these solutions at higher *p*H values. On the other hand, substantially no discrimination between alpha and fission tracks was obtained by developing for only one minute in D.19*b*. A continuously graded series of developers can also be conveniently prepared by raising the proportion of stock solution *B* to increase the *p*H and developer activity, and some of these more active developers give considerable discrimination between alpha particle and proton tracks.

Considerable advantage may accrue if procedures of this type can be standardized without excessive trouble. The results given by such gross under-development are, however, likely to be particularly sensitive to small variations of temperature or composition. Reproducible results may, therefore, only be obtained by performing the development operation with the care used in other physico-chemical experiments.

I wish gratefully to acknowledge the help of the Director, Atomic Energy Research Establishment, Harwell, in obtaining neutron exposures, and to thank him for permission to publish these results which were obtained while working under contract to the Establishment.

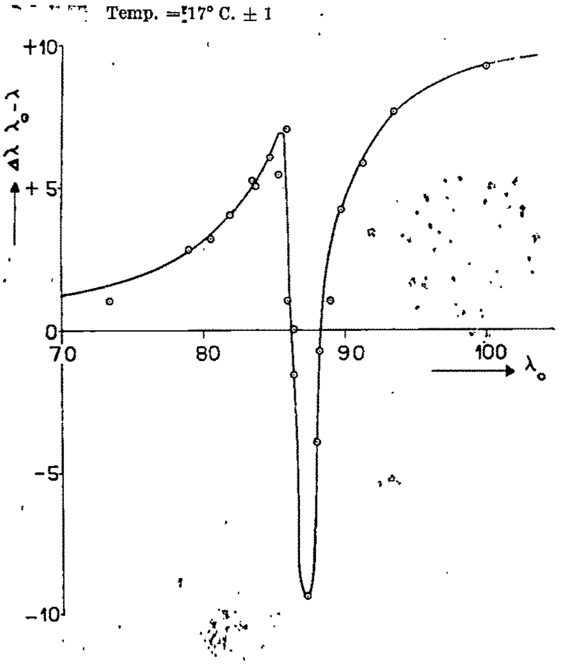
Anomalous Magnetic Behaviour of Nickel–Iron at High Frequencies

In the course of a series of experiments that is being carried out under the direction of Miss H. J. van Leeuwen in this Laboratory in order to determine the high-frequency magnetic permeability of ferromagnetic materials, a peculiar property of a nickel–iron alloy has been found.

Two concentric Lecher systems are used in the experiments, the outer conductor of both being made of copper, while the inner conductor of one is a copper wire, that of the other a nickel–iron wire (35 per cent nickel, 65 per cent iron). Both systems are coupled to an oscillator and the wave-lengths of standing waves are measured.

It can be shown mathematically that for a magnetic permeability μ greater than 1 of the ferromagnetic material, the wave-length λ for the ferromagnetic wire is smaller than the wave-length λ_0 for the copper wire. The results of the measurements in the interesting range are shown in the accompanying graph, the abscissa representing λ_0, which is practically equal to the wave-length *in vacuo*, while the ordinate signifies the difference $\Delta\lambda = \lambda_0 - \lambda$.



The graph resembles strikingly an anomalous dispersion curve. In a narrow interval, between $\lambda_0 = 86$ and 88 cm., the wave-lengths on the nickel–iron wire become considerably larger than those on the copper wire, which means that μ there is smaller than unity or even negative.

Similar experiments have been carried out previously in this Laboratory by J. Smidt[1] with a pure iron wire. This showed no anomalous behaviour except that the descent of the curve to zero near $\lambda_0 = 60$ cm. was much steeper than could be expected from theory[2]. A possible explanation would be that the wave-length for the anomalous behaviour of iron falls just in this region, the minimum of the curve being obliterated because the magnetic susceptibility of iron disappears below 60 cm.

It is expected that these and further experiments will reveal new information on the internal conditions of ferromagnetic materials.

A. Wiebberdink

The experiments just described can be interpreted in their essence by assuming that the magnetization induced in the material of the wire by a harmonically varying magnetic field is represented by a function of the frequency of the same type as that met with in the case of the electric polarization for a system subject to a harmonically varying electric field and possessing a resonance frequency.

As is well known[3], the magnetization in ferromagnetic substances in general is built up from three contributions: the irreversible displacements of the boundaries of the Weiss domains, the reversible displacements of these boundaries and the change in direction of the magnetic moments of such domains by the external field. At the frequencies and field-strengths here considered, the first cause is no longer operative[3]. The reversible motion of a boundary will, it is true, have a certain characteristic frequency of oscillation about its equilibrium position; but this will depend on local conditions such as stress, impurities, etc., and hence will vary from one boundary to another, thus not giving rise to a well-defined resonance frequency for macroscopic pieces of material. In its orientation, however, the resultant magnetic moment of a Weiss domain is bound to the crystal field, tending to give it preferential directions with respect to the crystal axes (while strong stress or the influence of a constant external magnetic field may supersede the crystal field). In consequence, the magnetic moment will precess about the preferential direction, and it is this precession frequency which acts as resonance frequency for the magnetization. In nickel the crystal field is equivalent to a magnetic field of about 100 oersted, whereas for iron the value is several times as large[3]. The double Larmor frequency in a field of that strength is about 3×10^8 Hz. In other words, it is located just in the proper frequency-range. As in the theory of electric polarization, an absorption will be associated with the anomalous dispersion, which can be described by a line-breadth. This is determined by the natural transition probability of the magnetic moment between its different stationary states in the crystal field, the transitions being brought about by the coupling of the magnetic moment with the conduction electrons and the lattice waves.

An investigation of the influence of stress and of a constant external magnetic field on the value of the resonance frequency will be very instructive and is being planned.

A more detailed discussion of the experiments as well as of the theory will be given in *Applied Scientific Research*.

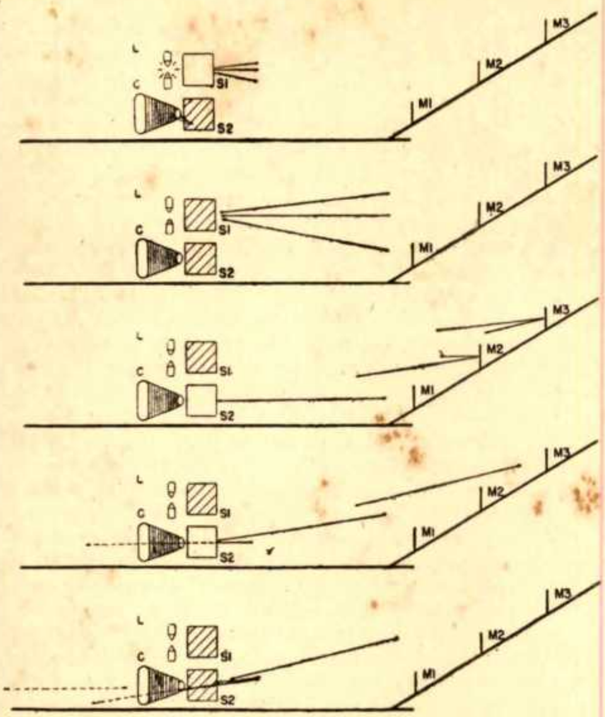
Brief Light Pulses using Kerr Cells

In connexion with certain studies of electrical discharges, we have found it necessary to develop an extremely fast shutter for photography. The electro-optic Kerr effect is used. Mounted 5·1 mm. apart in nitrobenzene in a glass Kerr cell, the electrodes are 12·7 mm. wide and 20·3 mm. long. Selected pieces of 'Polaroid *J*' film are placed outside the fused-on windows. The cells are subjected to single pulses of about 12,500 volts from a hydrogen thyratron and *RLC* pulse-forming network, thus admitting light to the lens of an ordinary camera. We have been photographing such intensely self-luminous objects as sparks and electrically exploded wires with exposures of a microsecond or less.

We report here a side-experiment designed to show directly the length of the segment of a light beam that we have been able to chop off with a Kerr cell.



L, light source ; *C*, camera ; *S* 1, 2, Kerr cell shutters ; *M* 1, 2, 3, mirrors

In this experiment, two shutters, separated by an optical path of a few metres, were arranged to be pulsed in sequence. If the second shutter were thus opened at a suitable moment following the opening of the first, to allow for the transit time of the light between them, a source of light in front of the first shutter could be photographed by a camera behind the second. If the time delay of the second shutter were appreciably different from the transit time, no light reached the camera. The light source was a wire electrically exploded just previous to the opening of the first shutter.

For convenience, the optical path was folded by using a plane mirror, so that the camera was just below the source. In our experiment, not one but several mirrors were used. These were all so placed as to be illuminated by the source, and all were in the field of view of the camera. Thus several optical paths were set up, each with its own mirror (see accompanying diagram). Since successive mirrors were separated by 30 cm., the optical path differences were 60 cm. By virtue of the finite speed of light, a brief sequential pulsing of the two shutters should, in any given exposure, show not all the mirrors to be effective in reflecting the light pulse. The accompanying photographs show the mirrors, located 30 cm. apart. Certain of them are seen to reflect the light ; from a count of these, the length of the light segment may be estimated. By altering the relative timing of the shutters, the reflexions can be made to appear in the near mirrors or the far mirrors.

For a semi-quantitative estimate of the length of the beam segment, the method was to compare visually the density of the photographed reflexions in two negatives, one of which had been exposed to two flashes and the other to a single flash. It was noted that seven of the images on the double exposure are more intense than the brightest image on the single exposure. From this it is deduced that the measured length of the beam, between half-intensity points, is about 4·2 m. Neglect of the inverse square law is approximately justified. This measured length depends upon the speed of the second shutter as well as that of the first. If we make the plausible assumption that the voltage applied to each shutter is a similar Gaussian function of time and calculate therefrom the variation of the transmittance of either shutter during the pulse, the distribution of the exposure among the several photographic images is predicted to be approximately Gaussian with a width at half-maximum which is about 23 per cent greater than that of either shutter. The actual length of the beam is thus $4{\cdot}2/1{\cdot}23 = 3{\cdot}4$ m. between half-intensity points. Furthermore, since 70·7 per cent of the area of the shutter transmittance function lies between abscissæ only 78 per cent as far apart as its half-value points, we may say that the effective length of the beam is only 2·7 m. Its duration is therefore 270 jiffies, or about 9×10^{-9} second. This last figure is in good agreement with the value calculated from the oscillogram of the pulses applied to the Kerr cells.

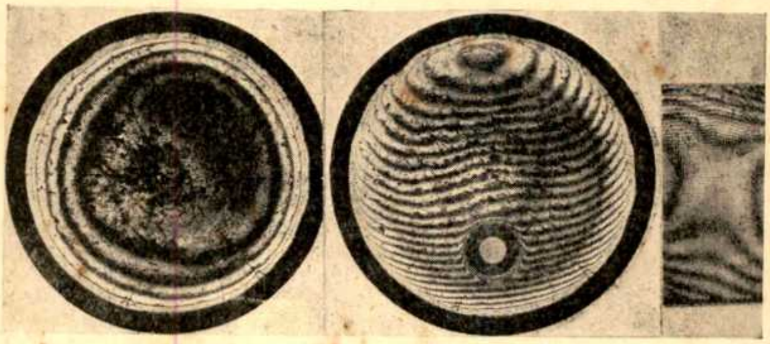
Liquid Surface Interferometry

THE property that liquid surfaces have of indicating level is frequently employed in physical and engineering metrology. Surprisingly little use is made of the property of flatness which, with certain reservations, is possessed by a reasonably extensive liquid surface, which provides a naturally reproducible reference basis. The earth's radius of curvature causes the centre of a liquid surface of 25 cm. diameter to project by only 12 A. above the true plane intersecting its



1 and 2 show two depositions of fringes in a liquid paraffin layer floated on a lapped cast-iron surface, and indicate that, apart from slight concavity at the centre, the metal surface is generally convex in shape. 3 shows two fringe systems obtained when a wedge plate of glass (20 cm. × 10 cm.) is supported over the liquid surface. *N.B.*—1 fringe in liquid paraffin and glass is equivalent to 0·18 μ ; in air the equivalent is 0·27 μ

perimeter, if the effect of capillary curvature at the boundary region is omitted from consideration.

Preliminary experiments at the National Physical Laboratory, with a liquid surface serving as the reference plane in one of the usual arrangements of a Fizeau interferometer[1], have yielded very promising results over a field of 25 cm. diameter. We find, however, that Rayleigh described long ago the use of a water surface for similar purposes during a Royal Institution lecture[2]. Our experiences are much the same as those described by Rayleigh, except that we find it important to use liquids of higher viscosity than water to avoid the vibrational troubles which he reported. Among the liquids we have tried are a micrometer oil (Price's 'Albaline') and glycerine; but the most successful is medicinal liquid paraffin, because it requires no special site or anti-vibration arrangements and yet flows fairly easily. The capillary curvature is also less extensive than that reported for water by Rayleigh. It is necessary to work with a clean surface and to shield it from air draughts. An interesting effect is the unusual response to vibrations observed in the neighbourhood of any sudden and marked change in the depth of the liquid layer.

An important item of the equipment we use is a simple plano-convex lens of 38 cm. diameter (*F*/5) acquired from war surplus stocks of optical components. This is arranged horizontally as the collimating lens of the Fizeau interferometer and directs a beam of parallel monochromatic light vertically downwards on to a lapped cast-iron surface plate of 30 cm. diameter supported on three levelling feet. The liquid paraffin layer, about 3 mm. in thickness, is floated on the metal surface and retained by paper strip gummed round the periphery of the plate. The disposition of the fringes which are produced by two interfering beams, one partially reflected from the liquid surface and the other totally reflected from the metal, is controlled with the levelling feet.

The three interferograms reproduced were obtained in mercury green light using exposure times of 5–20 sec. with Ilford *HP*2 plates (6 cm. × 4 cm.). No. 1 shows fringes—rather like a system of Newton's rings—produced over the lapped surface plate when symmetrically disposed to the liquid surface. The black border represents the boundary region from which no light is received owing to capillary curvature. This effect extends into the region from which light is received but vanishes at about 2·5 cm. from the boundary. No. 2 shows fringes over the same plate when slightly inclined to the liquid surface. The white disk represents the end of a 1-in. diameter Hoffmann roller standing in the liquid. A disturbance due to capillary curvature extends about 2·5 cm. outwards from the cylindrical surface which, like the gummed paper, is wetted by the oil.

As glass and liquid paraffin have nearly the same refractive index it is preferable to support glass plates over the liquid surface during examination. In No. 3 the widely spaced fringes are produced by interference in the air film between the liquid and the lower surface of a glass plate 1 cm. thick. The closely spaced system is due to the two surfaces of the glass plate itself and shows that it is wedge-shaped.

We direct attention to this use of a liquid surface as an interferometer mirror because it may have many applications, especially for studies of the physical properties of liquids. It has many obvious advantages as a ready means of verifying large flat surfaces of a precision character.

A fuller account of this work, forming part of the research programme of the National Physical Laboratory, will be published elsewhere.

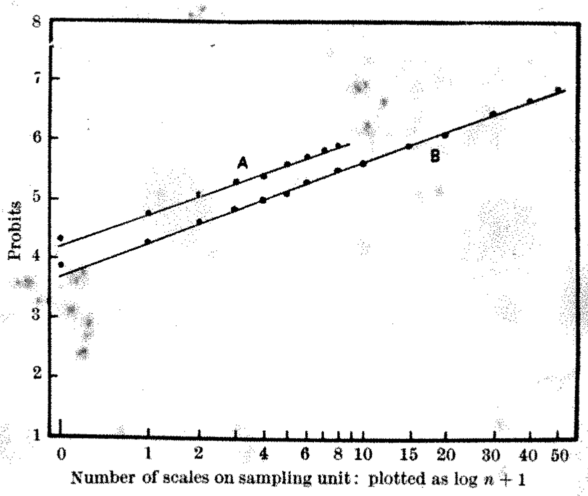
Truncated Log-Normal and Root-Normal Frequency Distributions of Insect Populations

In entomology it is usual to find that the numbers of insects or their eggs occurring in each sampling unit are not distributed normally, the many lesser and zero values causing the distribution to be extremely skewed. When such distributions occur, the gross deviations from normality invalidate the use of classical biometrical methods.

I have found such markedly skew distributions of the number of red scales (*Aonidiella aurantii* Mask.) on individual citrus leaves and of the number of eggs laid by *Anobium punctatum* females. It has been found that these two cases can be plotted as straight lines when the probit methods suggested by Gaddum[1] are used, and it appears that these methods may give a solution of other skewed distributions. The red scale data required a logarithmic transformation of the enumeration variable, the *Anobium* data, a square root transformation. The usual device of plotting $n + 1$ instead of the number n has been adopted to allow zero values to be plotted on a logarithmic scale.

As illustration of the degree of linearity achieved by probit methods, the data for red scales on citrus leaves as given in the table, and that of Upholt and Craig[2] for black scales on citrus twigs, have been so plotted in the figure.



Degree of linearity achieved by probit methods. Line *A*, black scales on citrus twigs (Upholt and Craig[2]). Line *B*, red scales on citrus leaves

Frequency distribution of red scales on 720 citrus leaves

Number of scales per leaf	Observed frequency	Number of scales per leaf	Observed frequency	Number of scales per leaf	Observed frequency
0	89	22	7	47	1
1	79	23	4	50	1
2	78	24	7	52	2
3	58	25	5	53	1
4	51	26	3	55	1
5	30	27	3	57	2
6	39	28	8	59	1
7	34	29	2	60	1
8	27	30	5	62	2
9	18	31	2	65	1
10	13	32	2	74	1
11	12	33	2	78	1
12	19	34	2	80	1
13	16	35	1	81	1
14	13	36	1	88	1
15	6	37	4	94	1
16	12	38	1	96	2
17	6	39	2	103	1
18	5	41	2	105	1
19	8	42	2	185	1
20	6	44	5	241	1
21	5	45	1		

Marked breaks and changes of slope occur with some published data; but these may be due to sampling of mixed populations.

The truncation to the left apparent in the figure can be eliminated by increasing the size of the sampling unit until zero values do not occur. When this was done with red scale using counting units of twenty leaves, it was found that the frequency distributions of these units were still log-normal. After the six twenty-leaf values of each of thirty trees had been transformed to logarithms, Nayer's test[3] showed that the various populations could be regarded as having a common variance and thus normal statistical methods could be used. The obvious method of overcoming difficulties arising from truncation of these curves is an increase in size of sampling unit; but if it is necessary to compare data already collected this device may not be available.

From the ease with which data can be reduced to a series of straight lines, it appears preferable to assess significance of differences between two or more sets by linear regression methods, rather than argue back to parent distributions. The usual methods of calculating regressions and their variance cannot be used because points other than the first are not independent. Methods of calculating regressions and variance of such transformed data do not appear to be available, but are required before the utility of probit methods in handling skewed distributions can be determined.

The data and plots of *Anobium* egg-laying are being published elsewhere[4].

Photographic Evaluation of Blackout Indices

DURING the act of blinking the pupils are masked by the upper lids for an appreciable fraction of a second (*c.* 0·1–0·3 sec.) and, in consequence, vision is intermittent. The *blackout index* expresses the percentage of vision during which one is unsighted, and is obtained from the ratio of the blackout and interblink periods, the normal average value of the latter being for men and women *c.* 3·3 sec. In conversation, the average interblink period is only *c.* 2·7 sec.[1].

Average time constants of blinking can be assumed for a large group of individuals, so that in group photography one can expect that at any instant a definite percentage of the subjects (the average blackout index) will be unsighted and have their eyes almost or wholly closed. Examination of group photographs of a total of sixty-one subjects revealed that roughly one-tenth of them were photographed during the act of blinking, in reasonable agreement with the expected result[2]; but it seemed desirable to examine further photographs of groups and thus obtain the average blackout index for people in general.

It is essential that the time of exposure should be less than the blackout period (that is, < 0·1 sec.), for blinks will not be revealed clearly in exposures greater than the duration of a blink (0·3–0·4 sec.). Occasionally, even in time exposures, the eyes may appear somewhat blurred. It is therefore important to ensure that such group photographs are either snapshots or flashlight photographs which satisfy the above condition. This is not always easy. Momentary exposures of a group of people occasionally reveal no blinks, whereas, especially with small groups, as many as one-half the subjects may have closed eyes. Many photographs are useless for the purpose in view, if the eyes of all the subjects are not clearly visible.

During the past year I have examined a large number of photographs to ascertain with greater accuracy the average blackout index for people in general. I have also examined many time exposures to confirm that they do not reveal blinks. No evidence of a blink was found in several group photographs taken about fifty years ago, all posed and certainly time exposures. A series of departmental group photographs of students taken during the past twenty-nine years, and all known to be time exposures, yielded only two instances of closed eyes in a total of more than a thousand subjects. Possibly these two were resting their eyes in anticipation of being photographed. On the other hand, in a large number of snapshot and flashlight photographs of a total of 2,140 subjects, 215 had closed eyes. On this evidence it seems certain that the general average blackout index does not deviate appreciably from 10·0 per cent for light-adapted eyes (pupil diameter, 3–4 mm.).

It follows that the general average *blackout period* will be 0·33 or 0·27 sec., according to which of the general average interblink periods (3·3 or 2·7 sec.) is used. As the conditions under which snapshot or flashlight photographs are taken are more often conversational than normal restful ones, the second value of the blackout period is likely to be the true one. This value lies between the limits mentioned earlier, and it is interesting to note that Miss M. P. Lord and W. D. Wright recently determined the former's blackout period to be *c.* 0·2 sec.[3].

It is clear that individual blackout indices could be determined by examination of a large number of random photographs of one and the same individual, though the process would be rather tedious. In a popular form of multiple photography, blinks can often be noticed—in one case I saw four in a total of forty-eight photographs—but it seems doubtful whether these multiple photographs are sufficiently random and unposed to serve as a basis for the determination of individual blackout indices.

Variation of Ground-Levels on Coe Fen, Cambridge

SOME interesting and considerable variations in level were noticed on Coe Fen, Cambridge, after the floods of 1947. A portion of the Fen is used by the Engineering Department, University of Cambridge, for practical exercises in surveying. For this purpose, concrete blocks approximately 1 ft. 0 in. square by 1 ft. 6 in. deep have been sunk into the ground to form the survey stations, the actual station being taken as the centre of a steel tube cast solid with the concrete block and projecting slightly above the surface of the block. These stations are grouped into closed polygons.

Small vertical movements of these blocks are known to take place, and have usually been attributed to frost heave. For this reason, the differences in level between all these blocks are carefully checked before the surveying course begins each summer, so that the accuracy of the students' levelling may be checked.

After the floods of 1947, during which practically the whole of this area was inundated, this check was carried out as usual, and very much larger movements than had hitherto been found were encountered. Unfortunately, the absolute levels of these blocks have never been measured with respect to some fixed and stable bench-mark, so that only their relative movements can be measured. However, between the summers of 1946 and 1947, either the south end of the Fen has lifted, or, more likely, the north end has sunk about 0·2 ft., a considerable amount in a distance of about 2,000 ft. The levels were rechecked in April of this year, and little difference was found from the previous year's figures, only slight movements, of the order of 0·03–0·04 ft., having taken place.

The nature of the ground was investigated in an endeavour to shed some light on the cause of these movements. Borings were made near three of the stations. At all these points, similar conditions were found. After about six feet of gravel, some clay was encountered. This was at first thought to be the thick underlying stratum of gault known to exist in this area. However, further boring revealed that this layer of clay was only about one foot thick, and that below this was a layer of what might best be described as liquid mud, into which the soil borer could be pushed by the weight of the body, without any twisting action being necessary. This liquid mud was about four feet thick. In some of the borings a layer of peaty substance was found at the bottom of the gravel.

Work-Hardening Under Complex Stresses

PLANE stress yielding was induced in a duralumin plate by expanding a 12-segmented cylindrical collet. The tangential strains in the plate were measured at ten values of radius by means of single-filament Minalpha resistance wire strain gauges[1]. At all loads the measured strains in the unyielded portion of the plate fitted the theoretical solution exactly. The measured values in the yielded zone from the inner radius out to the yield boundary are shown for a typical loading in the figure.

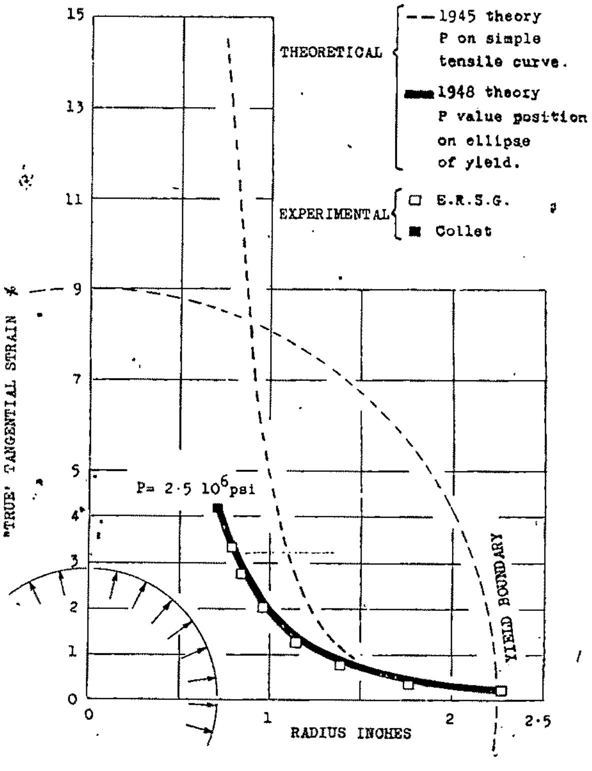
The experiment was designed to check the particular solution in my 1945 theory on post-yield stress-strain compatibility[2], but with the 1947 extension to any severity of deformation[3], since the experimental strains were large at the higher loads. The stress-strain relations for this plane-stress problem in polar co-ordinates (r, θ) are,

$$e_r = \frac{1}{E}(S_r - qS_\theta) + \int_{S_r^0}^{S_r}\left(\frac{1}{P} - \frac{1}{E}\right)dS_r - p\int_{S_\theta^0}^{S_\theta}\left(\frac{1}{P} - \frac{1}{E}\right)dS_\theta, \qquad (1)$$

with the expression for e_θ written by interchange of r and θ and in which e can be nominal strain for small strains or 'true' for any finite magnitudes[3,4], E the elastic modulus, P the inelastic modulus, S stress, q and p elastic and plastic transverse contraction ratios respectively, while superscript 0 denotes the stress operating when the element first yields. The stresses must satisfy the extended Huber – Mises – Hencky yield criterion[2]

$$S_r^2 - S_rS_\theta + S_\theta^2 = Y^2, \qquad (2)$$

the equations of equilibrium and the boundary con-



ditions as well as (1). The normal stress Y is 'equivalent' to the complex system.

Comparison of the measured strains with the theory showed that in the duralumin of the plate the stress-strain parameter P obeyed the relationship,

$$\frac{1}{P} = fY, \qquad (3)$$

with f of value $3 \cdot 57 \times 10^{-12}$ (psi)$^{-2}$. In the 1945 theory[2] P was taken as the slope of the simple tensile stress-strain curve at stress Y. Thus for duralumin in simple tension f is of value 172×10^{-12} (psi)$^{-2}$, and if this value is used in the theory would give the curve shown in the figure. It is important to note that this erroneous assumption is involved in all the recent theories in which the stress-strain parameters are assumed as functions of only octahedral shear stress[5,6].

The duralumin is 'stiffer' under the compression-tension stresses in the expanded plug test than it is under simple tensile stress. This led me to analyse tests by Davis[7] on thin-walled tubes under axial tension and internal pressure inducing tangential tension. Under the tension-tension stress loading the steel was 'less stiff' than under simple tension. Thus it appears that the strain change accompanying a stress change depends on the signs and magnitudes of the orthogonal stress components as well as on the equivalent normal or octahedral shear stress[8].

Genetics of Style-Length in *Oxalis*

AMONG the tristylic plants which have attracted the attention of geneticists, without the genetic situation being fully elucidated, is *Oxalis valdiviensis*. Two years ago, work was started in this Department by setting out twelve short-styled plants for open pollination by long, as this method had proved successful in the case of *Lythrum salicaria*.

Of the twelve progenies grown in 1947, six threw no mid-styled plants, giving 363 L : 319 S. The remaining six families, which contained mids, gave 24 L : 329 M : 336 S, showing that the short parent was segregating for a factor for mid style-length, though not so as to give a 1 : 1 : 2 ratio, as with *Lythrum salicaria*.

This result suggested the possibility that the genes for short and mid were rather closely linked, with about 6·8 per cent recombination, and that the shorts used had been double heterozygotes in repulsion. In order to test this view, we have grown in 1948 fifteen progenies from shorts from these families crossed again with long. On the linkage hypothesis, the expectation is that about 1 in 15 of such parents should have received the mid gene and that it, unlike its short parent, should be a double heterozygote in coupling, giving approximately 14 L : 1 M : 15 S.

The results of 1948 have completely verified this supposition. Fourteen of the progenies grown have given long and short only, in all 723 long and 675 short, while the remaining progeny has given 17 L : 2 M : 38 S, practically in the proportions anticipated.

These experiments do not complete the demonstration that *Oxalis valdiviensis* is disomic, unlike *Lythrum salicaria*, which has been shown to be tetrasomic. Such a conclusion is suggested by Lady Barlow's earlier work[1,2], and critical tests have been prepared for next year. If, however, the species proves to be disomic, the population maintained by legitimate pollination would contain one genotype long, two mid, heterozygous and homozygous respectively for the mid gene, and four short, including the two double heterozygotes in coupling and repulsion. Plants homozygous for the short gene could not be produced by legitimate pollination. In *Lythrum salicaria*, on the other hand, there are one genotype long, four mid and ten short[3].

In any event, the fact that the two controlling factors are here linked shows that the genetic situation is quite distinct from that in *Lythrum*, in spite of the two remarkable similarities that in both species the double recessives are long-styled, and in both the factor for short-style is epistatic to that for mid.

A detailed note of these experiments will be published in *Heredity*.

Microflora of the Rumen of the Sheep

IN a previous communication[1], McGaughey and Sellers stated that sheep, with permanent rumen fistulæ, fed on hay and mangolds, develop a rumen microflora similar to that described by Quin[2] as occurring in sheep in South Africa. They pointed out that the organism found overwhelmingly predominant and apparently that termed *Schizo-saccharomyces ovis* by Quin is motile, and is apparently the same organism as that described by Woodcock and Lapage[3] and now known as *Selenomonas ruminantium* (Certes).

We believe that the organism is not a Schizosaccharomycete, as a result of (*a*) the study of its morphology, for example, characteristic wriggling motility, bean shape, pointed ends and absence of endospores; (*b*) failure to grow in media usually found to be adequate for the culture of Schizosaccharomycetes. Woodcock and Lapage[3] in their detailed examination of *Selenomonas ruminantium* did not overlook the possibility of it being a yeast; but after examination of authenticated strains of Schizosaccharomycetes, decided that they were not related. Moreover, they mentioned that Ledingham[4] was unable to cultivate *Selenomonas ruminantium* on various media; our attempts at cultivation have been equally unsuccessful. Thus, plating on potato dextrose agar of a centrifugate containing 10^{10} selenomonads per ml. yielded as the most numerous types of organisms: Rhodotorulæ 5×10^6/ml., *Aerobacter* 3×10^6/ml., yellow and white cocci 1×10^6/ml., Bacilli 1×10^5/ml., *Candida*-like organisms 1×10^2 to 10^3/ml. After incubation of rumen contents mixed with dextrose solution, several other types of yeasts were isolated; these have not been fully identified, but none is a Schizo-saccharomycete.

As it is possible that the growth of bacteria and yeasts may inhibit the growth of selenomonads, single-cell culture methods were adopted. By micro-manipulation, four different morphological stages of *Selenomonas ruminantium* were transferred to each of the following media: potato dextrose agar, the same with addition of 20 per cent dextrose, synthetic medium with 2 per cent and 20 per cent dextrose added, potato dextrose agar with rumen filtrate (1 : 1) added. No growth whatever occurred after these transfers; indeed, contact with these media inhibited motility at once.

In addition to the media mentioned above, many others, inoculated with fresh motile selenomonad suspension and incubated aerobically, anaerobically, in carbon dioxide atmospheres, at low temperatures and high temperatures have been used without success.

The inferences from our culture studies are (1) *Selenomonas ruminantium* did not grow; (2) if Schizo-saccharomycetes had been present, they would have been observed.

Hence we believe that the predominant organism of the rumen is not a Schizo-saccharomycete. Further, we have found no evidence of Schizo-saccharomycetes in the rumen of sheep in Great Britain. We suggest that the term *Schizo-saccharomyces ovis*, as applied to the organisms in question, is misleading and should be discontinued.

British Folliculinidæ (Ciliata, Heterotricha)

SINCE February 1947, I have had the opportunity of making an intensive search for Folliculinids at Plymouth, where I found four species, and at Cullercoats where five species were discovered. Except for *Folliculina* (*Folliculinopsis ?*) *ampulla*, no record of Folliculinid species existed at these two marine laboratories. Besides the six species already recorded by me for Great Britain[1], a seventh species, *Folliculinopsis* (*Metafolliculina*) *andrewsi* (Hadzi), found by me both at Plymouth and at Cullercoats, should now be added to the list of British species.

The species recorded by me are: *F. producta*, *F. andrewsi*, *F. viridis* and *F. elegans* from Plymouth (list and specimens with Director, Plymouth Laboratory), and *F. producta*, *F. andrewsi*, *F. viridis*, *F. elegans* and *F. simplex* from Cullercoats (list with Director, Dove Laboratory). The only other records are *F. ampulla* and *F. elegans* from Port Erin (Bruce[2]), and a single species, *F. viridis*, from Swansea (Fowell[3]). The finding of *Folliculinopsis* (*Metafolliculina*) *andrewsi* (Hadzi) is the first record of the species on the east side of the Atlantic (the species being common around Woods Hole, United States), as well as a first record for Great Britain.

I shall be grateful for information regarding British records of other species of Folliculinidæ, which workers in marine laboratories may come across, to enable me to include it in the systematic account well under way for publication.

My thanks are due to Wing-Commander F. S. Russell for allowing me a table at Plymouth in September 1947, and to Prof. A. D. Hobson for facilities for work in the Marine Laboratory at Cullercoats during 1946–47.

Number of Sperms Required for Fertilization

MUCH has been done in recent years to determine the number of sperms which must be introduced by artificial insemination to maintain a normal rate of fertilization. There are, however, markedly divergent views as to the number of sperms normally present in the immediate vicinity of the eggs at fertilization. Such direct evidence as exists suggests very small numbers. Thus Hammond[1] reports finding remarkably few in smears prepared from the fallopian tube of rabbits killed 10 hr. after coitus. Hammond and Walton[2] examined the ovarian capsules of ferrets at 3–36 hr. after coitus, and counted 1,600 sperms in one ferret and 0–75 sperms in six others. The number of sperms in the tubes of rats were observed by Blandau and Money[3] to increase during the hour after coitus to a maximum of about 200.

On the other hand, it is a widely held theory that the eggs of many species of mammals must be freed from the surrounding mass of follicle cells, by means of hyaluronidase, before sperm penetration can take place, and there is a strong implication that a large aggregation of sperms is necessary to assure an adequate concentration of hyaluronidase. Pincus and Enzmann[4] stated that at least 20,000 sperms/c.mm. are required for follicle cell dispersal and fertilization *in vitro*, and Pincus[5] suggests that this may also be the case *in vivo*. Kurzrok, Leonard and Conrad[6] concluded from their studies that an accumulation of about 20 million sperms would be needed in the vicinity of the human egg *in vivo*.

It has been shown, however, that in the rat denudation of the egg is not a prerequisite of fertilization[7,8]. This would appear to remove the principal reason for supposing that large numbers of sperms are necessarily involved at fertilization. Further information on this matter has now been obtained.

When rabbits are artificially inseminated with $0 \cdot 5-1 \cdot 0 \times 10^6$ sperms and killed 12–15 hr. later, the eggs are frequently recovered in apparently intact masses of cumulus cells. Nevertheless, a proportion of the eggs show evidence of sperm penetration, and at 15 hr. the pronuclei can be discerned by means of the phase-contrast microscope. This confirms the observations previously recorded for the rat.

Attempts were made to count the number of sperms in the washings from the tubes of rabbits inseminated with about $1 \cdot 0 \times 10^8$ sperms. Accurate assessment is very difficult owing to the relatively large volume of fluid required for thorough washing; but it was estimated that about 2,000–4,000 sperms were present throughout the length of a single tube. The number in the immediate vicinity of the eggs must have been much smaller. Insemination with less than $1\cdot0 \times 10^6$ sperms, though resulting in the fertilization of a proportion of the eggs, greatly reduces the number of sperms in the tubal washings, so that even an approximate estimation was not found practicable.

Fertilization in the rat takes place in a distended portion of the fallopian tube, near the infundibulum. If the distension is incised the contents, including the cumulus masses, flow out freely, and it is likely that the special conditions prevailing permit the escape of the great majority of the sperms suspended in the fluid around the eggs. Systematic counts of sperms in this fluid and in the follicle cell-mass have been made in seven rats. The number of sperms varied from 9 to 101 in individual tubes, with a mean of 43.

Epididymal sperms were introduced into the fallopian tubes of rabbits 5–6 hr. before ovulation. Large numbers of sperms (about $2\cdot0 \times 10^6$) resulted in the fertilization of fourteen out of eighteen eggs (in four rabbits). With small numbers (1,140–1,600) four eggs were fertilized in a total of sixty-nine (in fourteen rabbits). This is a low rate of fertilization; but it should be noted that the dilutions to which the sperms were necessarily subjected (up to 1 : 2,000) had a deleterious effect upon them and about 50 per cent were immotile when introduced. Furthermore, in the 5–6 hr. before ovulation, considerable dispersion throughout the tube may have taken place, so that the number ultimately present at the site of fertilization must have been much less than the number introduced.

On the basis of these observations it is concluded that fertilization can take place when there are in the vicinity of the eggs less than a hundred sperms in the rat and less than a thousand in the rabbit.

My sincere thanks are due to the Medical Research Council and to Sir Charles Harington for the hospitality of the National Institute for Medical Research, and to Dr. A. S. Parkes for his invaluable criticism and advice.

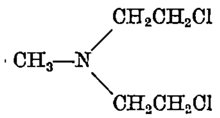
Inactivation of Complement by Nitrogen Mustard

The recent clinical use of the nitrogen mustards for the treatment of Hodgkin's and other neoplastic diseases[1] has focused attention on these compounds and more particularly on their biological action. The intensive study of these vesicants made during the War[2], when they were regarded as potential chemical warfare agents, has been continued in the hope that more information will be gained about their action on animal tissues and about the basis of their therapeutic effect.

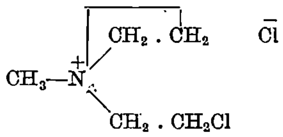
In some of our investigations we have studied the action of one of the most commonly used nitrogen mustards, methyl-*bis* (β-chloroethyl) amine (I), on complement, and have found that complement is rapidly destroyed or inactivated by the vesicant. This inactivation is similar in many respects to that effected by 'ordinary' mustard gas[3]. The amount of nitrogen mustard required completely to inactivate the hæmolytic complement of guinea pig serum at 37° is small, and the inactivation is not due to hydrochloric acid liberated by hydrolysis of the nitrogen mustard since the *p*H of the mixtures was maintained at about 7·5 throughout the reaction.

The addition of 2·5 mgm. of the nitrogen mustard hydrochloride to 0·50 ml. of guinea pig serum resulted in partial inactivation of the complement in 10 min. at 37° and complete inactivation in less than 30 min. Considerably smaller amounts of the nitrogen mustard can effect this inactivation; thus, 0·25 mgm. destroyed at least three-quarters, and 0·05 mgm. about half, of the complement activity of 0·50 ml. of guinea pig serum in 3 hr. and 6 hr. respectively at 37°. The inactivation, like that effected[3] by 'ordinary' mustard gas, ββ'-dichlorodiethyl sulphide, concerns all four components of complement, but the fourth component (that specifically inactivated by ammonia) appears to be less readily inactivated than are the others.

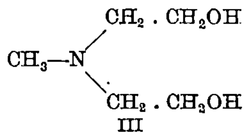
The nitrogen mustards quickly undergo chemical changes in solution[4,5], and the biological action of the parent substance appears to be due mainly to the capacity of some of these transformation products to react rapidly with certain tissue constituents. In aqueous solution methyl-*bis* (β-chloroethyl) amine (I) undergoes cyclization to form the corresponding very reactive imine (II); further cyclization and other changes follow more slowly, and the complete series of changes results in the production of several products, including methyl diethanolamine (III).



I
Nitrogen mustard
(Code No. HN2)



II
Ethylenimonium derivative of I



III
Methyl diethanolamine

In some of our experiments, we have tested the complement-inactivating power of 'hydrolysed' nitrogen mustard, that is, solutions of the vesicant which have been kept at 37° for varying lengths of time before addition to guinea pig serum. These experiments have shown that previous hydrolysis of the vesicant greatly reduces its capacity to inactivate complement, and that solutions kept for 3 hr. at about *p*H 7·5 and at 37° have lost most of their inactivating power. Methyl diethanolamine (III) in amounts up to 125 mgm./0·5 ml. of guinea pig serum has no significant complement-inactivating action, and the slight inactivating power of hydrolysed nitrogen mustard is probably due to the presence of a small amount of the original compound (I) in the solution, for it has been shown[5] that a 1 per cent solution of (I) kept at 25° for 70 hr. still contains about one-fifth of the unchanged compound. The toxic compounds formed from the nitrogen mustard in solution at *p*H 7·5 appear to differ from those which inactivate complement, for the activity of the former increases[6] as the solution is kept at 38° and *p*H 7·4 for 1–2 hr., whereas our experiments have shown that the complement-inactivating power decreases under these conditions.

The amount of nitrogen mustard we have used in our experiments is appreciably greater than that likely to be present in the blood after injection of the drug into patients suffering from Hodgkin's disease; but it is possible that the smaller amounts used therapeutically (for example, 0·1–0·2 mgm./kgm. injected daily for 4–6 days) may reduce the complement titre of the blood of the patients. We are therefore testing the serum of some of these treated patients and are carrying out similar tests on injected guinea pigs. A fuller account of these investigations will be given elsewhere.

We are indebted to the Medical Research Council for grants which have covered the expenses of this investigation.

Loss of White Cells in Bone Marrow Culture

MANY techniques of cell culture involve suspension of cells in some fluid medium, and incubation in sterile glass containers, with subsequent counting of the suspended cells. Although it has long been known that certain cells are 'sticky' and can adhere most firmly to glass surfaces[1], this fact seems to have been neglected in work with cell cultures, where some cells might be lost by irreversible adhesion to the walls of the culture vessel. The following is an attempt to investigate this point in bone-marrow culture; here adhesion is of particular importance because only certain types of hæmopoietic cells are 'sticky'.

The technique used has been previously described[2], and in essence consists of suspension and incubation of marrow cells in 80 per cent sterile serum. Comparison was made between cultures in ordinary clean glass bottles and cultures in bottles previously coated with silicone[3] to make the surface non-wettable and to prevent adhesion of cells. At all periods of incubation there was a consistently greater number of myeloid cells in the siliconed bottles, the difference being statistically significant and affecting myelocytes, band cells, and polymorphs; this difference was so great that, had silicone not been used, the increase in polymorphs due to maturation would have been missed (Fig. 1); lymphocytes and nucleated red cells showed no such effect. The loss of cells by adhesion amounted to about half a million in each bottle, and so was easily detected when the initial myeloid count was low (1,000,000 per bottle, or 500 per cub. mm.), but became statistically undetectable when the counts were higher (10,000,000 per bottle, or 5,000 per cub. mm.). This result is probably of some importance to those who are performing cultures with a low initial concentration of cells.

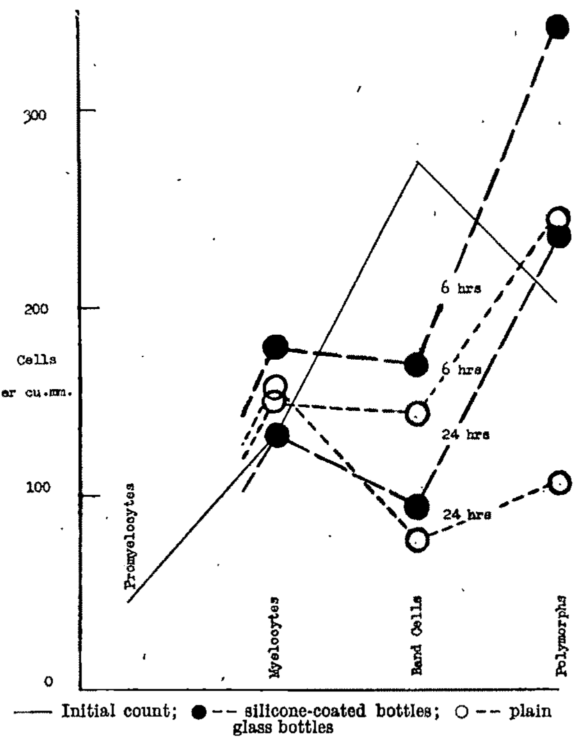

Fig. 1. Myeloid cell counts in marrow culture. Results after incubation for 6 and 24 hours in silicone-coated and plain glass bottles

Previously it had been noticed that there was an apparent increase in myeloid cells in cultures, when

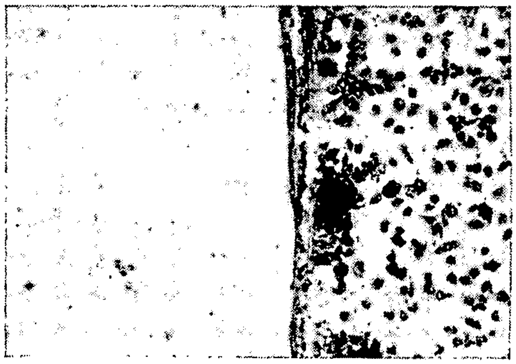

Fig. 2. Adhesion of leucocytes to glass coverslips (× 75). The left coverslip from a culture in heated serum; the right from a culture in unheated serum. Both after 48 hr.

the marrow specimens were suspended in reconstituted dried plasma or in serum which had been heated to 56° C. for one hour, instead of in unheated serum. As it is known that adhesion of leucocytes requires the presence of some thermolabile factor in serum[4], this effect was thought to be due to adhesion of the cells in unheated serum. To check this point, a grease-free coverslip was laid on the floor of each culture bottle, and was removed, washed in running tap water, and stained at the same time as the smears and total counts were made (that is, after 1–4 days). The photograph (Fig. 2) shows two such coverslips, the left from a 48-hour culture in heated serum, the right from a similar culture in unheated serum. The cells involved were always predominantly myeloid and monocytoid. No adhesion of nucleated red cells was ever seen. The density of the deposit was about 300,000 per square centimetre, this figure being of the same order of magnitude as that obtained from the silicone experiments.

Effect of Adenosine Triphosphate on Monolayers of Myosin

LITTLE is known about the behaviour of myosin in monomolecular layers. Communications previously published on this subject[1,2] appeared at an early stage of the study of myosin, that is, before Szent-Györgyi and his school[3] had shown that myosin consists of at least two different proteins, actin and myosin proper. In connexion with work in this laboratory[4] on the interaction between high-energy phosphate compounds and the different components of myosin, the investigations have been extended to monolayers of these proteins.
